sodium is sent into the stomach or into a pulmonary artery under orders to do the same as it does in the laboratory. The drug has in consequence had a short life after having been extolled in a very limited time by microscopists, etc." Jacobi concludes by saying that as an antidiphtheritic or antipyretic it utterly failed.

Frequent applications of pepsin, trypsin, or papayotin with a medicine-dropper may be indicated in some abstract cases. Naso-pharyngeal irrigation will cause the neighboring enlarged glands to become reduced in size quicker than all other treatment combined.

2. Sponging with peroxide of hydrogen hourly.

3. Internal administration of stimulant drugs, —ferric chloride for tonic effect. Alcohol, no matter at what stage, is indicated in all cases of septicæmia, be they diphtheritic or not.

4. Liquid diet,—milk, beef-tea, milk-punch; rectal feeding, if necessary.

5. Local applications of cotton swabs, moistened with bichloride (1 to 1000 to 1 to 500), applied with great pressure every two hours, as an abortive plan of treatment, if the case is seen early.

6. Antipyretics. If at all useful, salicylate of sodium is the best, in doses of 2 to 15 grains every hour or more, according to the age and tolerance of the patient. If the drug is not well borne, then antipyrin or antifebrin may be given.

The temperature in uncomplicated cases of diphtheria has given little trouble, except when complicated by scarlatina.

Cold applications—cracked ice and ice-cream—are very grateful to patients. Calomel, to empty the bowels and reduce the temperature, is a mercurial salt, besides being a valuable intestinal antiseptic. Orange- and lemon-juice are also highly beneficial.

The complications and their management must be considered in each case. So must the question of both intubation and tracheotomy, to which the author only refers. Every case must be studied, and the treatment based on the previous habits, the general condition, the severity of the attack, and the amount of the infection.

#### TREATMENT OF CHOREA.

In giving his views as to the treatment of chorea, DR. DUJARDIN-BEAUMETZ (*Bull. Gén. de Thér.*, March 15, 1894) first distinguishes between chronic chorea, which he points out as incurable, and acute chorea, or "chorée de Sydenham." The most common cause of the

latter is usually said to be rheumatism, but he thinks at the present time that the greater proportion of cases are of nervous or hysterical origin. The rheumatic and nervous influences often coexist in the same patient. He also points out that while in some inco-ordination is the leading phenomenon, in others loss of motor power is the most marked feature.

In chorea owning a rheumatic origin salicylate of sodium often fails. Antipyrin is the best remedy. Of this, 15 grains may be given four times daily. He has tried exalgine in doses of 45 grains daily, but without success, though Dana and Loewenthal, giving larger quantities (60 to 100 grains daily), have reported it useful.

Cure by antipyrin takes fifteen to twenty days to accomplish. In severe cases it is necessary to give hypnotics, and chloral is the best, the more so as it is well borne in large doses by children; as much as 45 to 60 grains daily may be given to infants.

If, on careful examination, no cardiac disease is present, the cold douches may be employed, or ether spray along the spinal column. In the period of the decline of the attack, massage and gymnastics are useful.

In chorea of hysterical origin the treatment should be quite different. Young girls of from twelve to fifteen are mostly attacked with this form of chorea, and other indications of hysteria, such as anæsthesia, are often present. Bromide of potassium, in doses of 30 to 60 grains daily, is here the best remedy, and arsenic may be given at the same time. Hydrotherapeutic treatment should be employed; the cold douche to the vertebral column, followed by a warm douche upon the lower extremities, is a good form. If there be much nervous excitation, the douche should be tepid. In very severe chorea of this kind the cold wet sheet should be used for ten or fifteen seconds, after which the patient should be surrounded by hot coverings; ether spray along the spinal column may be employed when other means cannot be adopted or when the patient supports the wet sheet badly. Massage as gymnastics may be employed here as in other forms of chorea. In that form of chorea in which muscular weakness is the most marked feature the bromide is not advisable; the cold wet sheet is the best means of treatment. With regard to other means that are employed, Dujardin-Beaumetz expressed himself as opposed to powerful drugs, such as strychnine, curare, etc. Choreia, he says, tends to get well itself, and it is not wise to interfere too actively.—*Medical Chronicle*, April, 1894.

*VERATRUM VIRIDE AS A REMEDY IN PUERPERAL ECLAMPSIA.*

DAVIS records the results of the use of veratrum viride during twenty years' practice, in the *Virginia Medical Monthly* for April, 1894.

The author's object in writing is to show that veratrum viride will control puerperal convulsions when administered in large doses, and that it is perfectly safe to administer it in sufficient quantities to control any case of convulsions, and he has reported a few cases to prove that his remarks are based not only upon a theory, but upon actual experience.

In conclusion, he states that he has used the tincture of veratrum viride successfully in the treatment of every form of convulsion except traumatic tetanic convulsions, and he does not hesitate to use it in conjunction with other remedies in such a case whenever he has an opportunity, with the hope of relief.

He claims to have used veratrum viride in larger doses than it was generally known that it could be used at the time he commenced to use it in the treatment of convulsions. He had never seen it recommended in such quantities (20 to 60 drops), and hence used it on his own responsibility. His experience convinces him that it is both safe and efficient in the treatment of convulsions.

*GUAIACOL AS AN ANTIPYRETIC.*

FRIEDENWALD and HAYDEN report a series of cases in which they have used guaiacol for this purpose. They think they are justified in concluding,—

1. That this drug has a powerful antipyretic action, occasioning a reduction of from one to four degrees of temperature in from one to four hours.

2. That in all cases this reduction of temperature is accompanied by profuse diaphoresis, which may or may not be accompanied by a chill or chilly sensation.

3. That great exhaustion is frequently produced.

4. That the effects may be obtained from comparatively small doses (from 30 to 50 drops), and that great care should, therefore, be exercised in the use of the drug. The drug should be applied but once or twice daily, and the initial dose should not be above 30 drops.

5. That the effect produced by guaiacol, though more powerful, is the same as is obtained from most of the other antipyretics of the coal-tar series, and that the same care must, therefore, be exercised as with the other

preparations. Its effect differs widely from the stimulating cold bath in being depressant.

6. That the main indication for its use is in diseases accompanied by high fever in which the cold bath cannot be applied. It may, therefore, be especially useful in typhoid fever as well as in all other diseases accompanied by high fever in which irritability of the stomach prevents the use of other antipyretics.

*TREATMENT OF TUBERCULAR PERITONITIS.*

DR. CARL BECK, of New York, read a paper with this title before the Eleventh International Medical Congress, the conclusions of which were as follows:

1. A diagnosis of tubercular peritonitis in the early stages is possible only in exceptional cases.

2. The injection of an iodoform-glycerin mixture (1 to 10) into the abdominal cavity has a specific antitubercular action.

3. As this treatment is useful in other peritonic troubles, it is particularly indicated in all doubtful cases.

4. The employment of iodoform in powder or solution is indicated after laparotomy whenever it is desired to limit secretion.

5. The absorption of the products of streptococci appears to be made less virulent in its results by the coabsorption of iodoform.

Of five cases of general peritonitis treated in this way, only one resulted fatally.

*ADMINISTRATION OF ANÆSTHETICS CLINICALLY CONSIDERED.*

WHITE (*Medical Press and Circular*, March 14, 1894) ends a paper with the above title as follows:

We should as a preliminary step endeavor by every possible means to encourage a patient in the prospect of an operation, to remove any undue fear, and to render him tranquil at the time of administration.

For three or four hours before the use of an anæsthetic no food should be taken, unless it be a few spoonfuls of liquid nourishment, or vomiting, with its ill consequences, is almost sure to take place.

The patient should always, if possible, be placed in a horizontal posture. All tight clothing should be carefully set free or removed, and the neck and chest of the patient relieved of the slightest pressure. The undivided attention of the anæsthetist should be

given to the patient during the whole period of administration.

The patient should be kept as quiet and cheerful as possible when inhalation is begun. There should be no noise about him, and he should never be spoken to or disturbed until sleep takes place.

Inhalation should be commenced very gradually, beginning with a free admixture of atmospheric air, and the proportion of anæsthetic vapor slowly increased.

If struggling occurs, we should admit more air or remove the inhaler. When struggling subsides, we should gradually resume the anæsthetic and endeavor to maintain regular breathing until the conjunctiva begins to be insensible; then the pupil oscillates between dilatation and contraction and the eyeball slowly rolls in its orbit.

The eyeball then becomes fixed; the conjunctival reflex becomes more and more feeble and then disappears. The pupil will now be found to be fully contracted and the condition of *sleep* is attained.

This condition of sleep can be kept up for a considerable time. As soon as there is full contraction of the pupil the inhaler should be removed, and gently reapplied if the pupillary contraction passes off and the eye begins to move. This renewed movement of the eyeball and diminishing contraction of the pupil invariably usher in returning consciousness.

The movements of the pupil and of the eyeball and the conjunctival insensibility *pass off in an inverse order to that of their accession*, and afford the most accurate guide for any necessary renewal of the anæsthetic.

An operation should never be commenced until this condition of sleep is reached. The slightest disturbance of a patient, either by noise, or by a slight puncture, or by movement, will so rouse him as to render him dreamy and excited, and will generally produce a depressing action both on the respiration and the pulse.

If stertorous breathing should occur, with fixed eye and dilated pupil, inhalation should immediately be stopped.

We should never, unless necessary, attempt to rouse a patient suddenly from his sleep by slapping, etc. The free admission of air to the apartment and to the face and cheek of the patient, and, if necessary, gentle application of ammonia to the nostrils, are the best restoratives in ordinary cases of *excessive* anæsthesia. And, lastly, we should most carefully watch the state of respiration and pulse and the condition of the pupil and aspect of the

countenance during the whole period of inhalation; and if the respiration or pulse fail, we should have immediate recourse to artificial respiration, free admission of air, and application of ammonia to the nostrils, and, if necessary, we should gently but regularly maintain artificial respiration for at least half an hour.

White believes that there is, as stated by the chloroform committee of the Royal Medical and Chirurgical Society, a considerable advantage in the use of mixtures of ether and chloroform over that of chloroform alone.

For many years he has employed the A. C. E. mixture almost exclusively, and has given it in nearly fifteen hundred cases. It is certainly less depressing than chloroform and not appreciably more irritating to the pulmonary mucous membrane. He has so far never seen any but the most favorable results from its use, and believes it is decidedly more free from danger than chloroform by itself.

#### THE DIGESTIVE ACTION OF PAPAIN AND PEPSIN COMPARED.

As a result of some experiments with papain and pepsin, as to their solvent and peptonizing action on egg albumin, DOTT (*Pharmaceutical Journal and Transactions*, March 10, 1894) notes the following:

1. One hundred grains of albumin, freshly boiled and sifted, digested in one ounce of water, with ten minims of dilute hydrochloric acid, at a temperature of 98° to 100° F., with two grains of pepsin. Solution was nearly complete in an hour. After four hours, one drachm of nitric acid, diluted with three drachms of water, was added; the precipitate, collected, washed, pressed gently in blotting-paper, and weighed in the moist state, equalled ten grains.

2. The same experiment in all respects, except that seven grains of papain were used. The nitric acid precipitate (including undissolved albumin) equalled one hundred and three grains.

3. One hundred grains of egg albumin, with one ounce of water, fifteen minims of dilute hydrochloric acid, digested at 130° F., with two grains of pepsin. Solution was nearly complete in fifteen minutes. After two and a half hours the practically clear solution was mixed with thirty minims of nitric acid, diluted with two drachms of water. The precipitate, collected and weighed, as above noted, equalled two and a half grains.

4. The same experiment in all respects, except that two grains of papain were used.

After two and a half hours the albumin was not nearly dissolved. It was collected and weighed in the moist state, equalling seventy grains. The filtrate from this precipitate was then mixed with nitric acid, as above described; precipitate collected, etc., equalled thirty-three grains.

From these experiments it is evident that papain has only a slight solvent action on albumin at the temperature of the body, and practically no peptonizing action. On the other hand, pepsin has a high power both of dissolving albumin and peptonizing the solutions. The higher temperature of 130° F. (as in the British Pharmacopœia's test for pepsin) increased the rapidity both of the solvent and peptonizing power of pepsin, and likewise increases the solvent power of the papain.

Certain assumptions are made: first, that the pepsin and papain of two well-known makers are what they are represented to be; second, that non-precipitation by nitric acid is a trustworthy indication of the formation of peptone.

#### PREScriptions.

Useful in painful dyspepsia:

℞ Bismuthi subnitrat., gr. x;  
Magnes. carbonat., gr. xv;  
Liq. potassæ, ℥x;  
Acid. hydrocyan., dil., ℥iii;  
Tinct. zingiberis, ℥v;  
Aq. menth. pip., q. s. ad ℥i. M.

For one dose. To be repeated two of three times daily. Shake well.

A cardiac stimulant:

℞ Tinct. strophanthi, ℥xl;  
Tinct. zingiberis, ℥i;  
Syr. simplicis, ℥iss;  
Aque chloroformi, q. s. ad ℥viii. M.  
2 tablespoonfuls three times a day.

An application for eczema:

℞ Ol. amygdalæ dulc.,  
Glycerini, of each, ℥iii;  
Zinci oxidi, ℥iss. M.

A good nutrient enema:

℞ Egg, one;  
Fresh milk, ℥iv;  
Pancreatic solution, ℥ii;  
Sodium bicarbonate, gr. xx;  
Hot water, ℥ii.

Switch the egg and milk thoroughly together, add the pancreatic solution and bicarbonate of sodium, then the hot water, and let stand in a warm place for half an hour. A little brandy or wine may be added, if desired. The addition of a few drops of laudanum frequently assists in the retention of the enema.

Caustic for nævi, tuberculous growths, etc.:

℞ Sodii ethylatis, ℥i;  
Alcohol, ℥i. M.  
Apply with care.

The following will be found useful in promoting the contraction of fistulous tracts:

℞ Camphoræ, ℥i;  
Salolis, ℥ss;  
Etheris, ℥i. M.

For uterine hemorrhage:

℞ Ext. cannabis indicæ fl., ℥viii;  
Ext. ergotæ fl., ℥i;  
Ext. hamamelis fl., ℥ss;  
Tinct. cinnamomi, ℥ss;  
Aq., ad ℥iii. M.  
2 tablespoonfuls every three hours.

—*Medical Press and Circular*, March 7, 1894.

#### PRESCRIPTIONS AND PRACTICAL NOTES.

Alopecia:

Oil of cinnamon, ℥iiss;  
Sulphuric ether, ℥i.  
Paint twice a day.

Acute tonsillitis:

Crystallized carbolic acid,  
Camphor, of each, gr. xv;  
Dist. water,  
Glycerin, of each, ℥ii.  
Paint on the tonsils.

Anæsthetic, local:

Chloroform, ℥i;  
Ether, ℥vi;  
Menthol, gr. xxx.  
To be applied by a spray.

*Bensonaphthol*.—In bowel- and stomach-troubles of children this substance should be exhibited five times a day, according to the following total daily dosage:

Age.	Grains.
0 to 6 months.....	3 to 7½
7 to 12 months.....	9 to 12
1 to 3 years.....	13
4 to 7 years.....	22½
8 to 14 years.....	30

Tuberculous bronchitis:

Creosote, ℥ss;  
Tinct. of cinchona, ℥i;  
Pure chloroform, ℥ss;  
Malaga wine, q. s. ad ℥iv.

A teaspoonful three times a day before meals.

Burns:

Olive oil, ℥ii;  
Salol, ℥iii;  
Lime-water, ℥ii.

## Conjunctivitis (granular) :

Mercuric oxide, gr. iii;  
Zinc oxide,  
Thymol,  
Muriate of cocaine, of each, gr. iss;  
Camphor, gr. ss;  
Vaseline;  $\mathfrak{z}$ i.

*Erysipelas*.—Dr. H. Koster covers the affected part and its immediate neighborhood with a moderately thick layer of vaseline, over which is placed a piece of linen and a gauze binder. The dressing is applied twice a day.

## Emmenagogue :

Oxalic acid, gr. xx;  
Glycerin,  $\mathfrak{z}$ iss;  
Syrup of orange-flowers,  $\mathfrak{f}\mathfrak{z}$ ii;  
Distill. water enough to make  $\mathfrak{f}\mathfrak{z}$ xii.  
Dose.—2 ounces every hour.

## Gonorrhœa :

Antipyrin, gr. xxx;  
Corrosive sublimate, gr. ss;  
Water to make  $\mathfrak{f}\mathfrak{z}$ viii.  
Injection.

## Gonorrhœa (chronic) :

Tannin,  
Iodoform, of each, gr. xxx;  
Glycerin,  $\mathfrak{z}$ i;  
Rose-water,  $\mathfrak{z}$ iv.  
Injection.

## Hæmoptysis :

Gallic acid,  
Ergotin, of each, gr. xv;  
Distilled water,  
Syrup of marshmallow, of each,  $\mathfrak{z}$ i.  
Dose.—1 ounce every two hours.

## Hemorrhoids.—(a) Ointments :

1. Cold cream,  $\mathfrak{z}$ ss;  
Tannin, gr. xxx;  
Extract of opium, gr. iii.
2. Lard,  $\mathfrak{z}$ i;  
Goulard's cerate,  $\mathfrak{z}$ ii;  
Antipyrin, gr. xlv;  
Extract of belladonna,  
Extract of opium, of each, gr. xv.
3. Cacao-butter,  $\mathfrak{z}$ iii;  
Milk of almonds,  $\mathfrak{z}$ ii;  
Extract of hamamelis, gr. iii.
4. Vaseline,  $\mathfrak{z}$ i;  
Tannin, gr. xx;  
Muriate of cocaine, gr. xv;  
Sulphate of morphine, gr. iv;  
Sulphate of atropine, gr. iii.
5. Aristol, gr. xxx;  
Balsam of Peru,  $\mathfrak{z}$ i;  
Simple ointment,  $\mathfrak{z}$ i.

## (b) Suppositories :

1. Aristol,  $\mathfrak{z}$ i;  
Extract of opium, gr. ii;  
Extract of belladonna, gr. ii;  
Muriate of quinine, gr. xv;  
Cacao butter,  
White wax, of each, a sufficiency to make six suppositories.
2. Lard, gr. xxx;  
Extract of hyoscyamus,  
Extract of conium, of each, gr. ii;  
Cacao butter, a sufficiency for one suppository.
3. Chrysarobin, gr. i;  
Iodoform, gr. iii;  
Extract of belladonna, gr.  $\mathfrak{x}$ lv;  
Cacao butter, a sufficiency for one suppository.

## Iodoform powder (antiseptic and non-irritant) :

Powdered iodoform,  $\mathfrak{z}$ ii;  
Salicylic acid (powdered),  
Subnitrate of bismuth, of each,  $\mathfrak{z}$ vi;  
Camphor,  $\mathfrak{z}$ iss.

## Megrim :

Phenacetin, gr. xlv;  
Caffein sodio-salicylate, gr. iii;  
Muriate of quinine, gr. x;  
Saccharin, gr.  $\mathfrak{x}$ lv.  
Divide into ten powders.  
Dose.—1 powder every two hours.

## Tænia :

Chloroform,  $\mathfrak{z}$ i;  
Croton oil, gtt. i;  
Glycerin,  $\mathfrak{z}$ i.  
For one dose.

## Sickness (pregnancy) :

1. Bromide of strontium, gr. xx.  
Twice a day before meals.
2. Menthol, gr. xv;  
Alcohol,  
Simple syrup, of each,  $\mathfrak{z}$ i.  
A teaspoonful every hour.

## Sweats (night-, in phthisis) :

Salicylic acid,  $\mathfrak{z}$ ss;  
Distilled water,  $\mathfrak{z}$ iiss;  
Alcohol,  $\mathfrak{z}$ iss;  
Glycerin,  $\mathfrak{z}$ i.

Dose.—30 minims subcutaneously for four or five consecutive evenings.

## Ulcers (syphilitic) :

Calomel,  
Oxide of zinc, of each, gr. xv;  
Vaseline,  $\mathfrak{z}$ vi.

## PRESCRIPTIONS.

For chronic lead-poisoning :

- ℞ Magnesii sulphatis, ℥ss;  
 Potassii iodidi, ℥i;  
 Sodii sulphatis, ℥ii;  
 Syrupi aurantii, f℥ss;  
 Aquæ menthæ piperitæ, q. s. ad f℥viii.  
 Misce et fiat mistura.  
 2 tablespoonfuls three times daily.

For the green diarrhœa of infants :

- ℞ Acidi lactici diluti, ℥iv;  
 Tincturæ limonis, ℥i;  
 Syrupi simplicis,  
 Aquæ, of each, ℥ii. M.

A teaspoonful thrice daily after suckling.

A confection for gonorrhœa :

- ℞ Potassii bicarbonatis,  
 Potassii nitratis, of each, gr. v;  
 Pulveris cubebæ, gr. xxx;  
 Olei santali, ℥xx.  
 Fiat confectio.

A gargle for simple tonsillitis :

- ℞ Sodii biboratis, ℥iss;  
 Tincturæ benzoini, ℥iiss;  
 Aquæ rosæ, q. s. ad ℥viii.  
 Fiat gargarisma.  
 To be used frequently.

For commencing infantile broncho-pneumonia :

- ℞ Ammonii acetatis, gr. viiss;  
 Tincturæ aconiti, ℥xv;  
 Syrupi codeinæ (Pharm. Gall.), ℥ii;  
 Aquæ, ad ℥ii.  
 Fiat mistura.

A teaspoonful hourly till the dyspnoea is relieved.

—*Practitioner*, April, 1894.

## PRESCRIPTIONS.

Local dressings for burns :

1. ℞ Cocainæ hydrochlor., 1 part;  
 Acid. carbolic, 2 parts;  
 Acid. borici, 10 parts;  
 Glycerini, 17 parts;  
 Aq. destill., 70 parts. M.
2. ℞ Acid. borici, 4 parts;  
 Iodoformi, 2 parts. M.
3. ℞ Acid. borici, 3 parts;  
 Iodoformi, 2 parts;  
 Aristol, 1 part. M.

For laryngismus stridulus :

- ℞ Chloral. hydratis, ℥ss;  
 Pot. bromidi, ℥ii;  
 Syr. tolutani, ℥iiss. M.  
 A teaspoonful every half-hour.

Useful in general infantile eczema :

- ℞ Hydrarg. ammoniati, gr. x;  
 Acid. carbolic, gr. viii;  
 Ol. olivæ, ℥ss;  
 Ung. petrolei,  
 Ung. zinci oxidi, of each, ℥ss. M.  
 Apply two or three times daily.

For cancer of the cervix uteri :

- ℞ Iodoformi, gr. xv;  
 Extracti opii, gr. viii;  
 Essentiæ bergamottæ, ℥x.  
 Ol. theobrom., ℥iiss. M.

To make twelve suppositories; 1 to be introduced into the vagina when necessary.

For alopecia :

- ℞ Quinina sulphatis, gr. xl;  
 Tinct. cantharidis, ℥i;  
 Sp. ammon. aromatici, ℥i;  
 Ol. ricini, ℥iiss;  
 Ol. rosmarini, ℥vii;  
 Sp. vini rect., ℥v.

Shake well before applying once a day.

Chlorosis from menorrhagia :

- ℞ Sulphate of iron, gr. c;  
 Ext. hydrastis canadensis, gr. c;  
 Ext. hyoscyamus, gr. l.

Divide into one hundred pills; 2 to be taken at each meal.

—*Medical Press and Circular*, April 18, 1894.

## APHRODISIAC TREATMENT IN WOMEN.

LUTAUD points out in the *Journal de Médecine de Paris* for March 18, 1894, that patients frequently present themselves needing stimulant sexual treatment. Aside from general hygienic recommendations, the following methods may be carried out :

- ℞ Extract of nux vomica,  
 Extract of cannabis indica, of each, gr. xv;  
 Aqueous extract of aloes, gr. iii.  
 Make into fifty pills; take 1 after meals.

If phosphorus is indicated, the following may be used :

- ℞ Phosphorus, gr. ss;  
 Bisulphide of carbon, gtt. xx;  
 Sweet oil of almonds, ℥vi;  
 Magnesia, a sufficient quantity.

Make into fifty pills and coat with gelatin; 1 or 2 may be taken with meals.

Small doses of opium, say  $\frac{1}{4}$  grain of the extract, one hour before retiring at night, are sometimes recommended. In other instances, unless there is danger of producing the habit, cocaine may be employed. Where the trou<sup>1,1a</sup>

lies in hyperæsthesia, local treatment may be necessary, either operative or anæsthetic. In many instances hydrotherapy is exceedingly useful.

In the way of diet, fish, shell-fish, condiments and vanilla, and similar substances are useful. Electricity is of comparatively little value.

#### THE TREATMENT OF TYPHOID FEVER IN CHILDREN.

In the *Journal de Médecine de Paris* for March 18, 1894, there was an article upon this subject, in which the following treatment is recommended. At the onset of the attack, when the diagnosis is still uncertain and resembles in some respects the fever due to gastric disorder, it is well to administer small doses of calomel with a little milk sugar, and to give a rectal injection of an infusion of chamomile in boiled water, with four per cent. of boric acid, morning and night. Internally, to give from a coffee- to a dessertspoonful every two hours of the following prescription :

R Benzonaphthol, gr. xiii to gr. xxx;  
Syrup of peppermint, ℥i;  
Syrup, ℥iv.

In the way of nourishment, the patient may be given every two hours a very small cup of milk, to which may be added as a stimulant a little coffee, tea, cognac, or a very slight flavoring with vanilla or chocolate. In cases where the diagnosis is thoroughly assured after the calomel has acted, it is well to prescribe citrate of magnesium to move the bowels and large rectal injections morning and night of a borated solution already named ; or,

R Naphthol, gr. iii;  
Boiled water, Oii.

To be used in four equal quantities.

Internally, an antiseptic dose, composed as follows, is useful :

R Benzonaphthol, gr. xv to gr. xxx;  
Salicylate of magnesium, ℥ss to ℥i;  
Syrup of peppermint, ℥vi.  
Simple syrup, ℥iv.

If there is a bitter taste, it is well to replace the salicylate of magnesium by the salicylate of bismuth. Of this mixture, give a teaspoonful every two hours, and morning and night administer a capsule or cachet containing 2 to 4 grains of the hydrochlorate of quinine, or else give the same dose by injection or suppositories. If the headache is severe, replace the quinine by antipyrin ; spongings with tepid water may be

resorted to, and care should be taken, by the use of a boric-acid mouth-wash, to keep the mouth clean. If the fever is of great intensity, the same treatment, with the addition of constant spongings with cooler water, is to be followed, and should the nervous disturbance be very great, small doses of coffee or of chloral may be used, but antipyrin is not to be employed. In grave cases the baths are given even more frequently, as often as is necessary to keep the temperature down. For the nervous agitation the following mixture may be prescribed :

R Hydrate of chloral, gr. vi to gr. xv;  
Tincture of musk, gtt. xx to gtt. xl;  
Syrup of orange, ℥i;  
Water, ℥iii.

Cold compresses are to be applied to the head, if there is delirium. In cases showing marked adynamia, the cold should be applied to the head and the following mixture given :

R Hoffmann's anodyne, gtt. x to gtt. xv;  
Malaga wine, ℥i;  
Syrup of mint, ℥i;  
Water, ℥iii.

A teaspoonful to a tablespoonful every hour.

In cases of typhoid fever in which there seems to be great cardiac depression, the pulse being feeble and showing evidences of collapse, it is well to use the following injection hypodermically morning and night :

R Caffeine, gr. xxx;  
Benzoate of sodium, gr. xlv;  
Distilled water, enough to make ℥i.  
10 to 20 minims of this may be used.

Where complications such as bronchitis, broncho-pneumonia, etc., arise, the same treatment is to be continued as that just given, but the cold spongings are to be stopped and a cotton jacket is to be applied to the chest. Morning and night a mustard sinapism should be applied to the chest and the stimulating treatment already indicated employed.

During the period of convalescence the baths are diminished as the temperature approaches the normal. Soups, broths, and thoroughly softly cooked meats and pulpy vegetables are allowed, and the following tonic mixture given in the dose of a dessertspoonful three times a day :

R Tincture of gentian,  
Tincture of cinchona, of each, ℥v;  
Fluid extract of kola, ℥lxxv.

Champagne also is sometimes useful if it agrees with the patient. Should hemorrhage from the intestine complicate the case, absolute

rest, with local application of cold, is to be resorted to. Small doses of opium may be administered by the mouth, and every two to three hours 2 or 3 drops of perchloride of iron are to be employed. Ice compresses should be applied over the belly. Where there is danger of sloughs and abscesses, it is well to wash the part with a four-per-cent. solution of boric acid, and afterwards apply iodoform or salol. Abscesses, of course, should be opened, drained, and irrigated with mild antiseptic solutions. For the prophylaxis of typhoid fever, the discharges of the patient should be received in a five-per-cent. solution of sulphate of copper or in a 1 to 1000 solution of bichloride of mercury. The milk which is taken by the patient should be carefully sterilized, and after the case recovers careful disinfection of all the vessels used by the patient should be carried out.

#### WARM BATHS.

The *Medical Press and Circular*, April 25, 1894, states that Wick read a paper on the effects of warm baths on the temperature. He said the specific heat of the body was reduced when the bath was between 31° and 34° C., but the reduction was not parallel with the time or temperature of the bath. The pulse was increased when the temperature of the bath rose to 37° C., but was unaffected between 34.8° and 36.4° C. The specific heat is increased during the first half-hour, but gradually becomes less thereafter. The amount of direct heat depends a good deal on the conductivity of the tissues, as proved by experiments on the dead body, which shows that the heating is in the ratio of geometrical progression. The true heating agent in the body is through the circulation.

There are other factors, as radiation, conduction, and evaporation, which he maintains to be most important, as in breathing, perspiration, etc. The latter is adapted for the packing treatment as the perspiration is abstracted from the blood. All these conditions must be accepted as arbitrary, as the body will soon accommodate itself to the treatment by warm baths, and fail to act either by evaporation, radiation, or conduction.

It may be approximately stated that the pulse is increased ten beats per minute by increasing the temperature to 40° C., while the skin is greatly reddened.

Another point of investigation was the effect on the metabolism of the body. The body-weight begins to decrease after commencing the warm-water treatment, falling 350 to 500

grammes; after which it begins to increase if treatment be continued, till the body has reached 500 to 600 grammes more than it weighed at the commencement. The loss is greatest at the commencement of the treatment, and is more rapid than the increase. The nervous system is in no way irritated by the treatment. The quality of the pulse, measured by the sphygmograph, shows no weakening of the arteries, as is generally assumed, the hæmoglobin is increased, the blood is not subsequently thickened, the leucocytes are increased, the breathing is longer and deeper, and the sensation of the skin is soon restored.

#### TREATMENT OF TRAUMATIC EPILEPSY.

DARBY, in the *Virginia Medical Monthly* for May, 1894, states that the only remedies to be relied on in the treatment of traumatic epilepsy is the trephine in depressed fractures and the scalpel in other traumatisms which may produce reflex irritation of this character, and when the bone is removed in fractures, the dura should be opened, and if the cortex of the brain shows signs of injury, it should be carefully cut away and the wound stitched with catgut and closed antiseptically. When the bone is not cut away in small bits, it may be replaced in the opening and expected to cause no trouble, provided the button is not thicker than the surrounding bone. Prevention is better than cure, and it should be the purpose of the surgeon to prevent these phenomena by operation in all cases of depressed fracture as soon as he sees them, as the operation is more simple at that time, and if a button of bone has to be removed, he can usually select the locality for his trephine, and thus keep away from dangerous areas, such as the meningeal arteries and sinuses, as well as preventing strong adhesions of the dura and the development of epilepsy. After surgical operations for this disease, the patient should be kept on medical treatment for at least two years to prevent a return of the trouble. It is in this class of cases that we may reasonably expect good results. Bromide of potassium, in full doses, has given the best results, but of late a solution of bromide of gold and arsenic, given in 5- to 10-drop doses, has given very satisfactory results. The patient should, if possible, be induced to live a temperate and systematic life, sleeping regularly, eating moderately, and keeping his digestive and excretory organs in a healthy condition. Especially is it necessary for him to abstain from the excessive use of tobacco and alcoholic stimulants.

*OPHTHALMIA NEONATORUM.*

AUGUSTUS P. CLARKE (*Journal of the American Medical Association*, April 28, 1894) considers one of the most important indications in the treatment of ophthalmia neonatorum the removal, at short but regular intervals, of the purulent secretion, either by syringing or by prolonged irrigation through some of the well-recognized varieties of irrigators. Great care should be taken that no violence is done to the epithelium or to the soft structures.

Various solutions are discussed, and, in addition to the regulation treatment, he has occasionally found benefit from the following prescription :

Bichloride of mercury, gr. i;  
Ammonium chloride, gr. vi;  
Water, ℥xvi.

In his experience he has occasionally had good results with mild chloride of mercury dusted between the eyelids after the eyes have been cleansed. He has also used iodoform in the same way. Panas's solution is likewise recommended, according to the following formula :

Binioidide of mercury, 1 part;  
Absolute alcohol, 400 parts;  
Distilled water, reesterilized, 20,000 parts.

*THE DISINFECTION OF THE CONJUNCTIVAL CUL-DE-SAC.*

LAGRANGE (abstract in the *Annales d'Oculistique*, March, 1894, p. 237) thinks that, before opening the anterior chamber, it is absolutely necessary that the conjunctiva, and especially the superior cul-de-sac, should be thoroughly cleansed. In order to accomplish this, he has had the handle of a Desmarres elevator hollowed, to the upper part of which is attached an india-rubber tube, which is, in turn, in connection with a receiver containing an antiseptic liquid. In raising the receiver the liquid runs through the handle and through several holes at the outlet. He passes about a litre of sublimate solution (1 to 4000) into the eye which is to be operated upon. This irrigation is of great service in the treatment of purulent ophthalmia, where it not only dislodges the pus, but lessens the virulence of the cocci.

*OPHTHALMIA NEONATORUM.*

HIRAM WOODS (*Annals of Ophthalmology and Otology*, April, 1894) discusses certain causes of failure in the treatment of ophthalmia neonatorum, one of which he believes is rough handling of the affected eyes, especially by

ignorant attendants. He calls attention to the fact that nitrate of silver is often injudiciously and wrongly used, and is responsible for opacity of the cornea. According to Dr. Woods, the clinical condition demanding the non-use or discontinuance of silver is conjunctival purulency, unaccompanied by swelling or tension of the lids characteristic of infiltration, and without papillary swelling of the conjunctiva, or much of it, on the upper lid, and the deep-red color seen in the conjunctiva in severe cases. He insists upon the fact that mere purulency of the conjunctiva does not necessarily demand nitrate of silver, but that the appearances of the lids and conjunctiva must decide its use. He very properly protests against the practice of instilling cocaine to relieve the pain of ophthalmia neonatorum.

*IRIDECTOMY IN THE TREATMENT OF ULCERS AND ABSCESES OF THE CORNEA.*

BETTREMIUX (abstract in the *Annales d'Oculistique*, March, 1894) believes that there is no more effectual means of arresting the alarming progress of certain ulcers or abscesses of the cornea which have resisted every medical remedy, than iridectomy. He considers the dangers of panophthalmitis after the operation as insignificant. The anterior chamber in some cases must be again evacuated after the completion of the iridectomy.

*SKIN-GRAFTING AS A THERAPEUTIC AGENT IN MALIGNANT GROWTHS.*

DR. F. B. TIFFANY (*Ophthalmic Record*, April, 1894) recommends skin-grafting after the removal of malignant growths of the eyelids and orbits, the grafts being taken from a remote part of the body of the patient himself. His method is as follows: after thorough antiseptic preparation, both of the area of operation and of the portion of the body from which the graft is to be taken, the malignant growth is removed, its bed or seat is measured, and a corresponding measurement is outlined upon the arm or chest. The graft is then cut about one-third larger than the dimensions of the cavity to be filled. It is transferred, without handling, immediately to its new abode, where it is fixed in position by a few stitches of delicate silk. The parts are covered by antiseptic gauze and isinglass plaster; collodion and iodoform are never used. The parts are dressed daily, but the grafts are not specially examined for seven or eight days.

*INTRAOCULAR THERAPEUTICS: AN EXPERIMENTAL STUDY.*

HENRY M. CHASSEAUD (*Journal of Pathology and Bacteriology*, November, 1893, and the *Ophthalmic Review*, January, 1894) has performed a number of experiments to ascertain the value of intraocular injections. He concludes from his experiments:

1. That various fluids may be introduced with safety into the posterior chamber of the eye.

2. That chlorine-water is the only substance which fulfils the necessary conditions for a useful intraocular antiseptic. Its action is efficient, and it causes apparently no inflammatory reaction.

3. In regard to the other antiseptics tested, corrosive sublimate and carbolic acid, owing to their stable compounds with albumin and the inflammatory reaction which they produce, are not so useful as some others which are less active. Tincture of iodine, camphorated naphthol, hydronaphthol, eucalyptol, and other antiseptic oils are far too violent in their action and cause disorganization of the eye. Boric acid and iodoform are weak and non-irritant antiseptics. Oxycyanide of mercury and peroxide of hydrogen are just as good antiseptics as chlorine, but the former causes opacities in the vitreous and the latter seems to bleach the pigment of the eye. Creolin is a powerful irritant, and its antiseptic action is very doubtful. Pyoktanin does not act as an antiseptic in the vitreous; it gives rise to neuritis, with subsequent degeneration and atrophy of the optic nerve.

4. The idea of causing a localized adhesion of the retina to the choroid by inducing a moderate degree of inflammation in the former has not been very successful in practice. Slight degrees of retinitis can easily be produced; they are usually accompanied by a subretinal effusion. When this effusion becomes absorbed, adhesion between the retina and choroid never ensues in rabbits. In severe forms of retinitis caused by powerful irritants, we certainly get adhesion of the retina to the choroid, but with complete disorganization of the former, extending for a considerable distance from the point of injection.

5. In all forms of inflammation of the retina the nerve-cell layer is the first affected and suffers most. The external granule layer is the last to disappear. None of the seven layers are ever reproduced when once they have been destroyed.

6. Although the *staphylococcus pyogenes aureus* was injected into the vitreous over fifty times,

in no case did sympathetic inflammation affect the opposite eye, so long as the latter had not been the seat of a recent inflammation or had not been injured subsequently.

7. It must be borne in mind that all these experiments were performed on rabbits. In these animals the regeneration of the vitreous is wonderfully rapid, and persistent glaucoma, leading to disorganization of the eye, seldom, if ever, occurs. How far these results may be applicable to man it would be difficult to say.

*THE EFFECT OF SCOPOLAMINE ON THE EYE.*

LOBASSOW (*Revue Générale d'Ophthalmologie*, March, 1894), after a series of experiments on men and rabbits, comes to the following conclusions in regard to the action of scopolamine on the eye:

1. It dilates the pupil more quickly and powerfully than atropine, and paralyzes the accommodation, the effect being less lasting than that of atropine.

2. Its use causes no complications.

3. In spasm of the accommodation scopolamine acts more powerfully than atropine.

4. It is absorbed more quickly into the anterior chamber than atropine.

5. When applied locally or in subcutaneous injections, scopolamine favors the absorption of other substances into the anterior chamber.

6. Scopolamine increases the intraocular pressure in eyes predisposed to glaucoma.

7. The antiphlogistic effect of scopolamine is less than that of atropine.

8. In cases of idiosyncrasy, scopolamine is preferable to atropine.

*THE VALUE OF WEAK LENSES.*

The relation of weak lenses for the relief of asthenopia and other complaints is thus referred to in an editorial in the *Philadelphia Polyclinic*, May 5, 1894:

This is just now being discussed among the ophthalmologists, some of them claiming that they have a positive value in preventing eye-strain, while others believe that they only act by producing a mental impression.

The fact probably is that for many persons lenses of .50 D. spherical or less, or .25 D. cylindrical, produce no appreciable improvement of vision or freedom from strain. But the question of the necessity or value of lenses must always be influenced by the individuality of the patient; and there are persons to whom

the relief afforded by such lenses is positive and unmistakable, and it may be much greater than the relief that would be given to other persons by lenses of greater strength.

Hotz, of Chicago, has reported fifty cases in which such lenses were used after other remedies had failed to give relief. He found that the treatment was reported to have been successful in sixty per cent. of the cases. But one patient reported a negative result, and the others had not been heard from.

#### THE TREATMENT OF CHRONIC SUPPURATIVE OTITIS MEDIA.

BACON (*New York Eye and Ear Infirmary Reports*) says the usual treatment employed in the simple, uncomplicated cases is syringing the ear with warm water once or several times a day, according to the quantity and character of the discharge, and the instillation of the following drops:

R Zinci sulph., gr. ii to gr. iv;  
Acid boracic, gr. x;  
Aq. destil., ℥i. M.

Other drops used were those containing sulphate of copper or acetate of lead, which should be used when the discharge is not checked by sulphate of zinc.

When small granulations are present, these should be cauterized with nitrate of silver or chromic acid fused on the end of a probe, but when they are of large size or associated with caries, they should be thoroughly removed with Blake's snare or with curettes.

For small polypi or granulations the so-called alcohol treatment, consisting in the instillation of alcohol and boracic acid (20 grains to 1 fluidounce), is very successful in some instances, while in the treatment of granulations arising from carious walls he has met with marked success in the use of alcohol and iodoform (20 grains to 1 fluidounce). With some patients it will be necessary to dilute the alcohol one-half with water, as they otherwise complain of pain after the instillation of the drops. —*Philadelphia Polyclinic*, May 5, 1894.

#### TREATMENT OF URETHRAL CARUNCLES.

LEILL (*American Journal of Obstetrics*, April, 1894) treats urethral caruncles by the use of torsion or excision. The former operation presents the advantage of giving rise to a slight hemorrhage; the latter operation gives most assurance against a recurrence, and hemorrhage

is easily checked by a temporary tamponing of the urethral canal with a conical plug of styptic cotton.

#### LIGATION OF UTERINE ARTERIES FOR MYOMATA.

ROBINSON (*American Journal of Obstetrics*, April, 1894) has treated four cases of uterine myoma by ligation of the uterine arteries; neither the tubes nor ovaries were removed. This operation avoids the shock attendant upon hysterectomy; and since the ligature includes many nerves and cuts off communication with the automatic menstruation ganglion, immediate cessation of menstruation results. The operation is followed by steady atrophy.

#### PORRO'S OPERATION FOR OSTEOMALACIA, WITH A NEW AFTER-TREATMENT.

SEELIGMANN (*American Journal of Obstetrics*, April, 1894) treated a severe case of osteomalacia by Porro's operation; the stump of the uterus was dealt with extraperitoneally. The patient made an uninterrupted recovery. While the bones were still soft extension was applied. This was begun six days after the operation and continued for eight weeks. The patient was placed upon a water-bed and counter-traction applied from above. Weights were gradually increased until ten pounds were used. As a result of this the pain soon disappeared, the body became seven inches longer, and the configuration of the pelvis was favorably affected. The kyphoscoliosis dextrans disappeared. Thus, after seven years of bedridden life, with the most severe pains and deformities, the patient regained the power of walking, and at the time of reporting was capable of performing her household duties.

#### TREATMENT OF PUNCTURED WOUNDS OF THE BRAIN.

BERGER (*La Tribune Médicale*, March 29, 1894), discussing the subject of trephining for punctured wounds of the brain, states that the first treatment should be absolute rest, and that surgical intervention should only be practised when there are distinctly localizing symptoms.

VERNEUIL also declared in favor of expectation, and mentioned four cases of penetrating gunshot wounds without mortality, none having been subject to any surgical intervention. In

one case where an effort was made to search for the bullet, the latter was found some two or three inches away from the track taken by the probe.

POZZI reported the case of a girl who, fifteen days after a gunshot wound of the temporal region, complained of almost unbearable hemi-crania. There was a small wound from which pus was discharging. This wound was enlarged by the trephine and was drained, the patient recovering.

OLLIER saw a man who had received a bullet in the ear. He recovered with facial palsy and hemiplegia. Some months later he suffered from pain distinctly limited to the posterior parietal region. He was trephined, but nothing was found. Some months later he died, and at the autopsy the ball was found behind the pharynx.

#### TREATMENT OF INGUINAL ADENITIS.

BRAULT (*Lyon Medical*, No. 10, 1894) closes an elaborate paper upon the treatment of inguinal adenitis with the statement that incision should be the method of choice in cases of acute adenitis which complicate syphilis and gonorrhœa. Chancroidal buboes should be punctured, evacuated, and injected with nitrate-of-silver solution (five per cent.).

In acute tubercular adenitis all the infected glands should be excised at once.

#### COCAINE-POISONING.

RÉCLUS (*La Tribune Médicale*, March 29, 1894) reports a case of cocaine-poisoning which occurred in the practice of a colleague from urethral injection of the drug. The patient was seventy-two years old, and had retention of urine from enlarged prostate, for the relief of which hypogastric puncture was necessary. Repeated attempts at catheterization were necessary, and finally there was injected into the urethra five drachms of a five-per-cent. solution of cocaine. Scarcely was the injection made when the patient became extremely pale, was seized with trembling, and died in a few minutes.

Réclus, in commenting upon the case, placed the whole blame on the doctor who administered a toxic dose. He holds that solutions stronger than two per cent. should not be used, and the quantity employed should always be extremely limited.

BAZY stated that since it is impossible to inject five drachms into the urethra, a portion of

the solution must have passed into the bladder and been absorbed from this viscus, while S&E advanced the very plausible theory that the solution had probably been forced into false passages.

#### TREATMENT OF TUBERCULAR JOINTS BY PASSIVE HYPERÆMIA.

MIKULICZ (*Centralblatt f. Chirurgie*, No. 12, 1894) contributes in full a number of cases treated by Bier's method of passive congestion. In some the results were satisfactory, in others the patients were not improved or even grew worse. Therefore, the author of this paper holds that the passive hyperæmia treatment is, like all other measures, applicable only to certain patients. In some the virulence of the micro-organism infection is such as to overwhelm the tissues in spite of all help. In others the tissue-resistance is sufficiently strong to bring about cure without any help. As to the third class, where the destructive action is about equalled by the normal tissue-resistance, this method may, by increasing local nutrition, bring the disease to a favorable ending.

Since it is impossible to note beforehand what the effect of the treatment will be, Mikulicz holds that in each case the patient should be carefully observed for from eight to fourteen days from the beginning of the passive hyperæmia. If during this time the symptoms increase in severity, the treatment should be abandoned. If, however, the pain grows less, there is encouragement to go on. In one case, treated continuously for many weeks but not under careful medical surveillance, atrophy of the muscles of the arm occurred. Mikulicz now combines this method with iodoform injection.

(For details of Bier's method, see THERAPEUTIC GAZETTE, January 16, 1893.)

#### TREATMENT OF APPENDICITIS.

SWAIN (*Medico-Chirurgical Journal*, March, 1894) holds that, since about ninety per cent. of cases of appendicitis recover spontaneously, early operative interference in nearly every form of appendicitis is not justifiable. Cases of simple and plastic appendicitis are to be treated by rest in bed, moderate amount of liquid diet, purgatives, rectal injection if necessary, local application of leeches or fomentations, and hypodermics of morphine for the relief of pain. As soon as pus is present operation is indicated. This may be performed

during the first week, but is more commonly required during the second. When in doubt as to the presence of pus, there is usually no great harm in delaying operation. If, however, the symptoms are steadily growing worse and the pulse becoming rapid, operation is indicated.

Section, then, is called for in suppurative cases, in cases where there is good ground for suspecting deep suppuration, and also in the relapsing and rapidly-perforating cases. The best incision is the oblique one, placed at right angles to an imaginary line drawn from the right superior iliac spine to the umbilicus. This should be from two to four inches long, and should be placed about two or three inches internal to the iliac spine. In suppurative cases the incision should be placed over the seat of suppuration, since thus there is less risk of opening the peritoneal cavity. The appendix should be removed in suppurative cases only when this operation is readily effected without opening the general cavity. The risk of fæcal fistula is lessened by suturing the muscular and mucous walls of the stump of the appendix and then invaginating this into the cæcum and stitching the peritoneum over it.

HARSANT, in commenting on this paper, states that he has had two patients under observation, one of whom had four attacks, the other three. Both have now been free from trouble for several years, having apparently recovered without operation.

Low pointed out that post-mortem appearances offered insuperable objections to the theory that a foreign body caused the disease, and compared the appendix to the tonsil.

MITCHELL CLARKE held that the pulse and temperature were the best indices as to the need of operation. If, after first yielding to treatment, the pulse became more rapid and the temperature higher, this would indicate that operation is required. He reported the case of a boy in whom perforation into the general abdominal cavity had presumably taken place two days before he was seen, and whose abdomen contained free pus and gas. This boy recovered after operation by Bush, who simply opened and washed out the peritoneal cavity, and a few days later performed a second operation, removing the appendix.

NEWNHAM deprecated operative interference in all cases of appendicitis, and said that, although he had seen an enormous number of such cases, he had never known one to result fatally, nor any in which operation was necessary.

#### THE USE OF ICHTHYOL IN GYNÆCOLOGY.

POLACCO (abstracted in *American Journal of Obstetrics*, April, 1894) reports nine hundred and seventy-two gynæcological cases cured by himself and colleagues by the use of ichthyol, these including eczema of the vulva, pruritus, vaginitis, vaginal cicatrices, erosions of the cervix, ectropion, hypertrophy of cervix, multiple lacerations of cervix, deep lacerations of cervix, cervical endometritis, subinvolutions, and indeed all the known gynæcological affections.

Eczema and pruritus were cured almost at once. In vaginitis the results were most prompt and gratifying, the ichthyol being applied on tampons in antiseptic glycerin solutions. For endometritis ichthyol is used in ten- to twenty-per-cent. solution, and not only cures for the time, but prevents a return of the trouble. The drug was tried in some cases of metritis and parametritis; not more than  $11\frac{1}{2}$  grains were rubbed into the skin by means of a ten-per-cent. ointment, and it was also applied to the vagina by means of tampons impregnated with the glycerin solution. After three or four days of this treatment, combined with rest in bed and the mild use of saline purgatives, convalescence set in promptly.

The drug is absorbed, is comparatively cheap, since it is used in ten-per-cent. or at most twenty-per-cent. solution, does not permanently stain the clothing, has an odor which is easily disguised by volatile oils, and, unless used in conjunction with lanoline, never irritates the skin. Polacco concludes with the statement that ichthyol is the most potent analgesic known and adopted in gynæcological therapeutics of the day. It has a decided absorptive action upon exudations, manifested more rapidly when used in the early stage of the disease.

ALBERTOLETTI in the main agrees with the report just quoted, with the exception that he holds that ichthyol does not cause the absorption of exudation.

COLOMBINI states that cotton soaked in five- or ten-per-cent. solution of the sulph-ichthyolate of ammonia in glycerin causes speedy disappearance of acute vulvitis with painful erosions. In vaginitis tampons impregnated with this solution are equally efficient. In urethritis a five- to ten-per-cent. solution of ichthyol in water, when injected, caused prompt subsidence of symptoms. Cervical endometritis with ulcers was quickly cured in from six to eight treatments with tampons soaked in ten-per-cent. ichthyolate in glycerin, while the same solution, carried in by means of gauze wrapped around the body of a Playfair sound,

cured endometritis of the body of the uterus. Where the cervix was insufficiently dilated to allow of this procedure, intrauterine injections were made by means of a Bozeman double recurrent catheter.

#### ANTISEPTIC POWDER IN THE TREATMENT OF CANCER OF THE UTERUS.

LUTAUD insufflates the following powder daily, the os being exposed by means of a speculum :

R Acid. salicyl., gr. iv;  
Acid. boric., ℥i;  
Iodoform, ℥ii;  
Ess. eucalypt., q. s.

—*Der Frauenarzt*, Heft 3, January 9, 1894.

#### FORMULA FOR THE ADMINISTRATION OF IODIDE OF POTASSIUM.

FOURNIER suggests the following formula for the administration of iodide of potassium :

R Iodide of potassium, ℥vi;  
Anisette, ℥ii;  
Simple syrup, ad ℥vi.  
Dessertspoonful three times a day.

—*Der Frauenarzt*, Heft 3, January 9, 1894.

#### TREATMENT OF ACUTE METRITIS.

The following treatment of acute metritis is given in the *Revue Obstetricale et Gynécologique*, March, 1894: Absolute rest, laudanum fomentations upon the stomach, frequent hot irrigations with emollient and slightly aromatic liquids. The following represents an excellent formula :

R Chloral,  
Naphthol,  
Alcohol, of each, ℥iii;  
Water, ℥viii.

A tablespoonful of this mixture is added to a quart of hot water. After each injection there is placed in contact with the os a pledget of absorbent cotton soaked in the following mixture :

R Iodoform, ℥i;  
Chloral, ℥i;  
Glycerin, ℥iii.

In case of very severe pain, blisters applied to the abdominal surface give relief, or in milder cases these may be replaced by compresses sprinkled with turpentine or alcohol and covered with oiled silk. Scarification and leeches applied to the os are absolutely useless during the acute stage.

#### RADICAL OPERATION FOR LARGE HERNIA IN MALE CHILDREN.

SZUMAN (*Therapeutische Monatshefte*, Heft 3, 1894) holds that as soon as a congenital hernia shows signs of increasing operation should be undertaken, especially when the retention apparatus is not efficient. He operated on a child aged two years, with a scrotal tumor hanging to the knees. He dissected the neck of the hernial sac from the surrounding structures of the cord, freeing this sac to the external ring. A ligature was then placed as deeply as possible and the wound was tamponed with iodoform gauze. Two years later the child came under observation; the cure was found to be perfect.

A second child operated on was fourteen months old. Four and a half years later the cure was found to be permanent.

The third child was three months old when operated on. Eight years later the cure was perfect.

The fourth child had a colossal double scrotal hernia. In these operations free dissection of the neck of the hernia was extremely difficult. The dissection should always be begun high up, since here it is easier. When it cannot be completed in the lower part of the scrotum, as is often the case in congenital hernia, this portion is cut off and drained.

#### TREATMENT OF VENEREAL LYMPHADENITIS.

NOBLE (*Archiv für Dermatologie und Syphilis*, Bd. xxvii., Heft 1, 1894) reported to the Vienna Dermatological Society the results of his investigations into the method of treating venereal lymphadenitis proposed by Lang.

The treatment pursued is as follows: When a case was presented in which abscess-formation had taken place, this was punctured with the point of a bistoury and the contents evacuated by moderate pressure. The remaining cavity was washed out with a one-per-cent. solution of nitrate of silver driven in with some pressure. This solution was evacuated through the puncture and pressure bandages applied. In very large abscesses two puncture-points were made, more efficient drainage being thus secured.

This treatment of puncture, evacuation, and injection was continued two or three days, until there was no further secretion. This usually required but two injections. At first, after treatment there is a thick chocolate-colored exudate; finally only blood-stained serum escapes on puncture, and this, if it persistently accumulates, may often be left to absorption. When a case was presented in which abscess-formation

was not complete, showing uncertain fluctuation, the injections of nitrate of silver were forced not only into the cavity left by partial evacuation of the pus, but also in the surrounding infiltrated tissue. This causes, in two or three days, a painless softening of the diseased glands, or even brings about a more favorable result,—*i.e.*, prompt resolution of the inflammation. The treatment is contraindicated in the strumous form of buboes. These cases require radical operation. In seventy cases treated according to the method just detailed the average period of healing was ten days. In eight cases healing occurred in from three to five days. In eight cases cure was not accomplished for twenty-five to thirty days. In the great majority convalescence was complete in from five to ten days.

#### EXTERNAL APPLICATIONS OF SALICYLIC ACID.

MÜLLER (*Therap. Monats.*, March, 1894) claims that salicylic acid, when applied externally, exercises a powerful effect upon the economy, being especially efficacious in acute rheumatism when this is accompanied by skin-symptoms. Salicyl ointment he found particularly efficacious against the violent rheumatoid pains accompanying grip. In the case of idiosyncrasy against salicylic acid, he found the drug was taken perfectly when it was administered in wine of creosote.

#### PROSTATO-CYSTOTOMY.

BELFIELD (*Journal of the American Medical Association*, April 7, 1894) calls attention to the fact that the operation of Kraske for extirpation of the cancerous rectum has suggested to various surgeons a method of reaching important structures placed at the base of the bladder. Ullman removed a tuberculous seminal vesicle; Dittel proposed and Kuster executed the post-urethral excision of lateral masses of the enlarged prostate; Cabot suggested the extraction of ureteral calculi; and the present writer drained a suppurating prostatic utricle. Belfield then proceeds to call attention to what he terms posterior prostatocystotomy.

The anæsthetized patient is placed upon the left side, thighs flexed to a right angle, hips elevated eight inches or more, rectum empty, and bladder moderately distended with air; a broad grooved staff is introduced. From a point midway between the tip of the coccyx and the right tuber ischii a superficial incision

is carried forward, curving towards the raphe, which it reaches one and a half inches in front of the anus. Guided by a finger in the rectum and the staff, by blunt dissection the rectum is separated from the membranous urethra, prostate, and bladder-wall. The rectum being held out of the way by a retractor (it would be desirable here to ligate on each side the prostatic venous plexus, if unusually large), the point of a knife is made to enter the groove of the staff exactly in the median line half an inch above, and is carried downward to a point the same distance below the upper border of the prostate, dividing the trigone, the so-called "middle lobe" of the prostate, and the prostatic utricle, and terminating just above the orifices of the ejaculatory ducts. If required, the incision can be safely extended in the median line upward half an inch and downward through the thin commissure joining the lateral lobes of the prostate.

When the divided edges are drawn apart, the entire prostatic surface is accessible to eye and finger; the bladder can be drawn downward and the ureteral orifices exposed (on the cadaver). Complete suturing of the wound in bladder and prostate, while practicable, would probably be less desirable than partial suturing and drainage through the upper angle of the wound, which corresponds with the lowest point of the contracted bladder. This incision, he holds, gives perfect command of the entire prostate and base of the bladder and perfect drainage, hence reducing the dangers of infiltration to a minimum. It is also practicable in cases of contracted bladder in which the suprapubic method is not adapted. The author has used this cut for removing a calculus and lateral masses of the enlarged prostate.

Belfield also describes a new method for drainage of the bladder. A tenotome is made to enter the perineum with horizontal blade an inch or more in front of the anal margin, is passed between the prostate and rectum, and thrust into the bladder between the upper extremities of the prostatic lobes. A slender forceps is carried along the blade, the knife is removed, and the channel dilated by separation of the branches of the forceps for introduction of a drainage-tube. This incision opens and drains the prostatic utricle, an important factor in prostatocystitis from any cause.

#### CHRONIC RELAPSING APPENDICITIS.

BULL (*Medical Record*, vol. xlv., No. 13) records eighteen operations for relapsing appendicitis with one death. These operations

were done because of acute attacks so frequently repeated as to lead to the belief that there was a chronic appendicitis which had no tendency to disappear spontaneously or with the aid of medical measures. In most cases there was a tumor and a history of chronic invalidism. In about eighteen or twenty cases he advised against operation, because the attacks were at long or irregular intervals, and the interval was apparently one of good health, without tumor and without history of intestinal irregularity or pain.

Two of the operative cases were females. In seven pus was found on the operation, either in the appendix or close by in the false membrane, and the adhesions were firm and thick in the majority. One patient had been drained for an abscess only eighteen months previous to operation. The appendix was not found. Following recovery there were occasional attacks. On operation, the appendix was found, with lumen still patent and sharply curved, buried in a thick layer of false membrane lying on the surface of the cæcum.

Four hundred and fifty operations by various operators are tabulated, with eight deaths. Perhaps five or six per cent. would be nearer the truth.

#### SURGICAL USES OF SULPHO-NAPHTHOL.

BERRY (*New England Medical Monthly*, No. 145, vol. xiii.) strongly commends sulpho-naphthol in surgical practice. In the treatment of incised and lacerated wounds these lesions and the surrounding parts are thoroughly cleansed with a brush, and a one- or two-per-cent. solution of the drug is applied. Sutures are then employed, and the wound dressed with sterile gauze. For vaginal and uterine douches half to one drachm to the quart of water is the proper strength. Chronic cystitis is benefited by frequent irrigations, half a drachm to two quarts. This drug is not neutralized by albumin, does not injure instruments, does not irritate the hands, and is free from toxic properties. It is not as powerful an antiseptic as bichloride of mercury or carbolic acid.

#### TREATMENT OF ULCERATION OF THE RECTUM.

MATHEWS (*New England Medical Monthly*, No. 145, vol. xiii.) thus treats ulceration of the rectum. Benign ulcers absolutely require rest. This is best secured by a preliminary thorough purging and by confinement to bed combined with local applications. The diet should be liquid. The ulcer, if indolent, should be

touched with nitrate of silver, and after a healthy action is established, daily injection should be made into the rectum of,—

R Sweet almond oil, ℥i;  
Iodoform, gr. v;  
Nitrate of bismuth, ʒss.

Malignant ulceration should be excised at once. Tuberculous ulceration should be removed by the curette, if possible; if not, by the knife. Syphilitic ulceration is, when combined with stricture, about as incurable as cancer; hence resection is the only means of treatment.

#### ELÆOMYENCHYSIS, OR THE TREATMENT OF CHRONIC LOCAL SPASM BY INTRAMUSCULAR INJECTION AND CONGELATION OF OILS.

On the basis of cases treated by the method indicated in the title, CORNING (*New York Medical Journal*, April 14, 1894) writes in support of this treatment.

It is quite possible to inject melted, non-irritating oil into the living tissues, to allow it to congeal there, and to remain indefinitely without provoking the least inflammatory action. The vigor of muscular action may be sensibly diminished by curtailing the blood-supply. It follows from these two propositions that by injecting melted oil into a spastic muscle in sufficient quantity to interfere materially with the blood-flow and metabolism, then solidifying by means of cold, there would result interference with the nutrition and curtailment of the action of the muscle, the hardened oil acting as a species of intramuscular splint.

The case on which this method was tried suffered continuously for four months from clonic spasm confined to the left splenius muscle. The spasms were extremely violent and recurred frequently. Oil of theobroma was mixed with paraffin in such proportion that it remained solid at the temperature of the body. Eight hundred minims of this mixture were injected into the centre of the muscle. The fluid oil was promptly rendered solid by the aid of an ether spray and subsequently by the application of a small ice-bag over the muscle. The oil was so injected that it extended almost the entire length of the muscle. Some hours subsequently, as there was no inflammatory reaction, supplementary injections were made, forming fat segments, extending across the muscle at right angles to its axis. These injections were hardened as before. The clonic spasms ceased immediately, and there

remained only a certain rigidity, which became gradually less. There was no pain; the head could be held in normal position; the patient could sleep on the affected side without discomfort.

These injections should be made while the muscle is flexed, to allow of more even distribution and to secure splinting in this position. If necessary, ether may be administered to accomplish this where we are confronted with severe tonic spasm. The second point of importance is the distribution of the oil, which should be made regularly through the affected muscle; moderate massage greatly facilitates this part of the operation. A needle of large size, provided with an ample lumen, is necessary for the injection, and the syringe should hold at least half an ounce and be heated to 110° F. before filling.

COCAINE-POISONING.

KROGIUS (*Centralblatt f. Chir.*, No. 11, 1894) cites cases collected by Réclus, all due to colossal doses, and holds that, instead of injecting the drug just beneath the skin or in the substance of this, it should be driven deep down as near as possible to nerve-trunks. The injection should be made as the needle is being withdrawn. From 15 to 20 drops of a two-per-cent. solution are employed. After about ten minutes complete anæsthesia over a comparatively large area is produced. Thus, in the case of the fingers, for instance, by driving the injection in at the root, near the position of the supplying nerve-twigs, the entire finger to its deepest part becomes completely anæsthetized.

Reviews.

A TEXT-BOOK ON DISEASES OF THE EYE. By Henry D. Noyes, A.M., M.D. Second and revised edition. Illustrated by five chromo-lithographic plates, ten plates in black and colors, and two hundred and sixty-nine wood-engravings.  
New York: William Wood & Co., 1894.

Many good things in this world, like Massachusetts, need no eulogy, and, among text-books devoted to ophthalmology, Dr. Noyes's work easily takes high rank in this respect. We admired and commended the first edition, and are glad to welcome the second and reiterate this commendation.

The whole book has received thorough revision, many portions being practically rewritten. A notable feature is the author's familiarity with the literature of ophthalmol-

ogy, which has been utilized so well that the reader is quickly in possession of all that is valuable in the text-books, brochures, and papers bearing upon the eye. To quote from the preface, "the writer's judgment on new suggestions has been freely given on points where he has opinions," and it should be remarked that Dr. Noyes usually has opinions to which one may well pin his faith.

The departures from the paths of strict literary rectitude, to borrow a sentence from a well-known reviewer, are more frequent than agreeable, but they are readily forgiven in a book which, in other respects, is so good, so replete with sound teaching, clear judgment, and the fruits of wide experience.

ANOMALIES OF REFRACTION AND OF THE MUSCLES OF THE EYE. By Flavel B. Tiffany, M.D.  
Kansas City, Mo.: Hudson Kimberly Publishing Company, 1894.

The object of this book, according to the preface, is to present the subject of the anomalies of refraction and of the muscles of the eye "in as clear, brief, and concise a manner as possible, embracing all essentials, besides collaborating recent advancements not to be found in the existing books." The main portion of this task the author has accomplished fairly well, and many of the methods of examining for anomalies of the functions of the ocular muscles are more fully discussed in this volume than is customary. This is a commendable feature.

The book is profusely illustrated, and some of the cuts, especially those inserted in connection with the descriptions pertaining to reflection and refraction of light, answer an excellent purpose; others are dismal failures, and a goodly number are suitable in instrument-makers' catalogues, but have no particular value in a scientific treatise. The plates depicting the author's results in correcting strabismus are attractive pictures, but their introduction is an exhibition of questionable taste. The diagram of a persisting hyaloid artery is credited to Noyes and not to the author from whom Dr. Noyes borrowed it,—namely, the late Dr. Little.

Dr. Tiffany coins a new plural for apparatus,—"apparati;" perhaps there is authority for this word, but we cannot find it. He inveighs against "blurred print," and has carefully avoided criticism from this stand-point, since the type of his own book is excellent. A novel feature is the introduction of illustrated biographical sketches of Helmholtz, Donders, and Landolt.

LES AGENTS PHYSIQUES ET NATURELS: agents thermiques, électricité, modifications de la pression atmosphérique, climats et eaux minérales; cinquième partie des *Leçons de Thérapeutique*. Par le Dr. Georges Hayem, professeur à la Faculté de médecine de Paris, médecin à l'hôpital Saint-Antoine, membre de l'Académie de médecine.

We have reviewed in the pages of the THERAPEUTIC GAZETTE during the last two years the preceding volumes of this series by Professor Hayem, and have taken occasion each time to speak in a laudatory manner not only of the value of the books themselves, but of the good work which this indefatigable French author is capable of doing. The previous volumes, it will be remembered, dealt, the first with drugs, and the second with the application of drugs to disease. The present volume is devoted to the consideration of remedial measures other than drugs, and takes up exhaustively the use of heat, hydrotherapy, electricity, atmospheric pressure, aerotherapy, climates, and mineral waters, forming with its predecessors a complete monograph upon the therapeutic resources of a modern well-educated physician. We wish that it were possible to have these books translated and published in English, for they combine in a concise form a large amount of information which should be possessed by us all. The price of the volume in the French language is but \$2.50.

### LONDON.

(From our Special Correspondent.)

It requires a good deal of experience with any new drug before it can be said to come into popular favor, and the pioneers who experiment with such new substances generally find it somewhat difficult to get others to help them in making the necessary observations. Being personally much interested in pharmacological matters, I try to acquaint myself with most such experiments or their results. Two such drugs have recently attracted some attention from their vaunted use in ophthalmic medicine, and the accompanying notes, which I have been able to put together as the result for the most part of personal observation, may be considered as perhaps worthy of perusal.

First, with regard to "tropa-cocaine," introduced by Chadbourne about two years ago, and used first by Schweigger and others in German clinics. This was said to be a most satisfactory local anæsthetic for even the major ophthalmic operations, possessing the advan-

tage over cocaine that it exercised no cycloplegic effects, and could be used in those cases in which a rise of tension was to be feared. Owing to the difficulty in obtaining the drug, as well as to its great cost, tropa-cocaine did not get a very extended trial in this country, until a little while ago attention was again drawn to it in a paper read before the Ophthalmological Society. The author had used tropa-cocaine in the form either of solution or of ophthalmic tabloids, and gave records of the satisfactory performance of most of the ordinary operations under the anæsthesia induced by its means. After this paper had been read, tropa-cocaine was stocked by one of the leading drug-houses, thus enabling a much more extended trial to be made of its efficacy as an anæsthetic, and I have personally seen it used in a great variety of operations. For the removal of foreign bodies it leaves nothing to be desired, as these can be seen so much more readily against a background of iris, and the patient is not troubled with the inconvenience of a paralyzed accommodation for some hours after. The pain accompanying iridectomy or cataract extraction is also satisfactorily abolished, while absorption into the system is not followed by unpleasant consequences. Besides all this, tropa-cocaine has been very successfully employed as a dilute solution in cases of painful inflammation of the conjunctiva, abolishing the excessive irritability without interfering with the vascular supply. When it becomes better known and cheaper it cannot fail to come into very general use.

In a recent paper by Dr. Casey A. Wood, of Chicago, I notice the curious statement, towards the end of the work, that "tropa-cocaine has, so far as my experiments went, no cycloplegic advantages over cocaine, while its mydriatic action seemed to me to be less than that of cocaine" (Pan-American Congress, 1893). I cannot help thinking that Dr. Wood must have confounded tropa-cocaine with some other drug, or been supplied with the wrong material, for, as I have pointed out above, the pure substance has neither a mydriatic nor a cycloplegic effect. It is only the pure synthetic drug that is suitable for ophthalmic work.

With regard to the second drug—scopolamine—about which I was going to speak, I find that this is already somewhat known in America, and has been mentioned recently in the pages of the GAZETTE. It became first known to me in December, 1890, when a specimen was submitted to me by Messrs. Burroughs and Wellcome. At that time I made a number of physiological experiments with this suggested

substitute for atropine, none of which, however, were published. As it is now highly improbable that they ever will be published in concrete form, I take this opportunity of giving the chief conclusions I was able to draw from my experiments. First, when tested on my own eye, it proved a good mydriatic even when used in very dilute solutions (1 to 1000). When complete mydriasis had been produced it lasted for about a day and a half, after which accommodation became again possible, the pupil becoming normal in the course of the third day. Its action was not at all unpleasant and produced no uncomfortable effect upon the throat. Its general action when tested on animals seemed considerably less than that of corresponding doses of atropine. In order to produce the well-known vagus effect of atropine with scopolamine, greatly larger doses were necessary; in fact, I see from the blood-pressure tracings which I then took, and to which I have just referred, that the inhibitory action of the vagus on the heart was not completely paralyzed by the doses I employed.

Passing now from physiological experiments, which agree, I believe, in results with those made and published recently by other observers, I would describe the clinical use, as observed in this city, of the hydrobromate, which has been placed on the market by Merck. My own experience has been mainly directed to its use in the estimation of refractive errors. For this purpose a 1 to 250 solution has seemed most suitable. The instillations have in each case been made by the surgeon, and absolutely no untoward effects have been observed. Three instillations, at intervals of about half an hour, using each time about two drops from a Liebreich drop-bottle, have in almost every case sufficed to completely paralyze accommodation and to produce full mydriasis, which, if left to itself, has passed off after at most three days. Generally, however, the patient is given a disk of eserine (Wyeth) to insert into the conjunctival sac on the morning following, and this has had a material effect in shortening the period of inconvenience.

The solution of a strength of 1 to 500 has been used also in a variety of conditions in which atropine is usually employed, and those who have used it speak highly of its efficacy in some cases of phlyctenular keratitis and iritis. It has not been known to raise intraocular tension, but perhaps experience has not been sufficiently extensive to warrant the statement that such an effect may not follow its use in some cases. All tell me, and my own experience tallies with that of others, that scopolamine

is quite as efficacious as atropine, and that its action is free from the unpleasant by-effects produced by the latter drug.

I hear very varied opinions as to the enjoyability or otherwise of the recent Medical Congress at Rome. The general opinion seems to be, among compatriots most of whom visited the Eternal City for the first time, that the outside attractions were too great to allow one to give a due amount of attention to the more serious sectional work.

#### THE TREATMENT OF TONSILLITIS.

To the Editors of the THERAPEUTIC GAZETTE:

DEAR SIRs:—I desire to tender my professional brethren a treatment (both *local* and *constitutional*) for follicular tonsillitis, which has proved very satisfactory in my hands for several years.

If seen *very early* and no complications, Dr. Sajous's "*abortive treatment*" with ammoniated tincture of guaiac (a teaspoonful every two hours in sweet milk) will often (not always) be found quite satisfactory. If, however, called to see the patient later, which is generally the case, give calomel, 10 grains; soda bicarb., 20 grains; M. ft. chart. no. iii. One every three hours, floating on a teaspoonful of water, and no liquid after for twenty minutes. These powders to be followed by a teaspoonful or two of castor oil with 10 to 15 drops of turpentine every hour (for first twelve hours), excepting the hour of the powders. Gargle and swallow a teaspoonful of a saturated solution of c. p. sulphate of sodium. After the powders are all used and worked off with the castor oil and turpentine, alternate the solution of sulphite of sodium with the following chloride syrup, both as gargle and systemic remedy:

R Pot. chlorat, ʒi;  
Ammon. mur., ʒi;  
Tinct. ferri mur., ʒiv;  
Glycerini, ʒiiss;  
Syr. limonis, ʒii. M.  
Dose.—Teaspoonful.

If for a child under three years reduce dose of all the remedies and dispense with the gargling, but give no liquids for ten or fifteen minutes after giving the liquid medicine.

This treatment will prove most satisfactory in every case, and comports well with the late theory that it is really "a germ disease" and *infectious*.

C. G. SLAGLE, M.D.,  
*Professor Diseases of Children, Minneapolis*  
*College of Physicians and Surgeons.*

### MORE HEROISM IN COUNTRY SURGERY.

A PAPER READ BEFORE THE WEST BRANCH MEDICAL SOCIETY OF PENNSYLVANIA, JANUARY 30, 1894.

BY SPENCER M. FREE, M.D., DUBOIS, PA.

IT has been intimated to me that my subject is somewhat obscure. I therefore pause a moment to define more fully its meaning. More surgical heroism on the part of those practising surgery in country towns and rural districts is needed. These men should be

more fearless in the use of surgical measures after they have diagnosed a case; or in cases of doubtful diagnosis, if these measures will enable them to ascertain the malady, they should not hesitate to use them.

That such hesitation exists, that we countrymen follow too often and too long an expectant plan of treatment when radical measures promptly applied are better, will not be denied by any of us, I think.

This being true, we need to be more heroic and fearless in the exercise of these great powers. "Delay is dangerous," "He who hesitates is lost," are axioms not more true

anywhere than in the life of a surgeon. This paper is presented in the hope that it will strengthen the weak hearts and feeble knees among us. To observe and analyze failures is oftentimes better for both doctors and patients than to contemplate successes.

It is not my intention, had I the ability, to present an article of fine literary finish, nor do I wish to pose as an instructor and to lay down dogmatically certain rules of action. It is my hope that discussion may be provoked, which will make of us better men, better surgeons.

Some years ago I was hastily summoned to the bedside of a girl who had for several days been suffering with diphtheria, to find that she had developed laryngitis, presumably diphtheritic. Emesis proved of no avail. The symptoms indicated a rapidly fatal issue. There was but one hope,—tracheotomy. Intubation was then unknown. In college it had been impressed upon me by our professor of surgery to never operate with any other than a stiff-backed knife. Having with me only my pocket-case of folding knives, I hastily went to my office, two squares away, for proper instruments. When I returned the patient was dead. It is possible that the girl would not have recovered had the operation been done. It was probably diphtheritic laryngitis, and very few of these cases get well whether operated upon or not. This is a very good salve for an irritated conscience, and is applied entirely too frequently with soothing effect; but I have never been able to get away from the thought that I am responsible for not having given the girl that last chance for her life. If I had possessed the courage to depart from my teachings, and had opened the trachea with any knife at hand, I would at any rate have kept my patient from choking to death, and the result might have been different.

Nor are these days of hesitation gone by. Only a few months ago I was called in consultation with a recent graduate to see a case of diphtheritic laryngitis. The child was cyanotic and unconscious. In answer to my question why he had not operated, the doctor replied that he did not have a tracheotomy-tube. Not knowing the nature of the case, I had not brought intubation set, tracheotomy-tube, or proper instruments for operation, but I had a pocket-case. We operated at once without anæsthetic, and tied back the sides of the wound and trachea with silk. The operation did not prevent death, but it prolonged life for twenty-nine hours and allowed an easy end. What the result might have been had intubation or tracheotomy been done twenty-four or forty-

eight hours sooner we cannot say. Certain it is, however, that the child had not the best chance possible.

In 1884 I had under my care a man suffering with some intestinal obstruction or what seemed to be such. He did not have fecal vomiting, but had many other symptoms, which led me to make the diagnosis of probable intestinal obstruction. For several days an expectant plan of treatment was carried out without benefit, and finally the man died. No post-mortem was allowed, and I therefore cannot give you a correct diagnosis of the case. Had I possessed a sufficient amount of heroism I should have opened his abdomen. I could have probably discovered the trouble, relieved it, and saved the life of my patient. It is true that the diagnosis was not certain, that the operation was a dangerous one, and that the community might have accused me of killing the patient. These are all truths, but there is also another truth, that the patient is dead without my having exhausted the possibilities of my profession for his relief. More heroism might have saved his life.

Less than two years ago, in a neighboring town, a most estimable Christian woman, the wife of a prominent citizen, was ill with some abdominal trouble. Day after day her physicians saw her fail in strength. That the trouble was abdominal was clear, that it was appendicitis was probable, though not certain. The expectant plan was followed until she died. The post-mortem proved it to be a case of suppurative appendicitis, which could have been relieved by operation. The patient would most likely have recovered from the operation, and again blessed home and town with her beautiful life full of good deeds.

In June, 1892, a locomotive fireman was suddenly seized with a severe illness while on duty. He was taken to his hotel and medical aid summoned. He got worse, and a consultation of physicians was held. The diagnosis of appendicitis was agreed upon, and the expectant plan of treatment was followed. After some weeks the man had recovered sufficiently to be about his room, when he was again attacked with the disease. The same plan of treatment was followed with a like result. This time he got even better than before, was able to walk about, and was preparing to return to work when he was seized with a third attack. The same physicians attended him in each illness. During this third attack I was invited to give an opinion of the case. I suggested that it was one of recurrent suppurative appendicitis, and should be operated upon at once. The ex-

pectant plan had twice been successful, and the attending physicians were not heroic enough to adopt the surgical proceeding. The former plan of expectancy was followed for two days, when the patient was suddenly seized with severe abdominal pains and went into collapse. Every effort was made to stimulate him and to bring him out of this condition, but he failed to respond to treatment. He sank rapidly, became unconscious, and in a very brief time passed into that "country, from whose bourn no traveller returns." A post-mortem was not allowed, so that I cannot state positively that it was a case of suppurative appendicitis. This was the diagnosis of the physicians, and is probably correct. Operation during the first or second attack or at the beginning of the third would most likely have been successful and have saved the life of the patient. The courage of the attendants was not equal to the occasion. Another opportunity to benefit humanity and to show the ability of our art to overcome the dire circumstances of our environment was lost. Another life was sacrificed because of a lack of heroism in country surgery.

In 1888, Mr. L., forty-five years of age, was lifting to his utmost strength, when he was seized with pain in the right inguinal region and became faint. He was assisted to a house near by and given some whiskey and water. He made an examination as soon as possible, and found that his truss had broken and allowed his hernia to come down. He replaced it, as he had done frequently. He said that it went back easily. He was removed to his home, and took a large dose of Epsom salts, as was his custom after having trouble with his hernia. Pain became severe, and I was called. The bowels had moved three times during the day. The pain was partially relieved by hypodermic injection of sulphate of morphine, and some tablets of the same were left to be used if the pain returned. There was no evidence of hernia present. So far as I could discover, it had been successfully reduced. On visiting him the next day, I found that he had used more of the morphine than should be necessary to relieve ordinary pain, and was yet not entirely free from it. Another examination could discover no hernia. Mild cathartics were ordered, and the morphine continued as needed, with hot fomentations over the abdomen. The next day (the third) he was in about the same condition, and I asked for consultation. The consultant lived twenty miles away. He arranged to come the following day, the fourth of Mr. L.'s illness. A wreck on the railroad prevented his coming. This I learned on the fifth day. Several en-

emas of warm soapsuds had been given on the fourth day and night. They came away, but did not bring fecal matter. The fifth day the patient was free of pain, had no vomiting, was taking a good amount of nourishment, and was feeling quite well. Under the circumstances the family concluded to avoid the expense of a consultant at that time. The sixth, seventh, and eighth days were about the same as the fifth, above described. On the eighth day I again asked for consultation. There had been no passage of fecal matter, though mild cathartics were used and enemas given occasionally. There were no urgent symptoms, the patient was bright and cheerful and was eating well; yet I felt uneasy. His facial expression seemed to me to point towards some abdominal trouble, and, as the slang phrase puts it, "I felt in my bones" that something was wrong within the man. The family reluctantly yielded to my request for consultation, thinking it was unnecessary, as he was "getting along so well." I had not allowed him to get out of bed nor to sit up in it. Had cautioned him to be very careful even in turning and moving about in the bed. On this (the eighth) day I particularly tried to impress this upon him. The consultant answered that he would come the following day, being the ninth of Mr. L.'s illness. We prepared ourselves for operation, and went to the patient's house, to find that he had died half an hour before our arrival. The history given was as follows: He had felt better than usual, and when some friends had come in he concluded to get up and sit with them for a while. He got out of bed, walked about fifteen feet into the room, when he fell to the floor. He was picked up, put back into bed, and expired almost immediately. The whole time occupied was about twenty minutes. A post-mortem was requested. Permission was given, and we did it at once. We found that the inner abdominal ring was divided into two parts of unequal size by a cord of tissue about one-eighth of an inch in diameter. In the smaller opening was a fold of the intestine tightly constricted and gangrenous. A tear existed on the inner side and intestinal contents were in the abdominal cavity. The tumor on the outer side was about as large as a chestnut and could not be felt through the abdominal wall. The family exacted a faithful promise that we would take nothing from the body; and though we explained to them the peculiarity of the case and how valuable the specimen would be to us, they would not permit us to have it, and it was buried with the body. The man probably ruptured the gut by getting out of bed and

walking across the floor, and died of collapse resulting therefrom. The case was in many respects a very peculiar one. The symptoms were somewhat misleading. Perhaps the majority of practitioners would have pursued the same course that I did; but had my courage been sufficient to have done an operation early for diagnostic purposes, how easily a life would have been saved!

A case of only recent occurrence is the following:

Mr. S. had been suffering for several months with some suppurative disease of the upper leg. Diagnosis of osteomyelitis of the femur was made, and advice given to amputate the leg at once. The attending surgeons did not agree to this, however, and continued medical treatment and local washes for six weeks longer. By the end of this time the patient was much worse. On cutting into the leg, the bone was found to be almost completely destroyed, and amputation had to be done about three inches below the acetabulum. The operator remarked at the time that the operation had been too long delayed and that the case would end fatally. This prediction proved correct, and the man to-day sleeps beneath the sod as a result of too little heroism on the part of country surgeons.

I have presented thus far a series of cases having the same mournful termination, and you may well ask the question, Does the heroic use of surgical measures show better things? I answer, Yes. Worse results could not occur than the expectant treatment has produced in the cases above named. Time will not permit the recital of many cases. The few I present cannot be as fully reported as they deserve, but they will be sufficient to show what can be accomplished by the timely use of ordinary intelligence combined with ordinary surgical skill.

The first case which I present is that of Mr. S. He had a double fracture of the femur. Union took place at one point of fracture but not at the other. Operation was suggested from time to time, but was as often deferred. Finally it was consented to. The leg was opened up. The ends of the ununited bone were brought into full view and sawed off. They were put into proper apposition and pinned by a long steel pin. The leg was put up in plaster of Paris. Perfect union was attained, and the man has been earning a living for more than four years as fireman and engineer of a stationary engine. His leg is an inch and a half shorter than the uninjured one, but it is just as strong, and the man walks without much of a limp.

In July, 1802, Mr. C., a train agent, had a

difficulty with some passengers. A fight ensued, during which he received a kick in the abdomen. It caused him a little shock at the time, some vomiting, and a good deal of pain. He vomited blood and passed blood per rectum the next day. He was in bed a few days, and, feeling better, he left his hotel and rode seventy miles on a train to a more congenial stopping-place. He was able to walk about, though he had constant pain in the abdomen at the point where he had been kicked. His bowels were constipated. One morning, when straining at stool, he was seized with violent abdominal pain. He fell from the closet-seat to the floor in collapse, and remained thus for several hours, notwithstanding the combined efforts of a number of physicians. I saw him about ten hours after the attack occurred. His temperature and pulse were subnormal and his general condition bad. It seemed clear that there was some abdominal trouble, but not clear just what it was. The expectant plan of treatment was agreed on, with the suggestion that if he became worse a laparotomy should be done or, at least, an exploratory incision made. There was not much change in his condition during the next twenty-four hours, but there was no improvement. During the third day he had one slight and one severe attack of collapse. I insisted that laparotomy must be done and an effort be made to save the man's life, which, under the existing circumstances, was fast ebbing away. The operation was performed on the fourth day, about seventy-six hours after the first attack of collapse. We found at the point of injury a diseased gut adherent to the abdominal wall. It was already considerably constricted, and no doubt would have been almost, if not entirely, occluded as the adhesion became more firm. There was present a beginning suppurative peritonitis. The adhesion was carefully destroyed, the gut antiseptically treated, the abdominal cavity thoroughly washed out with an antiseptic solution, and the wound closed and dressed in the usual antiseptic manner. The man recovered and has been at work ever since. I think that this case clearly shows the value of surgical interference for diagnostic purposes. Had we delayed operation even another day, I think that a post-mortem diagnosis would have been made. The result is all the more gratifying when we remember that this man was the sole support of a sister and a widowed mother.

Another case of great interest to me (and had I time to present the history in full you would agree that truth is stranger than fiction) is the following:

Miss G. had been ill for several months with what had been diagnosed Bright's disease, liver trouble, bilious fever, typhoid fever, by as many physicians. The fifth doctor "didn't know what was the matter." O Diogenes, search no further; here is an honest man!

Finally she fell into the hands of Dr. T. R. Williams, who diagnosed some abdominal tumor. I was invited to see her, and though we could clearly make out a tumor of considerable size and variable consistency, and though her condition indicated a suppurative process somewhere in her economy, we could not make a positive diagnosis. She was bedridden, emaciated, weak, discouraged, and about ready physically and mentally to die.

There was one hope which we offered her, and which she accepted; that hope was laparotomy. Before she was etherized her pulse was over 120 and her temperature nearly 103° F. As she lay before us under the anæsthetic, ready for the knife, the same thought was probably in each mind that was in my own: "Is this homicide?" My answer was quick and clear. It was, "No: it is the last plan my art offers to save this life." Here there was no time or place to hesitate. Quickly was the abdomen opened, and almost immediately lay before us a tumor as large as a cocoanut. One part of it was suppurating, from which we removed an ounce and a half of pus. Adhesions were numerous and firm, and great difficulty was experienced in detaching it. At this trying moment the patient ceased to breathe, her radial pulse failed, and the end seemed at hand. "Stop operating," said one; "she's dying." "I guess that's right," said another. "No, sir," said the operator. "Put that strychnine and whiskey into her and keep her breathing. Go and tell her friends she is dying, but we must have this tumor out; she's not dead." She rallied; the tumor yielded to force and was removed. The patient recovered, and to-day walks the streets of her native town, a monument to the glorious art of surgery as practised with ordinary but determined skill by country doctors.

I shall conclude this paper—which has already been far too lengthy, I fear—by the recital of a case which could profitably occupy the entire time allotted to me, and which shows how wonderful indeed are the resources of surgery, if only we have courage to obtain and use them. I shall compress the history into as few words as possible.

In the spring of 1890 I was called by an old practitioner and a man of surgical reputation to see with him a farmer's wife past sixty-three years of age. Four days before this the patient

was straining at stool, when she was suddenly seized with pain in the right inguinal region.

The doctor was sent for and saw her each day. The pain was relieved without difficulty. There was not much vomiting. The bowels had not moved, however, though many cathartics had been given, and the patient was not in good condition.

I ventured the opinion that it was a case of strangulated inguinal hernia, and ought to be operated upon at once. With this Dr. H. could not agree. I suggested that a third physician (Dr. W.) be called. He arrived the following day, the fifth from the time the woman became ill. Dr. W. concurred in my diagnosis of strangulated hernia. We operated, and found the diagnosis correct. The gut looked well except at the two points of constriction. We concluded that it was safe to return it, and did so. The case progressed nicely for a week, when fecal matter began to pass out at the point of operation through a small hole which had not healed by first intention, thus establishing an artificial anus. The patient passed the contents of the bowels in part per rectal anus and in part per artificial anus. This became a great annoyance and life was a burden. She was told that she could probably be cured by intestinal resection. She accepted the opportunity offered, took the chances, and was operated upon. We found on opening the abdominal cavity that the gut had sloughed at the two points of constriction. Fortunately, it had attached itself to the inner abdominal surface at the point of first operation. We found on examination that the only safe thing was to resect the intestine. We removed four inches of it, stitched the ends together, and closed and dressed the wound antiseptically. The patient made an excellent recovery, and is to-day, at sixty-seven years of age, healthier than before the operation. She is also cured of her hernia, at least she has not had an attack since. Dr. H., though a surgeon of thirty years' experience, would have followed an expectant plan of treatment until the patient died, rather than have been heroic enough to cut for diagnostic purposes.

The case also teaches another lesson. The woman had passed sixty-three years of her life; she was operated upon at her farm-house home; she was on a bed, and the operator on his knees beside it; she had only such care and nursing as her daughters could give her; many discouraging circumstances surrounded the case throughout; but the final outcome was eminently satisfactory.

Hence we learn that if we do not become

faint-hearted and weak-kneed, but act heroically, promptly, and determinedly, we have within our power an art that will accomplish, even in rural districts, things that seem like impossibilities.

I trust that this recital of a few of the many cases that have occurred in my short career in the practice of our noble calling has interested you sufficiently to bring forth accounts of similar experiences, and after studying together our failures and our successes, may we turn homeward more heroic men and better prepared to properly serve those unfortunates of our race who will in future require our surgical care.

### THE TREATMENT OF PHTHISIS BY TUBERCULIN.

REPORT OF MY OWN CASE, WITH OBSERVATIONS OF ITS USE IN OTHER CASES.

BY LLEWELLYN PHELPS BARBOUR, M.D.,  
MONTEAGLE, TENN.,

Formerly Lecturer on Physical Diagnosis in the Medical Department of the University of the South; Member of the Tri-State Medical Society of Georgia, Alabama, and Tennessee; of the State Medical Association of Tennessee, etc.

THE premature surrender of tuberculin by Professor Koch; the unfounded enthusiasm that followed; the use of the remedy by the inexpert and careless; its employment by even the expert in advanced cases, contrary to the advice of its originator,—all this is familiar history. The inevitable reaction that followed this unseemly and unscientific eagerness was as emphatic in unfounded and indiscriminating condemnation *in toto* of tuberculin.

I was an interested reader of the reports following the first use of this remedy. Much of this literature was valueless, coming as it did from men inexact and unveracious. But I found that the testimony of reliable men, who severely sifted and tested their conclusions, agreed in that tuberculin did exert a specific effect upon tubercular tissue; and I reasoned that, as a result of this specific action, under proper conditions, we could hope to obtain a beneficial effect. The majority of these men reported an occasional cure. The number of these reported cures, together with the conditions surrounding the trial, was sufficient to prove that tuberculin was *the cause* of the cure. If in but one case of phthisis, after severely accurate, deliberate, rigorous therapeutic trial, tuberculin stood as the curative agent, given the same conditions, it would cure other cases.

Enough was accomplished in the first year of its use to give me faith that, when we had learned to select our cases properly and to use the proper dosage, tuberculin would prove a valuable addition to the therapeutics of phthisis. Later, reports from men who were using much smaller doses than at first given, and who were combining other approved methods of treatment with the tuberculin, increased my faith. Still later, upon finding that I had phthisis, I proved my faith by placing myself under this treatment.

The results of the use of tuberculin in my own case and in other cases under my direct observation I report in the following paper.

A persistent, hacking cough in June, 1892, first led me to suspect that I had phthisis. This cough lasted six or eight weeks. During the next ten months the only evidence of such trouble was occasional pain in the chest. My general health remained good until May, 1893; then began a gradual loss of strength. In April, 1893, the cough returned, with slight expectoration, and this continued to increase, until I began treatment with tuberculin. I took a great deal of cod-liver oil and creosote at intervals during the year, and in large doses. Though I continued the creosote steadily from the 1st of June to the 1st of August, taking from 45 to 60 minims much of the time, throughout June and July I lost ground rapidly.

During the first week of August my temperature went to 100° F. every day, and once or twice beyond that point. On August 10 it registered 100.4° F. in the afternoon and 96° F. at night, the highest and lowest I ever noticed. The cough was not severe, but frequent, raising about one-half drachm of mucopurulent sputum each time. There were two or three coughing spells each night. Sleep was restless from a condition of general malaise. A walk of two hundred rods tired me. My appetite continued fairly good, and this, with the cod-liver oil, doubtless kept my weight from failing as rapidly as it otherwise would have done. For years it has averaged one hundred and four pounds in summer and one hundred and ten pounds in winter; on August 9 it was an even hundred.

On August 10 a careful examination of my chest revealed the following: Slight dulness on percussion over the upper lobe of each side; right side, anteriorly, broncho-vesicular murmur throughout the entire area of upper and middle lobes and upper part of lower lobe. This changed quite abruptly to the normal vesicular murmur at the lower edge of the fifth rib; throughout

this area the inspiratory murmur was shortened; in the upper and middle lobes there was considerable crepitation and numerous moist râles; on the left side, anteriorly, the same physical signs were found, but not quite so intense; the extent was about the same; posteriorly, on the right side, a small area of broncho-vesicular murmur in the apex; on the left side the area of abnormal murmur extended over all the upper lobe and the upper third of the lower lobe; about the middle of the scapular region was a spot an inch and a half in diameter in which there was no respiration whatever; this was probably due to collapse, though at the time it was supposed to be an area of consolidation.

An examination of the larynx revealed considerable tubercular deposit and a small ulcer. At the base of the tongue at the left side was a tubercular ulcer one-eighth of an inch in diameter.

The microscope revealed numerous bacilli.

On August 13, 1893, I began the tuberculin treatment at the Winyah Sanitarium, Asheville, N. C. The first dose was  $\frac{1}{10}$  milligramme, the second  $\frac{1}{8}$  milligramme. I received three injections of tuberculin each week for the next twenty-seven weeks. The increase was at first by  $\frac{1}{10}$  milligramme, then by  $\frac{1}{8}$ , then by 1,  $2\frac{1}{2}$ , and finally by 5 milligrammes. The injections were given at 10 A.M. and at 8 P.M. A careful examination of the chest was made for evidence of a local reaction. This occurred in my case twenty-two times, an average of once for every increase of dose. Sometimes, however, I would react two or three times under the same dose, and at other times would have two or three increases without any reaction. The same amount was always given me twice at least, and then increased if there had been no reaction. The dose was always repeated until it had been taken twice in succession without a reaction. If a given dose produced systemic effects, even though slight, it was at once reduced; this occurred once. On October 9 I received 2 milligrammes for the first time. My temperature went a little higher on that day than it had done during the preceding three weeks. For two days I had a tired, worn-out feeling, and expectorated very freely. This is the only time in the entire course of treatment that I experienced any depressing effect from the tuberculin. At one other time it became necessary to reduce the dose because of too violent local reaction. This was on December 13, when I received 6 milligrammes. No râles or crepitation had been heard in my chest for two months previous to

this dose, but after it these adventitious sounds were quite plentiful, and there was decided increase in the bronchial character of the respiratory sound. Expectoration was increased for a day or two, but there was no increase of temperature or other systemic symptoms. A slightly increased expectoration was not rare on the morning following an injection. The last dose I received was 25 milligrammes on March 5; no reaction.

My improvement was slow, but continuous throughout. At the end of the first month I had gained five pounds in weight; two of these were lost in the next two weeks. After that time the gain was steady until December 25, when I weighed one hundred and twenty-three pounds, as much as I ever weighed in my life. Since that date my weight has varied from one hundred and twenty-two to one hundred and twenty-five pounds. The cough and expectoration began to lessen after the first month of treatment. By October 1 I was coughing almost none, and there was not more than a teaspoonful of sputum a day. Since the middle of December there has never been more than a trace of sputum and no cough. The number of bacilli had materially lessened at the end of three months' treatment. After the fifth month I was not often able to find any bacilli, and the few I did find were degenerated forms.

The temperature gradually lessened to nearly normal; for several months the daily range has been from 97° to 99° F.

The improvement in the physical signs kept pace with the improvement in other respects. The râles and crepitation had disappeared after ten weeks; the broncho-vesicular breathing gradually softened, until now respiration is normal, except in the upper lobe of the left lung, where it is much improved. There is no dulness on percussion. The spot on the left scapular region has been restored to a normal condition. The ulcer at the base of the tongue healed very quickly; the laryngeal ulcer proved quite obstinate, but was entirely well by the middle of January.

While under treatment myself I was given opportunity to examine other patients as often as I wished, and was thus helped to reach conclusions as to the value of tuberculin and as to its action.

That this remedy, which produced an intense congestion of the tubercular area when given in the large doses used at its first introduction, should produce a stimulant effect when given in small doses seemed to me a warranted, logical assumption; and it was demonstrated to

me that there is a point where the doses are sufficiently large to maintain this slight stimulant effect, and yet so small as to produce no systemic effects. An audible evidence of this stimulation is a "local reaction." For instance, upon examining a patient, I found broncho-vesicular respiration throughout the upper lobe, with a few râles at the apex. Eight or ten hours after an injection of tuberculin I found a decided emphasis in the bronchial character of the respiration, an increase in the number of râles, and some crepitation. At another time in the progress of this case there was, before taking the tuberculin, only a slight variation from the normal murmur, with no râles or crepitation; ten hours later there was a pronounced broncho-vesicular murmur. Several times I have examined patients and found no change apparent in the lungs, and yet they would tell me there had been some increase in the amount of expectoration. It is easily conceivable that the stimulation may be so slight as to be imperceptible to the ear. My observations have convinced me that this continued gentle stimulation assists in healing ulcerated areas and in producing absorption of tubercular deposits.

I found the same improvement in the lungs of my fellow-patients as reported in my own case: cessation of crepitation, of râles, and lessening of the bronchial character of the respiratory sound. In the larynx, also, my improvement was paralleled in the history of other cases, and here the demonstration was to the eyes. An increased redness of the tubercular area could be seen during a reaction, and as time passed a gradual disappearance of the deposit and a healthier appearance of the ulcer were noted, until its complete cure; and in some cases the tubercular laryngitis healed fully when the lung condition was such as to make ultimate recovery hopeless. As to whether the small doses have any direct effect in the destruction of bacilli I am not decided. However this result is accomplished, I found the same lessening of number and degeneration of form, with final disappearance, in other cases as in my own.

I would not create the impression that I consider these results as due to the tuberculin alone. The patients cited have had the help of a good climate, have been treated with the pneumatic cabinet, and have been watched over carefully as to diet and exercise. I give full credit to all these influences. The pneumatic cabinet was, I am sure, of help to me and to others in dilating collapsed air-cells and in strengthening the respiratory muscles. The judicious man-

agement of the patient in regard to rest and exercise is, I believe, of greater importance than many of the profession realize. Exercise too long continued or too violent wrecks the chances of many patients. They require constant oversight to keep them from overdoing, and at the same time to persuade them to take sufficient exercise. As to myself, I think I approximated a perfect course. When I was at the worst I did almost nothing avoidable, but made rest my prime object. As soon as I was able, I did some walking or riding every day, increasing the amount as my strength increased, but stopping before I was in the least fatigued, and always carefully avoiding violent heart-action.

The influence of a good climate in overcoming phthisis is unquestioned, though the amount of credit it deserves in my case is problematical. For nine years I have lived on the Cumberland Plateau, in Tennessee, at about the same altitude and latitude as Asheville, and there I contracted the disease.

In common with every one who has any knowledge of phthisio-therapy, I have always been keenly alive to the value of good nutrition: it is a *sine qua non* in recovery from consumption. Since I first suspected such trouble, I have been careful to keep my digestion good and to use nutritious food; so my diet was chiefly of meat, eggs, and milk before, as after, I came to the Sanitarium. To neglect nutrition would be like a general going into battle neglecting powder and ball. Nothing that will make for the better can be neglected in the fight against consumption. I realize to the full what can be accomplished by good climate, good diet, and careful attention to rest and exercise; yet I know that when all care and wisdom have been exercised in these directions, statistics still show a woful fatality, and that these statistics have been decidedly improved by the use of tuberculin, combined with all these other means.\* And I further know that in my own case all these precautions and methods, employed, as I think, with intelligence born of careful investigation, were insufficient and were failing me. With my own senses I have observed the effect of the tuberculin in many patients; I have seen results obtained, *as a rule*, that are exceptional under any other treatment. In view of all this, I can but credit tuberculin with an important part in my own recovery and in the gratifying results I saw obtained in the large majority of my fellow-patients.

# TRACTION IN THE TREATMENT OF HIP-JOINT DISEASE.

BY JAMES K. YOUNG, M.D.,

Instructor in Orthopædic Surgery, University of Pennsylvania;  
Attending Surgeon, Orthopædic Department,  
University Hospital, etc.

SO much confusion has existed in regard to the principles of the treatment of chronic joint-affectations, especially the hip-joint, that it is gratifying and encouraging to observe the growing tendency to recognize certain principles as essential and to disregard or exclude others as secondary or unimportant. The principles of joint therapeutics were three,—immobilization, fixation, and traction.

Much importance was formerly attached to immobilization, but as this was found to be impracticable, the modern term fixation has been adopted by all, and the only difference of opinion of late has been in regard to the use, value, and method of the application of traction.

The true value of traction is not admitted by all, but every year witnesses its more general adoption, until its establishment as the first principle of correct orthopædic practice appears to be only a matter of time.

In a recent brochure, Stillman\* has reviewed, entirely without prejudice, the principles involved in the different methods employed by the leading authorities.

This may be taken as representing the general trend of methods among leading surgeons; and while it will be found that almost all use bed traction in some form during recumbency, when apparatus is applied permitting locomotion, five employ fixation without traction against fourteen who employ traction apparatus of some kind.

It is gratifying to note that the so-called physiological treatment of Hutchinson, of crutches and a high shoe upon the healthy limb, without any form of apparatus, and the so-called expectant plan of treatment of Knight, or no treatment at all, except during the exacerbations, are becoming obsolete. I say are becoming obsolete, because I thought these methods had been abandoned until a week ago, when my attention was called to a little patient treated by the former method. As Gibney says, "Whenever one can feel assured that he has a genuine case of chronic articular ostitis of the hip, science demands, humanity demands, that the so-called expectant methods should form no part of the

treatment. This rule admits of few exceptions."

The advantages of the traction methods are threefold,—

1. A diminished number of abscesses.
2. A shorter time for cure.
3. A perfect recovery.

1. A comparison of the methods employed beyond the seas with our own shows a much larger number of abscesses in the transatlantic as compared with the cisatlantic statistics.

This has been particularly referred to by Bradford and Lovett† and the writer elsewhere,‡ and it is unnecessary here to refer to it in detail.

2. If traction methods are continuously employed from the beginning to the end of treatment, a shorter time will be required, both on account of the earlier relief, the rarer relapses, and the diminished frequency of abscess deformity and other complications.

3. With continuous traction methods perfect recovery may be more confidently expected in a large number of cases for the same reasons. To be sure, different types of disease must be recognized, and this the writer has granted on several occasions,§ and has even gone so far as to classify the different types of disease met with in the hip-joint.|| But granting all this, the most favorable type will be conducted to the most favorable termination more quickly and with a more perfect result by the use of traction methods than by any other method. This is well exhibited in some cases already reported by the writer,¶ in which perfect motion, a fraction of an inch of shortening, and no deformity—ideal results—were exhibited.

The question of how to accomplish continuous traction can best be answered by informing you as to my own methods and by the description of methods which may be employed anywhere by any one. The plan of treatment employed in private cases and cases well under control consists of four parts: (1) bed traction, (2) the use of a traction splint and crutches, (3) the traction splint alone, (4) and the traction splint as a protective splint.

1. Bed traction may be employed, as in the ordinary Buck surgeon's adhesive plaster method for fracture of the femur, with which all practitioners are familiar, or, what I prefer, the Sayre extension, made of heavy adhesive plaster (made

lacing and crossing these ends over each other up the limb, and is secured with a muslin bandage. (Fig. 2.) By means of a short leather strap from three to six pounds' extension is made. Bed extension is only employed during acute exacerbation, and only for a limited period,—for one or two weeks.

2. The traction splint is adjusted, as described in all systematic works, by securing the waistband, buckling the perineal straps, attaching the straps of the foot-piece to the leg extension, and by means of the ratchet and key making extension until a comfortable amount of traction has been made. Motion should be restricted at the pelvic joint, and the apparatus must be applied and traction made in the direction of the axis of deformity. If the case has been treated thoroughly and efficiently from the commencement of the attack, deformity will be avoided, or, if an acute attack occurs, with pain, flexion and adduction of the limb, the patient should be at once placed in the recumbent position until it has subsided. The foot-piece should extend below the shoe on the diseased side sufficient to allow the foot to swing clear, and a high shoe should be worn on the sound limb, sufficiently high to allow the brace to swing clear (about three inches) when the child walks on crutches. The brace-crutch treatment is employed until all evidence

of acute disease has disappeared, or for from six to eight months.

3. At the end of this period the crutches are discarded, and a shoe about one and a half inches high is worn on the sound side to equalize the length of the limbs, and the child walks on the traction splint. (Fig. 3.)

FIG. 3.

Traction splint applied as in third part of author's plan  
of treatment.

4. After a variable period, ranging from one to two years, the high shoe is altogether discarded and the foot-piece is fitted close to the shoe of the affected side, the perineal straps are loosened, but still worn, and the patient continues the use of the traction splint as a protective brace only. This should be worn for at least a year after the cure has been established, to prevent relapse. Throughout the entire period general constitutional treatment should be employed, varying the drugs with the seasons and the caprice of the patient, and local counter-irritation should be used during all but the last stage, during which period massage will be found most serviceable. The whole treatment will extend over a period of from two to four years.

For general use by practitioners who are unable to have special apparatus manufactured to suit each case, a simple and efficient plan of traction would be of interest. This may readily be accomplished by means of a modified plaster cast.

The adhesive plaster strips are first applied. The entire limb on the affected side should be thoroughly padded with cotton batting, secured by a roller from the malleoli to the waist. This is best applied in the vertical position, with the patient standing on a chair and the limb swinging clear, or, better, resting

on an inverted basin, with the buttocks close to the edge of the bed and an assistant making firm traction. Before completing the cast, six buckles are incorporated in the dressing, two front and back, each over the spinous processes,

FIG. 4.

Author's modified plaster cast traction splint.

and one about three inches above each malleolus. These may be attached to strips of tin, leather, or webbing. The cast may be strength-

FIG. 5.

Author's modified traction splint applied.

ened by strips of tin, or wood bandage. It is then trimmed out around the perineum, and may be made removable by splitting down

the front, binding, and adding eyelet-hooks. Two perineal strips are attached to the buckles above and the extension strips are secured below, and by these means any amount of extension may be made. (Fig. 4.)

A cheap wooden patten on the sound foot (worth about forty cents) and a pair of crutches (worth from twenty-five cents to two dollars) complete an outfit with which hip-joint disease may be treated scientifically. (Fig. 5.)

No provision is made for deformity, as any change in the position of the limb is to be considered as indicative of the commencement of an exacerbation, and demands immediate recumbent bed extension until it has been overcome.

If, by means of this simple apparatus, the simplicity, principle, and importance of traction methods in the treatment of joint-disease become more generally recognized, the object for which this article was written will have been accomplished.

#### TRIKRESOL AS AN ANTISEPTIC FOR COLLYRIA.

BY E. A. DE SCHWEINITZ, PH.D.,  
Biochemic Laboratory, Department of Agriculture; Professor of  
Chemistry, Columbian Medical College, Washington, D.C.

THE value of the cresols, or of preparations of the same substances, as antiseptics, was first pointed out in 1889 by Fränkel,\* and subsequently Hueppe,† Hammer,‡ Paradies,§ Gruber,|| and others have emphasized their importance. More recently attention has been called to trikresol, which is better and less injurious than carbolic acid, by Liebreich,¶ Charteris,\*\* and Dr. Reed, of the Army Medical Museum of Washington, D.C. It is considered three times as efficient as carbolic acid.

The frequent contamination of collyria with harmful bacteria has been pointed out by Francke and others, and again emphasized by recent papers which I have prepared in

\*\* *Lancet*, 1894.

conjunction with Dr. G. de Schweinitz.\* Up to the present time the chemical sterilization of such solutions has been rather unsatisfactory, owing to the strength of the carbolic acid, corrosive sublimate, or mercury cyanide which must be used to insure disinfection; hence it occurred to me that trikresol might be useful.

Trikresol is a mixture of the ortho-, meta-, and para-methyl phenols, or ortho-, meta-, and para-kresols, and contains the hydroxyl group, which seems to be a characteristic of antiseptics and germicides. Its irritating action is restrained, although its disinfecting properties are not interfered with, by the presence of the methyl group in the molecule.

To test its value in the desired connection, I first made up a solution of trikresol with ordinary Potomac River water (1 to 500 and 1 to 1000). After forty-eight hours the Potomac water (1 to 500) gave no growth when inoculated in peptonized beef-broth; the 1 to 1000 solution gave no growth on the fourth day. A solution of 1 to 1000 with distilled water, inoculated in peptonized beef-broth, agar, and potato, yielded no growth after thirty minutes.

The effect of this trikresol solution upon the

eye was tested by dropping it into a rabbit's eye, and also by injecting  $\frac{1}{10}$  cubic centimetre into the anterior chamber. Dropping the solution into the eye produced not the slightest irritation. The injection of the 1 to 500 solution caused moderate reddening above the point of puncture, which disappeared without any general inflammation in two days. Injection of a 1 to 1000 solution produced very moderate hyperæmia of the blood-vessels in the ciliary region, just above the point of injection; not more, however, than might be expected from simple puncture of the cornea, and this disappeared within twelve hours. These observations were made with the naked eye, without the use of the ophthalmoscope.

It seemed, therefore, that the 1 to 1000 solution might be used for the preparation of the collyria. The three drugs most liable to contamination in a short time are cocaine, atropine, and eserine, and of these solutions were made in the following strengths: hydrochlorate of cocaine, four per cent.; eserine, one grain to the ounce; atropine, four grains to the ounce. Trikresol water was used as the solvent. These solutions were placed in ounce glass-stoppered bottles, no particular care being used to protect them from dust, and they were allowed to stand for a week in a loosely-closed closet in the laboratory. At the end of this time the bottles were opened without flaming their mouths, and cultures made from the solutions, but no growth appeared upon the media. The bottles were then allowed to stand uncorked for a week in a closet which stood just in front of the window. This closet was opened four or five times a day, and no care was taken to prevent contamination with dust. At the end of this time the collyria were still clear, and cultures from them showed no growth. The next day happened to be a breezy one, and as the door of the closet was open, the dust from the street had free access to the open bottles. Though the solutions themselves still appeared unaffected, cultures from the eserine and cocaine yielded a slight growth, but the atropine remained sterile. This test was much more severe than any to which the collyria, preserved even with the slightest care, would be submitted.

The pipettes belonging to these several solutions were rinsed out twice with the 1 to 1000 solution of trikresol, and then inoculations made by rinsing them with sterilized beef-broth. No growth resulted. After rinsing them again with the trikresol solution, they were allowed to lie in open, wide-mouthed bottles for some time, and subsequently used to

\* THERAPEUTIC GAZETTE, September 15, 1893, and Transactions of College of Physicians, Philadelphia, March, 1894.

transfer the collyria to the culture-tubes. Again no growth was produced.

The effect of the solution, in this instance made from eserine, was tried on a rabbit's eye without causing any inflammation.

Trikresol water (1 to 1000) dropped into my own conjunctival cul-de-sac failed to cause the slightest burning or the least inflammation.

I would suggest, therefore, that it would be advantageous in making up collyria to use trikresol water (1 to 1000). In addition to the usual solutions kept in the ordinary treatment case, there should also be a small vial of trikresol water for rinsing the pipettes after use. By this method I think that the fungus and bacterial growths often found in collyria might be prevented, as well as any eye-complications resulting from the use of a contaminated solution. These collyria have now been prepared for three months, and no growth, fungous or otherwise, is apparent in any of them, and no growth is yielded by cultures.

In many cases the trikresol solution 1 to 500 could be used more advantageously than the 1 to 1000. When dropped into my own eyes the 1 to 500 solution produced no burning sensation whatever. As trikresol has been found to be such a good antiseptic and is fatal to the pyogenes aureus, it would doubtless prove very useful in general ophthalmological practice.

*THE NON-OPERATIVE METHODS OF  
TREATING ANAL FISSURE OR  
IRRITABLE ULCER OF  
THE RECTUM.*

READ BEFORE THE AMERICAN MEDICAL ASSOCIATION,  
JUNE 7, 1894.

BY LEWIS H. ADLER, JR., M.D.,  
Professor of Diseases of the Rectum, Philadelphia Polyclinic  
and College for Graduates in Medicine; Surgeon to the  
Charity Hospital, etc., Philadelphia, Pa.

WHEN anal fissure is of recent origin and not associated with much spasm of the sphincter muscles, there is a fair prospect of cure without operative procedure.

This statement is made advisedly and in the face of a criticism, published in *Mathew's Medical Quarterly*,\* of the writer's brochure ("Fissure of the Anus and Fistula in Ano" †), in which the following statement is made: "It is a pity that this admirable little work wastes so much time in discussing the palliative (?) treatment of the disease [fissure]."

"An affection so simple in its etiology and

pathology, and that can be so quickly and radically cured by divulsion of the sphincters, it seems a great loss of time to talk about applying ointments, when it is a recognized fact that not one case in ten is ever benefited by their use."

I do not doubt but that the reviewer quoted honestly expressed himself in the statements made; and, furthermore, that the opinion given—that not one case in ten is ever benefited by other means than operative measures—is based upon personal experience. But I must be pardoned for dissenting from the same views, as my experience, while not an extensive one, is ample to justify a more conservative treatment of many of these cases.

I am well aware that the operative treatment of fissure is a simple procedure, and that the disease is quickly cured by its execution; but I am likewise conscious of the fact that many persons object strenuously to any operation.

No matter how trifling its import be to the surgeon, an operation to the patient is something which is dreaded, and it behooves the practitioner to remember that the majority of persons are unwilling to submit to operation until they are personally convinced that such a course is the ultimatum.

It is my purpose in presenting this paper to indicate how over seventy-five per cent. of the cases of fissure of the anus which have come under my observation, both in hospital and private practice, have been cured by non-operative measures. No less an authority than Allingham ‡ states that the curability of this lesion does not depend upon the length of time during which it has existed, but rather upon the pathological changes it has wrought. He also adds that he has cured fissures of months' standing by means of local applications, where the ulcers were uncomplicated with polypi or hemorrhoids, and where there was not any marked spasm or thickening of the sphincters.

It is essential to the success of the treatment of fissure by local applications that rigid cleanliness of the parts be maintained; for this purpose the anus and the adjacent portions of the body should be carefully sponged night and morning and after each stool with tepid water. It is also highly important that attention be given to the condition of the patient's bowels. Regularity of habit should be established, and the evacuations rendered semi-fluid, as figured or hard stools materially aggravate the symptoms.

\* January, 1894, vol. i., No. 1, p. 185.

† "Physician's Leisure Library Series," 1892. Geo. S. Davis, Publisher, Detroit, Mich.

‡ "Diseases of the Rectum," fifth edition, 1888, p. 215.

To accomplish these purposes, enemata or mild aperients should be employed, and the diet must be regulated, the use of bland and unirritating food being enjoined.

All drastic purges should be avoided, as they are more or less irritating to the extremity of the rectum. To establish a daily evacuation of the bowels and to render the movement as painless as possible, I am in the habit of ordering an enema of warm water, or one of rich flaxseed tea, say from half a pint to a pint, to be administered every evening, preference being given to the night-time, as then the patient can assume the recumbent posture, which, combined with the rest, affords the most relief from subsequent pain.

If the first enemata should prove ineffective, it should be repeated in half an hour. In order to relieve the pain and spasm of the sphincters attending the evacuation, it is well to use a suppository about half an hour before the injection is employed, consisting of,—

R Ext. belladonnæ, gr.  $\frac{1}{2}$  ad  $\frac{1}{2}$ ;  
Ext. opii aq., gr.  $\frac{1}{4}$  ad  $\frac{1}{2}$ ;  
Ol. theobromæ, gr. x.  
Misce et fiat suppositoria i.

Or an ointment of conium may be used, as recommended by Mr. Harrison Cripps.\*

R Ext. conii,  $\mathfrak{z}$ ii;  
Olei ricini,  $\mathfrak{z}$ iii;  
Ung. lanolini, q. s. ad  $\mathfrak{z}$ ii.

A small quantity of this ointment should be smeared on the part five minutes before expecting a motion and again after the bowels have been moved.

In applying any of the various local remedies to an anal fissure it is necessary first to expose the ulcer to view, which can be done by means of the operator's or his assistant's fingers, and to anæsthetize its surface with a four-per-cent. solution of the hydrochlorate of cocaine, well brushed in with a camel's-hair pencil or with a piece of cotton attached to a probe. The application of the cocaine may have to be repeated once or twice, at intervals of three or four minutes, in order to obtain the desired anæsthetic effect. If any ointment has been used about the fissure, the anus should be subjected to a hot-water douche before using the cocaine, as this drug will not exert its anæsthetic influence on a greasy surface.†

Among the different remedies that have been used in the local treatment of fissure of the anus may be mentioned the following: Nitrate of silver, acid nitrate of mercury, fuming nitric acid, carbolic acid, sulphate of copper, the actual cautery, and chloral hydrate.

Of these topical applications, the nitrate of silver is the best. Its effects are various: it lessens or entirely calms the nervous irritation which is so important a factor in producing spasmodic contraction of the sphincters; it coats and shields the raw and exposed mucous surface by forming an insoluble albuminate of silver; it destroys the hard and callous edges of the ulcer, and tends to remove the diseased and morbid action of the parts.

The form in which I usually employ this salt is in solution (from 10 to 30 grains to the ounce). The stick caustic may be also used.

To accomplish the best results, the solution should be used once in twenty-four or forty-eight hours, according to circumstances. It may be applied by means of cotton attached to a silver probe or to a piece of wood.

The application is made by separating the margins of the anal orifice with the thumb and index finger of the left hand, and introducing into the anus the probe charged with the solution. The argentic nitrate is to be applied to the fissure only; a few drops are all that is required. If thorough local anæsthesia has been induced by the use of cocaine, the application of the silver salt produces little, if any, suffering, for, by the time the anæsthetic has lost its effect, the otherwise acute pain of the nitrate of silver will have passed away.

After each application the part should be smeared well with an ointment of iodoform (30 grains to the ounce). The odor of that drug may be disguised by the addition of a few drops of attar of roses. Iodol may be used instead and in the same way, but I prefer the iodoform, owing to its anæsthetic qualities.

After the ulcer has been touched once or twice with the silver solution, the effect will be, in the cases that are benefited by this treatment, a considerable mitigation of the pain from which the patient suffered when at the closet and afterwards, and the sore will present a healthy, granulating appearance, and will slowly contract in size.

Unless the fissure be complicated with some other affection in children and in young persons, anal fissure is almost always curable by adopting the mode of treatment laid down.

Some authorities speak highly of the use of the acid nitrate of mercury, fuming nitric acid, carbolic acid, the actual cautery, etc., but in

\* "Diseases of the Rectum and Anus," second edition, London, 1890, p. 189.

† W. P. Agnew, M.D., "Diagnosis and Treatment of Hemorrhoids," etc., second edition, San Francisco, Cal., 1891, p. 91.

my opinion their employment is attended with more suffering than follows the use of the nitrate of silver. Furthermore, the application of these remedies is not so certain to effect a cure, so that I rarely resort to their use.

The daily introduction of a full-sized bougie, made of wax or tallow, will sometimes act beneficially in cases of fissure by stretching the sphincter and producing such an amount of irritation as will set up a healing process in the ulcer. An application of cocaine or of belladonna ointment should be made to the part previously to their employment.

In the treatment of anal fissure, Allingham strongly advocates the local use of the following ointment:

R Hydrarg. subchlor., gr. iv;  
Pulv. opii, gr. ii;  
Ext. belladonnæ, gr. ii;  
Ung. sambuci, ʒi. M.  
Sig.—To be applied frequently.

He states that he has had many cures with this ointment alone. Another excellent ointment recommended by this same authority is,—

R Plumb. acetatis, gr. x;  
Zinci oxidi, gr. x;  
Pulv. calaminæ, gr. xx;  
Adipis benzoïnât., ʒss. M.

An ointment of the oxide of mercury (30 grains to the ounce) has cured many cases.

In conclusion, I would emphasize the fact that in many cases anal fissure, when uncomplicated with some other rectal affection, is curable by means of non-operative methods of treatment.

1610 ARCH STREET.

#### THE TREATMENT OF ERYSIPELAS.

By J. M. ANDERS, M.D., PH.D.,

Professor of Medicine, Medico-Chirurgical College, of Philadelphia.

THE subject of the treatment of erysipelas falls naturally into three subdivisions: 1, dietetic treatment; 2, constitutional; 3, local.

1. *Dietetic.*—The proper attention to the diet is of first importance. It must be generous and composed of highly nutritious articles. If the temperature be high, liquid forms of nourishment alone should be administered, giving them in small quantities at definite, short intervals. Rectal alimentation should be resorted to if the stomach rejects a suitable dietary. Based on considerable practical experi-

ence, I have been convinced of the fact that liberal feeding is of greater service to the patient than any recognized form of medicinal treatment.

This method, pursued from the onset of the attack, will not only serve to render the course of the disease more favorable than if less energetically fed, but will also lessen the liability to the more frequent complications.

Erysipelas is, as shown elsewhere, a self-limited disease, in uncomplicated cases, when occurring between twenty and fifty years of age. In such the necessity for vigorous alimentation is not greater than in other acute infectious diseases having a comparatively short course. Relapses occur in eleven per cent. of the cases, and lack of attention to the patient's diet during the primary attack does unquestionably increase the frequency of their occurrence.

When the disease occurs in persons over fifty years, when complications arise, and when the vital processes have been lowered on account of previous chronic disease, such as chronic nephritis, chronic phthisis, organic disease of the heart, etc., the course is much more protracted. The fact that these chronic affections also increase the receptivity of the human organism to the specific germ of erysipelas, as well as the mortality-rate, must be recollected. Now, it is in the classes of cases just mentioned, or in those in which the duration is prolonged, that correct alimentation is of paramount advantage, fortifying the vital functions, thus abridging the course of the affection.

And since death is directly ascribable to exhaustion, with few exceptions in these instances, the life of the patient is thus frequently savable. Again, when nourishment is exhibited judiciously, stimulants are required but rarely.

There can be no question but that the typhoid state of the system met with in this and other acute infectious diseases is often attributable indirectly to hyponutrition. I fear we have come to rely too much upon the local and constitutional agents in the management of this disease, to the neglect of proper dietetic means, a more potent factor.

2. *Constitutional.*—When, however, despite appropriate diet, the pulse becomes feeble, the first sound of the heart indistinct, and the tongue dry, undoubted indications for the use of stimulants are present and must be heeded. When needful they should be given with a comparatively free hand. Stimulation is most apt to be required in aged and enfeebled patients suffering from the disease. I frequently

order to be taken from sixteen to twenty ounces of whiskey or brandy daily in divided portions.

The promptness with which strychnine acts leads me to place it among stimulating agents in the first rank in these cases. In marked gastric irritability, champagne is to be preferred. Numerous antiseptic remedies have been recommended, but they have not been, up to the present, available in doses large enough to be of decided advantage. In view of the fact, however, that the disease is known to be caused by the streptococcus of Fehleisen, further trial of antiseptic agents should be made. I have been for a decade or over exhibiting to erysipelas cases bichloride of mercury in moderate-sized doses throughout the febrile stage, and have found some degree of amelioration of the symptoms as the result.

The tincture of chloride of iron, first used extensively by English authorities, was formerly regarded by most clinicians as a truly specific remedy; perhaps the majority of authorities no longer accept this dictum. The profession, as the result of abundant experience, are, for the most part, of the belief that other preparations of iron are at least equally efficacious. While engaged recently in making a collective investigation into the etiology, complications, mortality-rate, etc., of erysipelas, many facts relating to the treatment of this disease were met with and noted. They were taken from the records of several hospitals in Philadelphia. In this connection reference will be made to points bearing upon the internal treatment alone, the local treatment being discussed subsequently. Through the kind assistance of Dr. Morris Booth Miller, important data were obtained from the records of the Pennsylvania Hospital; the cases had been under the care of Drs. Lewis, Da Costa, Longstreth, Meigs, and others. From the year 1872 to 1876 inclusive there occurred in this institution seventy-four cases of erysipelas which were treated by the use of the tincture of the chloride of iron alone (the average quantity being one drachm daily in divided doses), with three deaths, or a mortality of four per cent. Of these, thirty-six were so-called idiopathic cases and thirty-eight traumatic, those proving fatal being idiopathic. The ages of those who died were sixty-six, forty-nine, and twenty years respectively; the immediate cause of death was noted as exhaustion in the first two instances. No complications were recorded in the first instance, but extensive bed-sores developed in the third, while the second fatal case (aged forty-nine) developed œdema of the glottis.

Twelve of the cases reported from the Johns Hopkins Hospital were treated with iron and stimulants, the results being about the same as in those reported from the Pennsylvania Hospital.

From 1877 to 1892 inclusive some of the erysipelas cases in the Pennsylvania Hospital were treated by other methods, which will be spoken of presently. In sixty-six cases, however, during the latter period iron alone was administered. A single death occurred, and in this instance the fatal termination was due to œdema of the glottis. Forty-eight cases were classed as idiopathic and eighteen as traumatic. It is quite probable that during the period in which this series of instances occurred, iron was depended upon only in the milder forms of the complaint, for the following reasons: In the first place, quinine was exhibited with the iron in very many instances, and here the percentage of deaths was, as shown hereafter, quite high. In explanation of this fact, we find that quinine was combined with iron in all of the severer types of the affection. That quinine is to be justly held responsible for the increased mortality (which occurred in the cases in which it formed a part of the internal treatment) is altogether unlikely. The value of iron is more reliably shown by the first group of seventy-four cases (above mentioned) than by the second, consisting of eighty-four cases, since in the first group *all* of the cases, during the period from 1872 to 1876 inclusive, were treated by this remedy singly, while the death-rate was only four per cent. These are favorable results when the status of the vital powers of hospital patients in general is kept in remembrance.

I have shown elsewhere\* that the general average mortality-rate in hospitals is 6.57 per cent.; in private practice, 4.16 per cent. Not a few of the seventy-four cases treated by iron alone manifested complications, and since some of these modify unfavorably the prognosis, they should be mentioned here.

In thirteen there were abscesses (though it has been shown that this complication does not augment the death-rate to any extent), in two delirium tremens occurred, in two general articular rheumatism, and in one scurvy. As pointed out in a previous paper, pre-existing chronic affections render the outlook gloomy, but we find that one of the cases developed in the course of chronic pulmonary tuberculosis,

---

\* "The Complicating Conditions, Associated Diseases, and Mortality-Rate in Erysipelas" (*International Medical Magazine*, October, 1893).

another in a hemiplegic, both of which, however, recovered under iron.

The number of cases treated by iron and quinine in combination, from 1877 to 1892 inclusive, was eighty-one; and of these, fifty-five were idiopathic and twenty-six traumatic. The average daily dose of quinine administered was from 12 to 16 grains. Ten cases proved fatal,—a mortality of 12.3 per cent. The cause of death in two instances was acute Bright's disease, in two delirium tremens, one pyæmia, one exhaustion during fourth relapse, one co-existing leg ulcer, and one cerebral sclerosis and bed-sores.

The complications noted from which recovery ensued (while being treated with iron and quinine) were three suppurative otitis media, three abscess of the eyelids, two delirium tremens, and bronchitis, sciatica, diarrhoea, acute nephritis, broncho-pneumonia, lobar pneumonia, iritis, abscess of foot, tonsillitis, angina pectoris, and mastoiditis and fracture of the skull, one each; one instance arose during convalescence from typhoid, ending in recovery. When such facts as the gravity of the type of the present series and the character of the complications are kept in remembrance, the high mortality on the one hand and the apparent inefficacy of these remedies in combination on the other hand, need excite no surprise. My own experience in the use of quinine in erysipelas has been quite encouraging. During the past decade I have employed it in not less than twenty-four cases, its use being confined to instances in which the temperature touched 103° F. With a single exception, in uncomplicated cases (eighteen in number) the nocturnal remissions were decidedly greater and the evening exacerbations less marked. In every instance iron in some form (usually the tincture of the chloride) was administered simultaneously.

During the years from 1881 to 1892 inclusive, twenty-six cases were treated in the Pennsylvania Hospital by the use of pilocarpus, quinine being also associated in four of the cases and in two iron. There were seventeen of the idiopathic and seven of the traumatic variety, while the complications consisted in, one delirium tremens, one acute articular rheumatism, one diarrhoea, and in two a relapse occurred; none of these proved fatal. These results create a favorable showing for pilocarpus, but it is to be stated that in but few cases were there manifested serious complicating conditions.

Pilocarpus tends to produce increased nocturnal fall of temperature. The fact, however,

needs to be emphasized that there is a strong disposition to spontaneous nocturnal remissions in temperature in this disease. Professor J. M. Da Costa first used pilocarpus in erysipelas at the Pennsylvania Hospital. His experience soon showed clearly that when given in the very early stage, in  $\frac{1}{6}$ -grain doses hypodermically, repeated three or four times, at intervals of two or three hours, it often aborted the attack.

If we except its use to abort the affection, it is only in cases attended with high temperature without decided morning fall that pilocarpus should be employed.\* As a guide to the administration of this drug, the conditions of the pulse and the heart can be relied upon. Pilocarpus, then, deserves a permanent place in the therapy of erysipelas.

But, though I have been unable to obtain complete data showing the treatment and its results from the records of the Philadelphia and Episcopal Hospitals, the facts, so far as ascertainable, indicate that for twenty years the tincture of the chloride of iron in large doses has been most frequently used with the same good results as at the Pennsylvania Hospital. Quinine has been another favorite, administered in doses of 2 grains every three hours, or 10 to 15 grains once or twice daily.

In twenty-four cases, gathered from various sources, ergot gave decidedly favorable results.

*The Treatment of Severe Symptoms.*—Of drugs, as antipyretics, phenacetin, acetanilid, and antipyrin have been used at the Philadelphia Hospital,—a method of practice which I regard as being fraught with grave consequences. The best mode of reducing temperature is by means of cold sponges and cold or cool baths. The ice-bag applied to the crown of the head lowers temperature and simultaneously allays delirium and nervous excitement. For the marked nervous phenomena, such as pain, sleeplessness, and active delirium, hyoscine hydrobromate,  $\frac{1}{100}$  grain hypodermically, has been tried in numerous instances at the Medico-Chirurgical, Pennsylvania, and Philadelphia Hospitals, and has given promise of being a valuable remedy. It should not be employed where the heart-power is found to be greatly deficient. To fulfil the same indications, the following remedies and recipes, named in the order of their value and importance, have been utilized: Sodii bromidi, 5 grains every two hours or 20 to 30 grains at night; morphine ( $\frac{1}{8}$  grain) and chloral (10 grains) in combina-

\* It has been used by myself and others to a considerable extent at the Philadelphia Hospital for its antipyretic effect.

tion every half-hour for three doses; potassii bromidi (10 grains) and tinctura cannabidis indicæ (10 minims) at bedtime; atropine ( $\frac{1}{80}$  grain) and morphine ( $\frac{1}{16}$  grain) hypodermically.

3. *Local*.—Local measures have always held a prominent place in the treatment of erysipelas. The list of agents which have been used topically is long and embraces all classes of therapeutic substances. Thus, in the three series of cases before cited, which were treated at the Pennsylvania Hospital, together with a few collected from other sources, no less than fifty different remedies and preparations have been employed. Among those most frequently used were: elm in thirty-seven cases, lead-water and laudanum in twenty, subcutaneous injections of carbolic acid (1 to 40) in eighteen, oxide of zinc in fourteen, corrosive sublimate in solution in fourteen, vaseline or cosmoline in thirteen, solution of bicarbonate of sodium in nine, and benzoated zinc ointment, cocaine with laudanum, and ichthyol ointment with lanolin in eight each. Among the many measures of which trial has been made in a smaller number of instances are: collodion, glycerin, laudanum, unguentum potassii et belladonnæ, unguentum plumbi, liquor acidi carbolic, liquor chloralis, liquor sodii hypsulphitis, liquor sodii sulphatis, aqua calcis, mistura olei lini et bismuthi, unguentum sulphuris, mistura etheris et camphoræ (employed until a distinct coat is obtained), iodoform (and dry gauze) once daily, together with such simple and yet curiously varied measures as, dust affected parts with flour, zinc and starch, sassafras, apply hot flaxseed poultices (every two hours), cold-water cloths, warm-water cloths, ice-bag, wet cloths, lotions, and so on.

I have mentioned a large number of external applications,—by no means all of them,—at the risk of exhausting the patience of my hearers, for the express purpose of showing thereby the highly unsatisfactory condition which has characterized the local treatment of this disease down to the most recent times. Doubtless many of the preparations before mentioned were prescribed for their effect in excluding the air. To my mind this is a leading indication, and to meet it I prefer carbolized vaseline or cool carbolized oil.

A knowledge of the microbic nature of erysipelas has led to the employment by the profession of various antiseptic drugs and their application in various ways. I do not doubt that it is along this line that the greatest advances are to be expected. Allusion has been

made to the injection of carbolic acid. Here the aim is to check the spread of the inflammatory process by inserting the needle at numerous points just beyond the inflamed border. This method, introduced by Heuter, has been much practised by Henry at the Philadelphia Hospital, and more recently by Osler at Johns Hopkins Hospital. The success thus attained is encouraging, and the method is especially applicable in erysipelas migrans. As before stated, the solution of the bichloride of mercury (1 to 4000) was used locally in fourteen instances, and to these I can add the results of twelve others treated at the Medico-Chirurgical Hospital and in private practice. It may be applied in the form of lotions to the inflamed surface, or it may be injected beneath the skin, just beyond the border of the inflamed area, as in the case of carbolic acid. Quite recently it has been recommended to scarify the affected part and follow by the application of a solution of mercuric bichloride. This method of treatment I regard as being most promising as well as rational. It was certainly, in three instances in which it was resorted to in my own practice, followed by rather brilliant results, moderating more particularly the severity of the local inflammation.

Dr. Morris Booth Miller observed in the wards of the Pennsylvania Hospital quite uniformly good results from the local use of ichthyol ointment with lanolin, in the service of Dr. Da Costa and others. Before making trial of the corrosive-sublimate solution, I had used ichthyol locally, but the results were not brilliant. Dr. Charles J. Whalen has reported, in a recent issue of the *Journal of the American Medical Association* (April 28, 1894), most strikingly favorable results in four cases of facial erysipelas from the use of external applications of guaiacol,—a mode of treatment which richly deserves a more extended trial.

Lastly, from the results of these statistical investigations into the subject of the treatment of erysipelas, and personal observation and experience, I have arrived at the few brief conclusions following:

1. Proper attention to the diet is of paramount importance.
2. Stimulants are rarely necessary if the dietetic requirements are fully satisfied, but may be freely exhibited when indicated.
3. Of drugs, iron has been widely tested and found to be of great value, though it matters little which salt or preparation is employed.
4. Quinine, when administered with iron, reduces the temperature, supporting at the same time the vital functions.

5. The use of antiseptics *per drem* is to be recommended.

6. Pilocarpus is in a small proportion of cases powerful to abort the affection. To reduce temperature merely, pilocarpus should be employed in intense pyrexia, particularly where the favorable morning remissions do not occur.

7. The question of the local treatment of erysipelas has not as yet been set at rest, but agents intended to exclude the air and such as possess a germicidal power, especially corrosive sublimate, are highly useful.

8. That the erysipelococcus of Fehleisen, which is found chiefly in the more superficial channels of the corium, may be attacked directly by the corrosive-sublimate solution when the latter is used after scarification, is quite probable.

9. In erysipelas migrans, the germicide should be injected beneath the skin, just beyond the edge of the part inflamed.

#### TREATMENT OF HYDROPHOBIA.

BY CHARLES W. DULLES, M.D.

THAT strange mixture of independence and self-deception, Paracelsus, who broke up some traditions which had long acted as fetters to men's minds and with equal ruthlessness trampled under foot what his contemporaries regarded as common sense and common decency, signified the contempt he felt for them and that which they honored by publicly burning the writings of Hippocrates, Galen, and other great physicians of the olden time. Like him, in some respects, are those who in our day ignore or despise the works of the men who worked before them: works with which, for the most part, they seem to be unfamiliar. But he who would justly judge the methods of the present ought to know by what steps they have come to be accepted, and should not assume that the sum of experience which lies behind them is of no value. This is especially true when we consider that curious disorder known as hydrophobia, which Aristotle, of the ancients, first described nearly four centuries before the Christian era as a disease (*lyssa*) which caused in dogs mania, and in all animals bitten by dogs suffering with *lyssa*, mania, *excepting in man*.

The treatment of this disorder has been sometimes rational and sometimes strangely irrational, as have been the views in regard to its nature. Celsus justly called it *miserimum genus morbi*, and suggested a mode of treatment calculated to cure all those in

whom it was a pure psychical disorder. Pliny the Elder reported a large number of senseless and superstitious remedies employed before his time, among them a certain slimy spittle found beneath the tongue of a mad dog, which, taken in drink, was expected to prevent hydrophobia, and the practice of eating—raw, if possible—the liver of the dog that had inflicted the injury. Galen, with his extensive knowledge of drugs, especially recommended the ashes of river crabs burned on a copper plate,—a mild saline remedy; and Cælius Aurelianus recommended bleeding to cure fever, if present, and fear if there were no fever. After this, at various times, there have been recommended the use of oxalis and alysson among herbs, and of antimony and mercury among metals. In 1625, Aromatarius, considering hydrophobia to be a contagious angina, recommended the practice of laryngotomy, curiously anticipating a suggestion made nearly three hundred years later by Rush, soon after Physick had recommended tracheotomy in this disease. Boerhaave recommended bleeding *ad deliquum*, and to blindfold the patient and cast him into a cold pond. Ravely, in 1696, recommended emetics, diaphoretics, diuretics, and purgatives, with mercury and camphor internally. He also proposed the transfusion of arterial blood from a healthy animal, preferring the he-goat for reasons which he states. About this time (1700) Sir Theodore Mayerne proposed to the British public the following interesting procedure, which was calculated not only to serve as a test of the state of a dog suspected to be mad, but also as a curative method in case it was: "Pluck the Feathers from the Breech of an old Cock, and apply it bare to the Bite, and do this upon each of the Wounds. If the Dog were Mad, the Cock will Swell and Die, and the person Bitten will do well; but if the Cock Dies not, the Dog was not Mad. If the Wounds be very small, it is requisite to open them with a Lancet." In the same century Dr. Mead prepared his famous pulvis antilyssus, which in 1721 was inserted in the London Pharmacopœia, and which was regarded by many as a sure cure for hydrophobia. In 1732, Desault, regarding hydrophobia as a disease analogous to syphilis, used inunctions with the "Neapolitan ointment," composed of equal parts of human fat, hog's lard, and mercury. About the same time appeared the famous Ormskirk remedy, made of chalk, Armenian bole, alum, elecampane root, and oil of anise. Robert Whytt, in the eighteenth century, used opium in large doses, and one of his followers gave as

much as one hundred and eighty grains to a patient within twelve hours, with which and other treatment the patient lived just fifteen hours. In 1784, Mattheis, a Neapolitan surgeon, proposed the bite of a viper as a cure of hydrophobia; and four years later Fabbroni reported a case in which he made two vipers bite, one each leg of a man with so-called hydrophobia, who seemed to be relieved for the moment, but died in half an hour. In 1789, Dr. Percival quoted from Abbé Grosier a description of the Chinese serpent-stone, which is what is popularly known as the mad-stone. A good description of such a mad-stone and its uses is to be found in the unpublished correspondence of Dr. Benjamin Rush, now deposited in the Ridgway branch of the Philadelphia Library.

The time of Rush was the time of excessive use of bleeding and mercury. Rush recommended the letting of as much as one hundred or two hundred ounces of blood in order to effect a cure. After this came the suggestion by Rossi of the use of galvanism, while Youatt, the English veterinarian, had an extravagant faith in cauterizing the bites of mad dogs with nitrate of silver, and advised its use even if the constitution had been affected. In 1820, Marochetti announced that he had learned from a Cossack peasant of the Ukraine of the presence of certain vesicles (known as lyssi) beneath the tongue, the excision of which would prevent the outbreak of hydrophobia. This was not a novelty, and it was nonsense, although such serious writers as Trousseau and Doléris have attached some importance to it. About the same time Urban described certain vesicles, which he said were developed at the seat of the bite, and which contained a virus that was inoculable. In 1821, Magendie treated so-called hydrophobia with intravenous injections of warm water. In 1831, Trousseau—then a young man—at the suggestion of Magendie, gave to a patient 36 drops of hydrocyanic acid. By a mistake of the apothecary he administered the strong acid, and the patient died within twenty-four hours. The use of belladonna and atropine was so vigorously carried on in 1862 that Bergéron reported a case of a child, twelve and one-half years old, to whom he gave hypodermic doses of  $\frac{1}{16}$  grain of atropine. In 1866 the *Xanthium spinosum* was brought forward and extravagantly praised as a remedy for hydrophobia, but it soon went the way of all other sure cures.

Among the recently used remedies for hydrophobia are morphine, chloral, curare, cannabis indica, chloroform, nitrite of amyl, electricity,

oxygen, hoang-nan, and pilocarpine. Of these—to save time—I may say that not one commends itself to a critical judgment, except it be cannabis indica and, as we shall see, the combination of chloroform and morphine in carefully-selected cases. A careful study of thousands of cases reported, and of a limited number seen in practice and in consultation, has convinced me that the treatment recommended in text-books, and almost invariably followed in private and hospital practice, is not only useless, but in a great majority of cases very hurtful. Reflection on the records of many cases that I have examined, taken in connection with what I have seen, satisfies me that more patients would recover from attacks of so-called hydrophobia if there were no physicians, than do so now, and certain drugs I have come to regard as of the most hurtful influence. These are morphine, chloral, belladonna, curare, and chloroform. Over and over again I find records of the persistent use of these drugs, without the slightest evidence that they do any good whatever. Preparations of opium seem to increase maniacal excitement, and at a certain point to kill the patient, apparently by accumulation. Curare produces nothing but an apparent peace, caused by paralysis of the muscles, while the mind of the patient continues to be tortured. An example of this may be found in the record of a case reported in the *Lancet* of October 15, 1881. The significant conclusion of this report states that, after an attempt to chloroform the patient had to be discontinued,  $\frac{1}{16}$  grain of curare was administered hypodermically at 4.20 P.M., and that the patient “died quietly at 4.30 P.M., asphyxiated.” Hoang-nan, after a full trial, was abandoned ten years ago. Jaborandi and pilocarpine have followed it into disuse. The use of chloroform was first proposed by Dr. Henry Hartshorne, of Philadelphia, in 1848; and that of nitrite of amyl by Dr. Wm. S. Forbes, of Philadelphia, in 1875. Oxygen was used first in Russia in 1879. Of these three agents, it may be said that they would be of service in cases suitable from the stand-point of the neurologist, but that they cannot have, and do not have, any influence upon a disorder due to the action of a specific virus.

And now let us consider what remains, as a result of a careful consideration of the accumulated experiences of the past, to guide us in determining how any particular case of hydrophobia shall be treated. The first point, of course, is to be sure of the diagnosis. To do this implies a correct notion of the nature of the disorder. Any fair student of the subject

must agree that many cases are reported and treated as hydrophobia which are not caused by inoculation of any virus derived from a rabid animal, but are instances of a variety of diseases in which hydrophobic symptoms occur. This subject I have discussed quite fully in a paper read before the Medical Society of the State of Pennsylvania in 1884, giving a large collection of diseases which may be mistaken for hydrophobia. Each patient supposed to have hydrophobia should be most critically examined from head to foot, omitting no organ whatsoever. Especially should the condition of the ears, the throat, the lungs, the heart, the pericardium, and the kidneys be investigated. Rheumatism should be especially borne in mind, as well as alcoholism, and mania dependent upon central lesions or disorders. Pure hysteria, and that remarkable and horrible form of fright which comes to those who have a dread of impending disaster, must be considered. These things being done, and the presence of a disease independent of any specific inoculation being reasonably excluded, it will be found that the disorder is one whose manifestations are those of a psychosis, and its rational treatment must be such as is appropriate to disorders of this class. Good results are to be obtained only by the use of remedies which are found to be useful by persons of large experience in the management of mental and nervous diseases. One such remedy is *cannabis indica*, to control delirium and hallucinations. This may be given in the form of a tincture or extract, using moderate and repeated doses. The dose of the tincture should be 15 minims and that of the extract  $\frac{1}{4}$  grain, and such a dose may be given every half-hour until drowsiness is produced. The use of hyoscine hydrobromate commends itself upon theoretical grounds. I have no knowledge that it has ever been used in hydrophobia, but its great value as a calmative in various forms of delirious and maniacal excitement suggests its use in this disorder. It may be given in a dose of  $\frac{1}{16}$  grain hypodermically, repeating this in half an hour, and remembering its reputed depressing influence upon the heart. I believe that good might result from the use of the modern synthetical hypnotics, such as sulphonal and trional, given in doses of 20 grains in a tablespoonful of hot water every half-hour until sixty grains have been taken. I have sometimes thought that in some cases it might be well to try the effect of what is known as mixed narcosis, recommended in 1877 for surgical operations by Nussbaum. This consists in giving a hypodermic injection of a full dose

of morphine—for an adult,  $\frac{1}{2}$  grain—and within fifteen minutes administering chloroform by inhalation. This might secure the quieting influence of morphine during the period in which the frenzy and violent physical exertion of the patient were controlled by chloroform. My observations lead me to believe that one reason why morphine has never done any good in a case of hydrophobia is, that the extreme mental and bodily excitement of the patient prevented it from exercising its usual physiological action until it was accumulated in such a quantity in the system that it produced death.

To summarize, I think the only medication of hydrophobia which offers any chance of being successful consists in the use of *cannabis indica*, hyoscine hydrobromate, one of the synthetical hypnotics, or mixed narcosis. I think that the synthetical hypnotics deserve trial, especially as they are free from the objection to which the vegetable hypnotics are open—namely, that they themselves may produce delirium or even mania.

My experience leads me to believe that, with a little ingenuity, drugs may usually be administered by the mouth to patients with hydrophobia. In case, however, this is impossible, the remedies just described, except chloroform, can be administered hypodermically, with such antiseptic precautions as are now used whenever the skin is punctured.

Having thus spoken of the medicinal treatment of hydrophobia, something may be said in regard to what is probably of greater importance—namely, the general management of such patients. This involves certain things which, I think, are of the utmost importance; and, first, that the physician should understand that, notwithstanding the conflicting views in regard to the nature of the disorder, there is absolutely nothing in its symptoms—if it be deserving of a special name—which is not amenable to the methods of treatment adopted by neurologists in the treatment of persons suffering with grave nervous disorders, and especially of those cases in which there is delirium, hallucinations, or mania. The second is, that there is nothing in the patient which is dangerous to his attendants or friends, except as any maniacal patient may do bodily harm. The literature of hydrophobia—with which I think I may say I have a rather thorough acquaintance—does not furnish a single trustworthy instance of the communication of hydrophobia from a hydrophobic patient to a human being. I once had occasion to act upon my convictions in this respect. In treating a well-built boy,

sixteen years old, who had been held down in bed by a number of men, and was in a furious state of excitement, I secured moral control of him, to the terror of those who looked on, by announcing my intention of listening to his heart, and then putting my ear on his naked chest, while I looked into his face for the space of a minute or two—it seemed rather a long time to me. If a physician wishes to do any good in a case of this kind he must have no fear, or at least show no fear to those in the sick-room. In like manner it should be known that physical restraint is hardly ever necessary. Of course, as in other forms of mania, the time may come when force must be used; but I know from experience that it is not required in many cases where it is used. Likewise no attempt must be made to make a diagnosis of hydrophobia by testing the patient's ability to eat and drink. These things are absolutely unnecessary to the diagnosis and extremely hurtful to the patient. It ought to be regarded as a mark of incapacity for a physician to make such tests after the patient has once shown or expressed repugnance to liquids or inability to swallow. As to the necessity of administering liquids for the sake of the fluids they contain, this can be met in two ways: in the first place by enemata of water, in the second place by immersion in a bath. The latter has been used—that is, the hot bath—as a remedy. But it must be borne in mind that hydrophobia does not kill by famishing or starvation, and it would be better to give a patient a chance to get well at the cost of being exceedingly thirsty and hungry rather than to torment him with drink or food, given by the mouth or rectum. I wish to lay especial stress upon this point, for it is saddening to one who is interested in this subject to see what is published, and copied from book to book on the practice of medicine, in regard to this matter. Long ago it has been shown that one of the best modes of treatment of tetanus in man and animals consisted in confining patients in a partly-darkened and quiet apartment, in absolute solitude; while no one can study this subject without seeing that the medication hitherto recommended is absolutely good for nothing, and the suggestions to maintain the strength while the disease is in progress are in diametrical conflict with every principle of nutrition.

Writers on this subject ought to know more about the function of nutrition, as physiologists understand it, than to recommend the introduction of articles of food into the stomach or rectum under such circumstances as are present in a case of so-called hydrophobia. I wish it

were possible to make in regard to this the impression which I think is correct. It ought to be the rule in a case of hydrophobia to reduce physical restraint and medical treatment to the very lowest point, and to make no attempts at feeding. In some cases I am satisfied that the best thing to do would be to dress the patient in his clothes, put him in a carriage, drive him out into the country, and set him to work in a field or walk him about in the woods, or otherwise to get his attention off of himself. I believe by this treatment many of the cases that could be properly called hydrophobia would get well. It is on record that an English physician once, finding himself developing symptoms of hydrophobia after a dog-bite, determined that he would not die in his bed, but, if necessary, in his boots. So he got up, took his gun, called his dogs, and started out on a hunt, returning at the end of the day thoroughly fatigued and thoroughly cured. This principle underlies the teaching of that wise man of his time, Celsus, and would probably prove more successful than the methods now recommended in text-books on medicine; it certainly could not prove less successful.

To sum up: in the treatment of hydrophobia, the important things are, first, to make an accurate diagnosis; second, to be honest but fearless with the patient; third, to avoid forcing the patient in any way, for food or medicine, and especially for drinking; fourth, to avoid violent medication; fifth, to follow a consistent, common-sense, and harmless line of treatment, not changing from one thing to another of unproved value.

4101 WALNUT STREET, PHILADELPHIA.

#### TUBERCULAR PERITONITIS.

CROFFORD (*American Journal of Obstetrics*, April, 1894), after reporting a number of cases, states that tubercular peritonitis is an operable disease. The immediate danger from the operation is not materially influenced by the character of the inflammation.

An early operation is of greatest value.

The chronic or slowly progressing variety offers the best indications for surgical interference.

When the primary deposit is in the tubes, which Winckel declares to be in fifty per cent. of the cases, an early salpingotomy will cure the disease.

Operations later in the disease will frequently prolong life and possibly cure.

### THE TREATMENT OF THE INTESTINAL HEMORRHAGE OF TYPHOID.

THERE are few accidents occurring to the patient during typhoid fever which create so much alarm in all the persons concerned as hemorrhage from the bowel. While it is true that in some cases this accident is followed by a great amelioration in the symptoms, the very fact that at the time it is impossible to estimate the freedom of the flow of blood renders the anxiety intense, and the physician feels called upon to use every measure which is rational for the arrest of the hemorrhage. Probably the most efficient treatment which he can attempt is the application of a small ice-bag over the region of the ileum, with the hope that the external cold may have some effect upon the intestinal circulation, and to administer by the mouth Monsel's salt—that is, the subsulphate

of iron—in pill form, in the dose of 2 or 3 grains. These pills should be of sufficient age to make them difficult of solution, in order that they may escape through the stomach without being dissolved and decomposed by the juices of that viscus. To administer Monsel's solution under such circumstances is practically futile, because of the occurrence of its decomposition, as is also the administration of gallic or tannic acid, unless they are given in tough capsules or in coated pills, in such a way as to enter the bowel intact. The patient should also be placed flat upon his back and with the head as low or lower than his heels, and, should the hemorrhage be profuse, the foot of the bed should be very distinctly elevated, and bandages applied to the limbs to keep the blood circulating in the vital parts.

A very nice question in the treatment of such cases is that which covers the administration of stimulants. If stimulants are given, there is danger of displacing the clot with which nature may be closing the ruptured blood-vessel in the intestine. Yet, on the other hand, as the circulation fails and the patient becomes pulseless, the physician feels that active stimulation is absolutely necessary. We believe that the stimulant should not be employed until after bandaging of the extremities and elevation of the foot of the bed have been resorted to, and then it should be given most cautiously if needed. It is, moreover, important to maintain the bodily heat, and hot applications should be placed about the patient.

Our attention has been particularly called to this point by reason of an article upon this subject in one of the French journals, in which ergotine and similar remedies are advised. We believe that this treatment cannot be criticised adversely, and yet that it can actually exercise but little good. While it is true that ergot has a greater influence upon diseased blood-vessels, in all probability, than upon normal ones, the condition under these circumstances is not that of oozing from dilated capillaries, but from a distinct rupture of the coat of a blood-vessel, and we do not see how ergot can exert a sufficiently positive influence over the wall of the injured blood-vessel to actually stop the leak.

The employment of transfusion, either of human blood by the direct method or the transfusion of normal saline solution in the strength of 7 to 1000, offers very distinct advantages. Indeed, we are inclined to advise the employment of the normal saline solution injection intravenously, rather than the administration of stimulants which will be poorly ab-

sorbed, whether given by the mouth or hypodermically, owing to the feebleness of the circulation. Even if stimulants do not disturb the clot, they can do but little good, since the heart is not so much at fault as is the lack of blood. Whether the profession will ever have statistics which encourage them to open the abdomen and seek the point of hemorrhage is a question. While this is a much-to-be-desired advance in medicine and surgery, the mortality of the operation so far is so great, probably because of the exhausted condition of the patient, that surgeons are not encouraged to repeat the experiment.

#### THE ADMINISTRATION OF IODINE BY THE RECTUM.

THE *Journal de Médecine de Paris* for April 29, 1894, after pointing out that many patients are unable to take iodine compounds by the mouth, recommends their rectal injection, and there is little doubt that frequently this means of placing iodine in the body is of advantage. In our own experience we have found that in many cases in which iodine immediately produced gastric disorder, large doses of iodoform dissolved in oil or in suppository could be given by the rectum, and that constitutional disturbances were rapidly manifest, the patient often tasting the iodine in the saliva very soon after the treatment was instituted. The dose of iodoform which can be most frequently administered under these circumstances varies from 2 to 10 grains, according to the needs of the case and the ability of the bowel to absorb, coupled with the readiness with which the system responds to the drug. The injection which was recommended in the article which we have quoted is somewhat different from these, and may be given as follows:

- R Iodide of potassium, gr. xlv;
- Bromide of potassium, gr. xxx;
- Extract of belladonna, gr. v;
- Water, ℥xii.

To be divided into twenty parts, each one of which shall be added to two to four ounces of hot water at the time of the injection. Much larger amounts of iodide of potassium may be employed and smaller amounts of the bromide. The conditions in which the French authors recommend this injection are in hypertrophy of the prostate and in syphilitic ulceration of the rectum. The conditions in which we have found these injections serviceable have been in cases of syphilis, in ulceration of the bowel,

and in chronic catarrhal processes where the peculiar effects of iodine upon mucous membrane were eminently desirable. The object in doubling the bromide is to allay the irritability of the bowel, which may be produced by the use of an irritant substance, as the iodide of potassium, and it is for this reason that we so greatly prefer the iodoform.

#### TRIKRESOL: A NEW GERMICIDE.

AT the Fourth Meeting of the Association of Military Surgeons of the United States, held in Washington, May 1 to 3, 1894, attention was called to the valuable qualities of trikresol in general surgical work ("The Germicidal Value of Trikresol," by Walter Reed, surgeon U.S.A.).

After briefly reviewing the various mercantile preparations of the coal-tar derivatives, such as aseptol, creolin, lysol, solveol, solutol, saprol, etc., Dr. Reed called attention to Henle's painstaking investigation of creolin (A. Henle, "Ueber Creolin und seine wirksamen Bestandtheile," *Archiv für Hygiene*, Band ix., 1889). Henle's observation that cresol, as well as phenol, dissolves very well in soap solution, was important; and especially valuable was his conclusion that the germicidal value of creolin was due to some body contained in the tar oil of which it is made, and which body stands very near to cresol. This appeared to be a legitimate deduction, for inasmuch as creolin contained so little phenol and yet exhibited a high disinfectant power (*Staphylococcus aureus* being killed in a half-minute by a five-per-cent. aqueous solution), it was natural that Henle's attention should be directed to the insoluble hydrocarbons, the homologues of phenol, contained in tar oil.

Reed thinks that much credit should be given to Laplace, of New Orleans, for the work which he did bearing directly on this subject. While working under Koch, in 1888, Laplace mixed equal volumes of crude carbolic and concentrated sulphuric acids, and found that he had thereby obtained a dark, syrupy liquid, which was easily soluble in water and which possessed remarkable germicidal power. A two-per-cent. watery solution of the mixture destroyed anthrax spores in seventy-two hours, whereas a two-per-cent. solution of either carbolic acid or creolin was absolutely without influence. Here, then, was taken the first step in the evolution of the germicide which is at present attracting so much attention in Germany. Carl Fränkel's exhaustive review of Laplace's work

(*Zeitschrift für Hygiene*, Leipzig, 1889, Band vi.) proved conclusively that the body evolved and brought into solubility by mixing crude carbolic and sulphuric acids was none other than *kresol*, and not only confirmed Laplace's observations, but extended them considerably.

Arising from the important work of Laplace and Fränkel, a number of investigations have been carried on, during recent years, in Germany, by chemists, bacteriologists, and surgeons, growing out of the study of these higher homologues of carbolic acid,—viz., the *kresols*. These differ from phenol by having one atom of hydrogen replaced by the methyl-group  $\text{CH}_3$ . Thus, if we represent carbolic acid by the formula  $\text{C}_6\text{H}_5\text{OH}$ , that for *kresol* would be  $\text{C}_6\text{H}_4\text{CH}_3\text{OH}$ . There are three of these bodies, known as ortho-, para-, and meta-*kresol*. The first two are crystalline bodies, the third appearing as a colorless, thickish fluid, whose boiling-point is about  $201^\circ \text{C}$ .

Much difficulty has been experienced heretofore in trying to obtain these isomeric *kresols* in a pure state; but recently quite a step forward has been made in chemical methods, and they are now manufactured in a pure state from coal-tar, the three being presented together, and happily named *trikresol*.

The latter is a white liquid, of a creosote-like odor, specific gravity 1042 to 1049, and soluble in water to the extent of 2.55 per cent. Its solutions are clear, and, unlike solutions of carbolic acid, do not impart any sensation of numbness to the fingers and hands of the operator. It is also said to be less irritating to wounds than either carbolic or bichloride solutions.

As regards its great value as a germicide, Grüber (*Archiv für Hygiene*, 1893, Band xvii. S. 618) and Reed bear strong testimony; one-per-cent. solution of *trikresol* kills the pyogenic cocci in watery solutions invariably in half a minute. The same strength solutions in rich albuminous fluids require one and a half minutes to destroy *Staphylococcus aureus*. Its action is thus seen to be unusually prompt, even in the presence of albumin, which is an important point in its favor as compared with the older germicides.

Finally, its poisonous qualities are rated as slightly less than carbolic acid; but since one-per-cent. solutions of this agent accomplish the work of five-per-cent. solutions of carbolic acid, the danger from poisoning is greatly diminished. We invite the attention of the profession to this new germicide, which, to us, appears to promise a wide field of usefulness in surgical and gynecological work.

#### LEGISLATION FOR THE PREVENTION OF BLINDNESS FROM OPHTHALMIA NEONATORUM.

IT is a well-established fact that purulent conjunctivitis is responsible for most of the cases of blindness in young children, Magnus, of Breslau, having computed from carefully-compiled statistics that fully seventy per cent. of those who become blind during the first year of life owe their affliction to this disease, while Rivière, of Bordeaux, has shown that purulent ophthalmia alone has placed in the care of Europe nearly one hundred thousand victims.

It is further established by the census returns of 1880, as compared with those of 1870, that blindness has increased in the entire country more than four times as rapidly as the population, while in some States the proportionate increase is still greater. (Consult Howe, *American Ophthalmological Society Reports*, July, 1890.)

Boerne Bettman (*Journal of the American Medical Association*, May 19, 1894), bringing this matter before the Chicago Medical Society, contributes the following information:

"If we consult the United States census from the year 1850 to date, we learn that the number of blind enumerated during the previous decades is as follows: 1850, 9794; 1860, 12,658; 1870, 20,320; 1880, 48,928; 1890, 50,411.

"If compared with the population, which increased from 23,191,876 in 1850 to 62,622,250 in 1890, we obtain the following ratios:

"Number of blind to 1,000,000 of population: 1850, 422; 1860, 403; 1870, 527; 1880, 976; 1890, 805.

"As we are especially concerned about the State of Illinois, it will be interesting to ascertain the number of blind allotted to us in the records quoted. The following table comprises both the total number of blind for each period and their ratio to 1,000,000 of the population:

"Number of blind in the State of Illinois: 1850, 264; 1860, 476; 1870, 1042; 1880, 2615; 1890, 2834.

"Number of blind to 1,000,000 inhabitants: 1850, 310; 1860, 278; 1870, 410; 1880, 850; 1890, 741.

"It will be observed that the proportion of these sadly afflicted has greatly increased, notably so in 1880, and again decreased in 1890. These apparent inaccuracies are due to the methods of enumeration adopted, and are fully explained in the following words of Dr. Wines, quoted from the Report of the Board of Public Charities of Illinois, 1892: 'With re-

gard to the so-called "defective" classes, it should be known that Dr. Wines, in 1880, supplemented the enumerators' returns by correspondence with physicians, who added many names to the lists. This correspondence was not renewed in 1890, which accounts, at least in a large degree, for the seeming slight falling off in the ratio in 1890."

It is also established that proper prophylaxis, notably Credé's method, in hospital practice and in all cases where known infection exists, and milder prophylaxis in private practice generally, is capable of reducing the number of cases of this disease to a minimum.

Finally, it is established, on the one hand, that failure promptly to recognize and properly to treat this inflammation results in disastrous consequences; while, on the other hand, if suitable measures are quickly and thoroughly instituted, before corneal complications arise, the majority of cases will be brought to a successful termination. The exceptions to this rule are those cases which from the beginning assume a diphtheritic type, or, as, for example, Dr. Randall has shown, those which, probably from some inherent malignancy not yet well understood, go on to destruction in spite of the best care and the most scientific treatment.

From what has been written, it is evident that measures to prevent ophthalmia neonatorum rank in importance with those which are employed against contagious diseases, and that success depends mainly upon promptness in therapeutic action. Therefore, as Dr. Howe has well shown that a mere attempt to educate the laity and nurses on these points is insufficient and even useless, it becomes necessary to invoke stringent legislative regulations against this appalling cause of blindness. Ever since 1887, Dr. Howe has devoted much attention and energy to this matter, beginning his labor by taking the subject before the American Ophthalmological Society, and finally last year before the American Medical Association, and it is in great measure due to his conscientious work that much good in this line has been accomplished.

At the present time New York, Maine, Rhode Island, Maryland, Minnesota, and other States have passed laws which have for their object the preventive treatment of this disease, the main sections in all the acts thus far adopted being the direction that the nurse or attendant shall at once report to the health officer, or a legally-qualified practitioner, if one or both eyes of the infant are reddened or inflamed within two weeks after birth, and that failure to comply with this provision shall be punish-

able by fine or imprisonment, or both. In this way, as Dr. Howe has said, the responsibility is placed where it belongs.

At the recent meeting of the Pennsylvania State Medical Society the text of an act similar to those already passed in other States was introduced by Dr. Gould, and it is earnestly hoped that physicians throughout this entire State will use every means to secure the passage of this act, so that this State may not be backward in adopting measures to check the spread of blindness.

## Reports on Therapeutic Progress.

---

### *TREATMENT OF ERYSIPELAS WITH HYPODERMIC INJECTIONS OF CARBOLIC ACID.*

In the *Medical and Surgical Reporter* for March 24, 1894, GASTON reaches the following conclusions in a paper on the treatment of erysipelas with hypodermic injections of carbolic acid. In only one patient did this treatment fail. In this instance he was called in consultation at an advanced stage of erysipelas involving the entire scalp, accompanied with coma. As an offset to this, he has frequently employed the carbolic acid hypodermically when the scalp was partially involved in erysipelas, with complete relief.

He alludes to a case at term with erysipelas, in which there was face presentation requiring podalic version, and followed by erysipelas of the genitalia and the hypogastric region. The injections hypodermically of carbolic acid in various portions of the area affected were crowned with complete success.

The formula employed by the original reporter was a solution of carbolic acid in dilute alcohol. But this was modified by Gaston afterwards, and he has used for the past ten years the following:

R Carbolic acid, fgi;  
Glycerin, fgiij;  
Distilled water, fgiiv. M.

Inject hypodermically 1 syringeful in each portion of the size of a hand, daily.

It will be observed that this is a twelve-and-a-half-per-cent. solution, and only in a few cases has any local irritation resulted from the injection.

When the thickened and hardened condition of the skin has rendered it difficult to introduce the needle, he selects points on the border of the dermatitis to make the injection,

so as to reach the areolar tissue beneath the skin. There is little pain connected with it. Of course this treatment does not preclude resort to any internal treatment which may be indicated, and when the extent of surface involved is large or the febrile condition is great he has used internal remedies.

The best effects have been secured by giving at the outset calomel, followed by Epsom salts in senna-tea, to procure free evacuations from the bowels. After purgation he gives 25 drops of the muriated tincture of iron every three hours until an ounce is taken. In some cases chlorate of potassium in 10-grain doses has been combined with the iron, especially when there is a tendency to the phlegmonous form of erysipelas.

When the case is seen in its early stages, hypodermic use of the formula given above rarely fails to bring success. The writer details an interesting case of a man suffering from periodic recurrence of this disease in his feet and legs every spring. He had a well-developed case of erysipelas on both legs, extending up to the knees. The carbolic acid was used hypodermically in two places on each leg and repeated on two successive days, without any other treatment. All traces of the disease disappeared, and during five years subsequently there has been no return of the disease. This case indicates a specific action of carbolic acid in the cure of erysipelas.

The influence upon the system of such an injection is general and not confined to the immediate location of the puncture, so that it may be considered as a constitutional impression of the remedy. Some caution is requisite against an undue quantity of this solution of carbolic acid being used on one occasion, lest a toxic influence be manifested. He has repeatedly introduced a syringeful of the solution in four different places without producing any untoward effect, and hence it may be allowed that this quantity distributed over an area of four hand's breadth is entirely safe. It is also found proper to repeat the injections daily for three days, but it is not necessary to continue the treatment for a longer time.

#### *EFFECT OF MERCURIAL TREATMENT ON THE URINE.*

WELANDER (*Arch. f. Derm. u. Syph.*, xxvi., Part 3) says that great numbers of observations have shown that mercury is in large part eliminated by the kidneys. Does it irritate the kidneys? Welander made a number of observations on patients treated with different preparations

of mercury. He found that there are seldom casts or albumin in the urine of patients in the early period of syphilis; but in a later period, at the same time as gummata, patients may suffer from a peculiar form of acute nephritis, with blood-casts, fatty casts, etc., in the urine. This form of nephritis disappears, together with the other syphilitic manifestations, under specific treatment. Severe treatment with mercury often gives rise to casts and sometimes albumin in the urine, but neither the absence of these from the urine nor the absence of stomatitis shows that only little mercury is being absorbed; this can be determined only by examining the urine or fæces for mercury. The affection of the kidney dependent on mercurial treatment passes off fairly quickly and, as a rule, leaves no tendency to nephritis behind it, but in cases of acute mercurial poisoning actual lesions can sometimes be made out in the kidneys. Nowadays, by the centrifugal apparatus, casts can easily be found in the fresh urine, and Welander, from a series of observations, thinks that the finding of one or two hyaline or finely granular casts in the urine is no proof of any actual morbid structural change in the kidneys. When, however, the number of these casts is observed to increase, and especially when epithelial and blood-casts are also observed, it is certain that a more or less abnormal condition exists in the kidneys. These were Welander's former conclusions, and they are confirmed and extended by the following results of his recent observations. In a large number of cases he found that under mercurial treatment the number of casts was not increased in 23.2 per cent., but distinctly increased in 28.9 per cent., and considerably increased in 47.9 per cent. of the cases. In a few cases he was able to ascertain that the number of casts diminished or disappeared after cessation of the treatment, at least, after an interval, as might be expected, for the elimination of mercury by the kidneys lasts some time after cessation of the treatment. Mercury is more likely to give rise to urinary casts in old patients than in young ones, and Welander's observations seem to show that, apart from age, patients with tertiary syphilis are more likely than those with primary syphilis to get casts in the urine under mercurial treatment. It seems that the form in which the mercury is administered makes no difference in this respect, except in so far as concerns the quantity that is absorbed into the system and eliminated by the kidneys. The casts in the urine do not seem to be increased by the taking of iodide of potassium simultaneously with the mercury. When mercurial treat-

ment in a strong young man with primary syphilis gives rise to casts in the urine, this must be ascribed to idiosyncrasy, which, indeed, plays a great part in the whole matter. A certain degree of albuminuria is sometimes, as well as the presence of casts, evidently caused by mercurial treatment, and albuminuria, when due to mercury, is always associated with an unusual proportion of casts. Welander has observed that mercurial treatment may also induce the presence of casts and albumin in the urine in non-syphilitic persons.

The practical outcome of his observations is that mercury should be administered with great caution when there is disease of the kidneys, or when in the course of mercurial treatment albumin appears in the urine together with casts, more especially if some of the latter are epithelial. Moreover, when a patient is undergoing thorough treatment with mercury, a watch should be kept on his urine, as on the state of his gums, alimentary canal, and skin.—*British Medical Journal*, April 28, 1894.

#### THE USE OF A COMBINATION OF CARBOLIC ACID AND CHLOROFORM IN ENTERIC FEVER.

QUILL writes a paper on this subject for the *British Medical Journal* of April 28, 1894.

The combination of carbolic acid and chloroform was adopted for the following reasons: In 1892, Dr. McIntyre, of Glasgow, conducted some experiments in regard to the action of carbolic acid on the enteric bacillus (Gaffky's), and found that, in addition to an antiseptic action on the intestinal contents, the acid controlled the development of the enteric bacillus. Previously to this, in 1890, Werner, of St. Petersburg, made similar experiments with chloroform, and found that a one- to two-per-cent. solution of chloroform killed the enteric bacillus.

Reflecting on these experiments, it occurred to me that a combination of these drugs, both of which had a distinctive effect on the specific micro-organism of enteric fever, and one of which had as well a wholesome intestinal antiseptic action, ought, if given with judicious freedom, to be effectual in rendering immune the enteric bacillus and its septic products. So far these expectations have been realized.

He has treated with the carbolic acid and chloroform combination during the past year all the cases of enteric fever that have come under his care, and in each case perfect recovery has followed, without the advent of any symptom calculated to cause anxiety.

It is a gratifying experience to be able to make this record regarding a fever which in India has a mortality very considerably higher than that usually experienced in temperate climates.

The following are the effects he has observed as resulting from the use of the carbolic acid and chloroform combination:

1. A reduction in the average duration of the fever.
2. A continuous depression of the febrile temperature.
3. Early cleansing of the tongue, dryness of which was rarely observed, and was then evanescent.
4. An almost complete deodorization of the stools.
5. Abdominal distention kept in entire abeyance.
6. Tendency to diarrhoea checked.
7. Intellectual clearness of patient preserved, with no tendency to stupor or delirium.
8. Secondary complication of any kind never occurred.
9. Relapses rare; when they occurred they were of short duration.
10. Food invariably well assimilated.
11. Convalescence rapid.

#### THE IODIDE OF RUBIDIUM.

In syphilis, LEISTIKOFF proposes to replace the iodide of potassium with the iodide of rubidium. The advantages of the iodide of rubidium are the lack of disagreeable taste and the fact that the development of iodism is not so frequently produced. The dose is the same as that of the iodide of potassium.—*Journal de Médecine de Paris*, April 22, 1894.

#### EXCISION OF TONGUE AND OF SUB-MAXILLARY GLANDS. LIGATURE OF BOTH LINGUAL ARTERIES.

A note in the *Medical Press and Circular* for April 18, 1894, states that MR. G. SILCOCK operated on a man, aged about thirty-five, who had been in the hospital six months ago with a small patch on the tongue; this had been freely excised, a wide sweep being taken all round; at the time it was by no means certain what the growth was. However, at the present time the patient had come back with a recurrence, and it was decided to remove the whole tongue. As the growth was very far back, quite at the root, it was thought better to ligature both linguals. This was done in the usual way in a comparatively short time. Next a thread was

passed through the centre of the tongue and the organ drawn well forward and rapidly snipped away with the scissors, the operator beginning at the frænum and taking away the whole tongue and the anterior pillars of the fauces. The bleeding was necessarily very slight, but a deep vessel, which was thought to be the left ascending pharyngeal or one of its branches, gave a little trouble. However, a pair of forcipressure forceps eventually secured the bleeding vessel, and these were left on at the end of the operation for safety. Controlling the hemorrhage was much facilitated by the floor of the mouth being pushed up on the left side through the wound made by tying the lingual artery on that side. The next proceeding was the removal of the submaxillary glands; the one on the left side was hardened, and as a measure of prudence the one on the right side was also taken away. The removal of these glands gave rise to a lot of troublesome hemorrhage and materially prolonged the operation, as the arresting of the bleeding took some time and care. The wounds made for the ligature of the linguals served also for the excision of the glands. The opening on the left side extended through into the mouth during the operation, owing to the extensive removal of the base of the tongue on that side. Both wounds were lightly sewed up.

#### GUAIACOL.

DR. DESPLATS, professor at the medical faculty of Lille, was the first to note the antithermic effects of guaiacol when painted on the skin, but it appears that, as a sedative, it also constitutes a valuable resource in the treatment of certain painful affections. Thus, guaiacol not only suppresses rapidly the neuralgic pains so frequently met with in tuberculous patients, but also sciatica and rheumatism, where salicylate of sodium and antipyrin have failed. However, the application of guaiacol in its pure state is painful in itself and irritates considerably a delicate skin. For this reason M. Moissy mixes it with equal parts of glycerin, by which no inconvenience is felt. The dose to be employed is  $\frac{1}{2}$  drachm, but the painting can be renewed as the sedative effect has passed away,—that is to say, in about five hours. At the meeting of the Société Médicale des Hôpitaux, M. Balzer said that he had tried guaiacol in the treatment of orchitis with good results, in ointment (guaiacol vaseline). A burning sensation is felt for about ten minutes, after which the patient experiences a certain *bien-être* which

permits rest and sleep. Guaiacol has no resolutive effect on the swelling.—*Medical Press and Circular*, April 18, 1894.

#### THE TREATMENT OF NEPHRITIS.

In a lecture reported in the *Medical News* of April 21, 1894, DA COSTA speaks on this subject. He thinks that the salts of strontium are valuable as diuretics in renal affections, and they are particularly valuable in the acute forms, but do less good in the chronic forms. They do not, according to the writer's experience, act so much upon the structure or tissues of the kidneys as upon its secreting function; they are admirable diuretics. The claim that has been made by some French clinicians that strontium salts markedly reduce the amount of albumin in the urine has not been fully confirmed in the author's experience, except that the relative proportion of albumin is greatly reduced by the great increase in the quantity of the urine secreted. There is, however, some slight diminution in the amount of albumin, as well as increase in the quantity of the urine, especially in the acute forms. Whether in the parenchymatous and interstitial renal diseases these salts act beneficially upon the diseased or degenerated structures, or simply act as diuretics, has not been finally settled; but they certainly accomplish more good in the acute than in the chronic forms of nephritis.

To return to our patient. In treating this case we need pay less attention to restricting the diet than in the other cases. This man may have meat and vegetables and a nourishing diet, avoiding indigestible and highly-seasoned articles of food. For his treatment now he shall take bichloride of mercury,  $\frac{1}{16}$  grain, in a wineglassful of water three times a day, as a tonic to improve his tissues. This will be the treatment in this case, except that we will see, with the aid of the lactate of strontium, that the urinary secretion is kept free.

#### DYSPEPSIA IN WOMEN.

In an abstract of the Ingleby lecture on the common forms of dyspepsia in women, SAUNDBY thus speaks of medicinal treatment:

On account of the prevalence of anæmia in these cases iron takes a very prominent place in their treatment. Where this symptom is marked, we may give pil. ferri (Blaud's pill), sulphate of iron in mixture, so often usefully combined with sulphate of magnesium, or the tincture of the perchloride of iron.

Strychnine is extremely useful in combating the motor weakness of the stomach and intestine, and may be suitably combined with iron, or, in those cases where iron is not indicated, with a mineral acid, of which hydrochloric acid seems the most appropriate. A mixture in which these two drugs form the essential elements is very beneficial to the ordinary type of atonic gastralgia, and is thus formulated in the General Hospital Pharmacopœia :

R Ac. hydrochlorici dil., ℥x;  
Ac. hydrocyanici dil., ℥v;  
Liq. strychniæ, ℥iiss;  
Sodii chloridi, gr. xx;  
Glycerini, ℥xxx;  
Aq., ad ℥i.  
Ft. ht.

Sig.—To be taken thrice daily, an hour after meals.

Magnesium and sodium sulphate deserve early mention among the drugs which stand first in usefulness and in the frequency with which they are required. Constipation is the absolute rule in these cases, and of all aperients the salines are the best. When the patient is in bed the dose may be divided and given three times a day, but when she can get about it is better to give it the first thing in the morning on rising from bed. There is little to choose between the magnesium and sodium salt, except in their taste, of which, probably to most people, the former is more disagreeable. Either may be given in the shape of mineral water, of which Franz-Josef, Æsculap, Friedrichshall, and Hunyadi are among the best-known magnesium waters, and Carlsbad, Kissingen, and Rubinat the sodium waters. The last is one of the least disagreeable and most efficient, and can be strongly commended. Aperient waters may be taken hot or cold, and probably act better, as a rule, when hot. If really hot, they are less disagreeable, but if only warm, their nauseous taste is increased and may cause vomiting. Where there is gastritis, these salts or waters should always be taken in half a pint of water as hot as it can be sipped.

Abernethy said he would define biliousness as a condition curable by blue pill, and there should be no doubt of the value of this remedy in all cases of subacute gastritis. The drug may be given in the form of calomel or blue pill. The writer prefers the latter, and generally gives two 5-grain pills, one to be taken at bedtime on successive or alternate nights, according to the extent of its action. It unquestionably has the power of allaying gastritis, and in small continued doses is useful in the chronic form as well. How it acts—whether as an an-

tiseptic, or by unloading the vessels, or by both means combined—we cannot be sure, but its power in both these directions is indisputable, and no one will question the good results which follow its administration. That mercury was abused in the treatment of the early part of this century there can be no doubt. Sir Robert Christison used to illustrate this abuse by relating that when he was a young man attending St. Bartholomew's Hospital a discussion upon this subject arose among a company, of which the house surgeon formed one. In order to maintain his opinion, Christison offered to bet him that there were not ten patients in the hospital who were not at the time under mercurial treatment in some shape or form, but the house surgeon would not accept the challenge, so little certain did he feel of winning it. Nevertheless, the reaction that set in led to the undeserved disrepute and consequent neglect of one of the most generally useful drugs in the Pharmacopœia.

In the treatment of gastritis, whenever there is evidence of much irritation by pain, furred tongue, icterus, or mucous vomiting, etc., bismuth is indicated. It may be given in various combinations and forms,—for example, in subacute gastritis, with blue pill and a saline aperient, the following powder, to be taken three times a day before food :

R Bismuth. salicyl., gr. x;  
Sodii bicarb., gr. x;  
Pulv. rhei., gr. iii;  
Pulv. cinnamomi co., gr. v.  
Ft. pulv. xii.

It should be taken in milk, and is an excellent remedy for ordinary use. Where the bowels are irritable the rhubarb may be omitted. In chronic gastritis with mucous vomiting, the following may be given :

R Bismuthi carb., gr. xv;  
Sodii bicarb., gr. x;  
Muc. tragacanthi, ℥ss;  
Aq., ad ℥i. M.  
Ft. ht.

Sig.—To be taken thrice daily before meals.

In cases of atony, with slight gastritis :

R Liq. bismuthi et ammon. cit., ℥i;  
Sodii bicarb., gr. x;  
Tr. nucis vom., ℥x;  
Inf. gentianæ, ad ℥i. M.  
Ft. ht.

Sig.—To be taken thrice daily before meals.

We have seen that not very uncommonly there is distinct deficiency in the hydrochloric acid of the gastric juice ; it is difficult to give

as much as is needed to compensate for defective secretion, but 15 drops in a wineglassful of water may be taken through a tube every hour for four hours after each meal. Pepsin is much more rarely absent, as so little of the ferment is actually necessary; but when artificial digestion has determined the want of it, it may be very easily supplied by any of the good preparations now in the market. In connection with the use of these remedies, it may be said that they do not do so well as might be expected, nor does their absence produce the ill effects we should anticipate. In fact, so long as the food is not retained too long in the stomach, its chemical condition is of comparatively little importance, the deficient digestion in the stomach being made up by the activity of the pancreatic and intestinal juices. It is, therefore, to the various means for promoting motor activity that we should chiefly look in the treatment of these cases.

#### NEW APPLICATIONS OF CAFFEINE IN DISEASES OF THE HEART AND KIDNEYS.

In the *Journal de Médecine de Paris* for April 22, 1894, is an article by PAVINSKY on a series of experiments made by him concerning the value of various compounds of caffeine. The author used caffeine and the salts of sodium, the benzoate and the salicylate. He arrives at the following conclusions:

In valvular affections of the heart the caffeine fulfils the indication of compensating for insufficiency, in many cases being equally valuable with digitalis and strophanthus. Under its influence the œdema is absorbed and the excretion of urine increased. The rhythm of the heart is also improved. The author administers caffeine whenever the lesions resulting from the cardiac failure are sufficiently advanced to produce passive congestion of the liver, of the kidneys, or when it is associated with chronic interstitial nephritis. Under such circumstances the left ventricle is often hypertrophied, and so compensation is completed. Where the œdema of the extremities is marked and the urine is scanty, caffeine is particularly useful, acting when digitalis is without effect, as it regulates the circulation, increases renal secretion, and so causes disappearance of the œdema. In cases of chronic myocarditis, fatty degeneration of the heart, and sclerosis of the coronary arteries it may do some good, but particularly in myocarditis is it serviceable. Caffeine is also useful in very acute insufficiency, such as occurs during the course of acute infectious diseases;

particularly is it useful in shock or collapse with disappearance of the radial pulse and cyanosis of the extremities, as it stimulates the vaso-motor centre and so causes an equal distribution of the blood-supply. The preparation of caffeine which Pavinsky most frequently employs is the benzoate of sodium and caffeine, which he gives in the dose of 2 to 4 grains in a cachet, often giving as much as six to eight cachets in a day; or he gives the following combination:

R Caffeine benzoate of sodium, gr. iv;  
Powdered digitalis leaves, gr. i;  
Powdered camphor, gr. vi;  
White sugar, gr. iv.

Put up into one cachet, and 3 to 6 of these cachets to be given in a day.

The total doses of these caffeine preparations which he recommends are 20 grains of caffeine benzoate of sodium, or 25 grains of the caffeine salicylate of sodium, or 8 to 15 grains pure caffeine.

In cases where the first sound of the heart is feeble and collapse is present the following prescription may be given subcutaneously:

R Caffeine benzoate of sodium, ʒi;  
Distilled water, ʒvi.

10 to 20 minims of this solution hypodermically.

Or,

R Caffeine salicylate of sodium, gr. xlv;  
Distilled water, ʒvi.  
10 to 20 minims hypodermically.

Should the symptoms be very urgent, several syringefuls may be injected. Should the administration of caffeine by the mouth produce irritability of the stomach, he employs the following prescription by suppository:

R Caffeine benzoate of sodium, ʒi;  
Cocoa butter, q. s.

Make 2 suppositories; give 2 to 4 of these a day.

#### PRESCRIPTIONS.

In cases of anæmia:

R Ferri reducti,  
Pulv. camphoræ, of each, ʒiss;  
Ext. gentianæ, ʒi;  
Mucilaginis acaciæ, q. s. M.

To make ninety pills; 2 or 3 may be taken thrice daily.

A new treatment for pertussis:

R Hydrarg. perchlor., gr. i;  
Aq. destill., ad ʒiv. M.  
Label for external use.

A small tampon of cotton-wool is dipped in the solution, and then the base of the tongue, the epiglottis, and the mucous surfaces adjoining are freely swabbed therewith. In slight cases of pertussis this treatment may be practised once a day, but in grave cases twice in twenty-four hours.

A useful hepatic stimulant :

R Euonymin, gr. ii;  
Pil. colocynth. comp., gr. ii;  
Ext. hyoscyami, gr. ss. M.

To form one pill; 1 or 2 to be taken at bedtime.

For hæmoptysis :

R Pulv. ergotæ,  
Pulv. extracti krameriæ, of each, ʒi;  
Extracti belladonnæ, gr. v;  
Pulv. digitalis, gr. x. M.

To make forty pills; from 4 to 6 to be taken for a dose.

The patient must keep quiet, lying in bed, with heat to the extremities, and be given pieces of ice to suck.—*Medical Press and Circular*, May 2, 1894.

#### THE EMPLOYMENT OF CAFFEINE IN CHILDREN.

The *Bulletin Générale de Thérapeutique* for May 15, 1894, contains an abstract in which the value of caffeine in the treatment of children is emphasized, particularly in those diseases which are accompanied by a feeble circulation, such as typhoid fever, pneumonia, and diphtheria, or the congestion of the lungs which is so apt to occur with the infectious diseases. It is believed that the drug prevents the collapse and syncope which may occur after the use of a cold bath. If such an accident should be threatened, a hypodermic injection of the caffeine should be given. Perhaps the best way to administer the caffeine by the mouth is as follows :

R Caffeine, gr. xx;  
Benzoate of sodium, gr. xx;  
Vanillin, gr. i;  
Syrup of tolu, ʒii;  
Rum, ʒiii;  
Water, ʒiii.

2 teaspoonfuls once, twice, or thrice a day.

#### PRESCRIPTIONS.

For tic douloureux :

R Ammonii chloridi, gr. xx;  
Butyl chloral hydratis, gr. v;  
Glycerini, ℥x;  
Aquæ chloroformi, q. s. ad ʒss.  
Misce et fiat haustus.

To be taken every two hours till three doses have been taken.

An ointment for acute rheumatic arthritis :

R Acidi salicylici,  
Adipis lanæ hydrosi, of each, ʒi;  
Olei terebinthinæ, ʒi;  
Adipis benzoati, ad ʒi.  
Misce et fiat unguentum.

To be frequently well rubbed into the affected parts.

Subcutaneous injection for hemorrhoids :

R Acidi carbolic, ʒiss;  
Acidi salicylici, ʒss;  
Sodii biboratis, ʒi;  
Glycerini, ad ʒi.

Misce et fiat injectio hypodermica.

2 to 4 minims to be injected slowly into the base of the hemorrhoid.

A depilatory pigment :

R Iodi, gr. xii;  
Olei terebinthinæ, ℥xx;  
Olei ricini, ʒss;  
Spiritus rectificati, ʒliiss;  
Collodii, ad ʒi.  
Misce et fiat pigmentum.

To be applied daily for three days.

—*Practitioner*, May, 1894.

#### BENZINE-POISONING AND THE ABUSE OF BENZINE.

After referring briefly to the cases of benzine-poisoning reported by Kobert, Koppel, and Falk, DR. ERNST ROSENTHAL (*Centralblatt für Innere Medizin*, No. 13, 1894) reports a case which came under his care. A year-and-a-half-old child drank perhaps a teaspoonful of benzine from a bottle. Rosenthal saw the child about fifteen minutes later, when it was in a state of stupefaction. When the skin was irritated, it roused and struggled and cried, but as soon as it was let alone it subsided again into the former state. Rosenthal promptly withdrew the contents of the stomach, which consisted of particles of milk and flakes of bloody-colored mucus, and smelled strongly of benzine; then he washed out the stomach, finding more bloody mucus. At first the symptoms of poisoning seemed to become more intense; after about an hour they reached their height. At this time the pulse was at times not perceptible in the radial artery; respiration had become somewhat more frequent and was accompanied with a rasping sound. The child's breath smelled strongly of benzine. Mostly the child lay quiet in narcosis, occasionally rolling about and in danger of falling from the bed; sometimes it clutched its body and distorted its face with pain. The pulse rose gradually, the skin became warm, a profuse perspiration occurred, and apparently the child fell into normal sleep.

On the evening of the same day, six hours after the poisoning, the child was still slightly stupefied, was weak, could not stand up, but staggered; the respiration was still above normal; the urine passed that evening was free from albumin and sugar. Rosenthal ordered an enema, and it was followed by a passage which contained bloody flakes of mucous membrane. The next morning the child was perfectly well again.

Rosenthal had one patient who had the "benzine habit;" he had formerly been addicted to alcohol, and found the benumbing produced by smelling benzine a complete substitute for alcohol.

#### PRESCRIPTIONS.

An application for enlarged glands:

R Iodoformi,  
Bals. Peruviani, of each,  $\mathfrak{z}\text{i}$ ;  
Collodii,  $\mathfrak{z}\text{i}$ . M.

To be painted over the swellings every night.

For urticaria:

R Liq. calcis,  
Aq. lauro-cerasi,  
Glycerini, equal parts. M.

The skin is dabbed with some of the lotion, and then covered with a thin layer of cotton-wool.

For fetid diarrhoea in children:

R Calomel, gr. iss;  
Zinci sulpho-carbolatis,  $\mathfrak{z}\text{iiss}$ ;  
Bismuthi subnitratris,  $\mathfrak{z}\text{ii}$ ;  
Pepsinæ, gr. xxx. M.

Divide into twenty powders; 3 powders daily for a child of one year.

For laryngeal phthisis:

R Iodoformi,  $\mathfrak{z}\text{i}$ ;  
Pulv. acid. borici, gr. vii;  
Pulv. calcii phosph.,  $\mathfrak{z}\text{iiss}$ . M.

Morning and evening the throat should be insufflated with the powder, which must be extremely fine.

A mixture for asthma:

R Chloroformi,  $\mathfrak{z}\text{i}$ ;  
Ætheris,  $\mathfrak{z}\text{iiss}$ ;  
Syr. acaciæ,  $\mathfrak{z}\text{i}$ ;  
Tinct. cardamomi co.,  $\mathfrak{z}\text{i}$ . M.

A teaspoonful to be taken every half-hour until relief is obtained.

Pills for chronic bronchitis:

R Ammonii chloridi, gr. xv;  
Ammon. carb., gr. xv;  
Pulv. ipecac., gr. iii;  
Morph. hydrochloratis, gr. i;  
Mucilaginis acaciæ, q. s. M.

Divide into ten pills; 1 to be taken night and morning.

—*Medical Press and Circular*, May 9, 1894.

#### ON A NEW TREATMENT OF DIPHTHERIA AND PSEUDO-MEMBRANOUS LARYNGITIS.

PIEDALLU (*Les Nouveaux Remèdes*, March 24, 1894) claims to have been successful in the treatment of diphtheria and pseudo-membranous laryngitis without resorting to surgical interference. Since 1891 he affirms to have treated these cases without a single death. He employs the following combination, which is a modification of Gibert's syrup:

R Simple syrup, 1000 grammes ( $33\frac{1}{3}$  ounces);  
Iodide of potassium, 50 grammes ( $1\frac{1}{2}$  ounces);  
Biniodide of mercury, .50 gramme (8 grains).

The author administers this mixture in tea- or dessertspoonfuls every two hours, according to the age of the child. He has given as much as three hundred grammes (ten ounces) of the iodo-mercurial syrup in from six to eight days to children of from four to six years of age. In a few hours after the ingestion of the remedy, the symptoms of iodism, such as coryza, insalivation, etc., appear; the dose is then diminished, but a condition of saturation is maintained. An antiseptic gargle is likewise recommended. Twice or three times a day the false membranes are raised carefully with the handle of a spoon and touched with a tampon charged with Van Swieten's liquid. The good results are obtained in about forty-eight hours. In rebellious cases such results are not observed before the fourth or the fifth day of treatment, but the administration of the syrup is continued, in doses proportionate to the gravity of the disease. This form of medication is well borne by children. No colicky pains, vomiting, or stomatitis have been observed. If the patient exhibits gastric disturbances, ipecacuanha is administered. Special attention should be paid to the condition of the bowels. A milk diet is advised. The kidneys must be kept active, and as soon as the child is able to eat, light articles of food are allowed. The author energetically protests against the use of any alcoholic medication.

#### A PRESCRIPTION FOR INTERMITTENT FEVER.

R Salicylate of quinine, gr. xx;  
Syrup of orange,  $\mathfrak{z}\text{ii}$ ;  
Rum,  $\mathfrak{z}\text{ii}$ ;  
Simple syrup,  $\mathfrak{z}\text{iii}$ .

A dessertspoonful every hour for eight hours prior to the attack in quotidian fever, twelve hours prior in tertian fever, and fifteen hours before the attack in quartan fever.

—*Journal de Médecine de Paris*, May, 1894.

## TREATMENT OF EPILEPSY.

In the *Journal de Médecine de Paris* for May 13, 1894, there is an article upon this subject, in which the treatment is given as follows:

For the prevention of an attack, intellectual fatigue should be avoided, as should also rapid changes of temperature and exposure to great heat or cold. The use of alcohol and coffee in large amounts at meals is to be prohibited. During the attack care is to be taken that the patient does not injure himself, and should any tendency to repetition of the attack occur the following rectal injection should be given:

R Chloral,  
Bromide of potassium, of each, gr. xxx;  
Yolk of egg, 1;  
Water, ℥viii.

Should the epilepsy be traumatic in origin, surgical interference should be resorted to. Care should be taken not to confound traumatic epilepsy with that due to syphilis. If the latter is the cause of the disease, mercurial inunctions and intramuscular injections should be resorted to.

Between the attacks the patient should receive nerve sedatives. The following is a useful formula:

R Bromide of potassium, ℥vi;  
Phosphate of sodium, ℥vi;  
Syrup of bitter orange, ℥i;  
Wine, ℥x.  
Tablespoonful after each principal meal.

Should the epileptic attacks occur at the menstrual periods, it is well to administer the following powder in cachet:

R Antipyrin, gr. viii;  
Bicarbonate of sodium, gr. ii.

If the pulse is feeble and the circulation is poor, the following may be used in a cachet:

R Powdered digitalis, gr. i;  
Bicarbonate of sodium, gr. v.

In other instances it is well to administer, with the bromide, hyoscyamine as follows:

R Bromide of potassium, ℥i;  
Bromide of sodium,  
Bromide of ammonium, of each, ℥ss;  
Crystallized hyoscyamine, gr. ʒi;  
Water, Oii.

A tablespoonful to a wineglassful three times a day, or oftener if needed.

Should evidences of bromism occur, it will be found that the bromide of gold is well borne, and the following may be ordered:

R Bromide of gold, gr. iv;  
Water, Oii.

A tablespoonful twice or three times a day.

Sometimes it is well to administer the bromides in beer or milk to mask the taste. In some special cases of epilepsy, borax, in 5- or 10-grain doses, is useful.

## WASHING OUT THE LARGE INTESTINE WITH OIL.

According to JULIO ROBERT (*Revista de Medicina y Cirugía Prácticas*, No. 419; *Rev. Internation. de Bibliograph. Médicale*, March 25, 1894), Chercheffsky's method of washing out the large intestine with oil consists: 1. In introducing a Nélaton rubber sound through the anus and as far inward as the valve of Bauhin. 2. In injecting by means of this sound a Russian pound, or 407 grammes (13 ounces and 1 drachm) of olive oil at a temperature of 100.4° F. (38° C.). The patient is placed on the side and the sound introduced, the oil being poured in from a height of about twenty-four inches (sixty centimetres). The oil must in every case be injected in a slow manner. The method is of general application in cases of constipation. The fecal matters, expelled at about twelve hours after the operation, are abundant and of a fetid odor. The evacuation can be hastened by the administration on the following day of a glassful of some saline purgative water. The intestinal washing should be made preferably four hours after the evening meal. The author details four cases treated by the above method, and suggests a similar treatment in all cases where symptoms of auto-intoxication, due to intestinal fermentation, are present.

## HOW TO PRESCRIBE CERTAIN REMEDIES.

In an interesting article upon the art of prescribing medicines, DUJARDIN-BEAUMETZ (*Bull. Génér. de Thérapeutique*, March 30, 1894) calls attention to the advantages and disadvantages of certain remedial combinations intended for external use. Referring to antiseptic solutions, he believes that the antiseptic properties of corrosive sublimate, for instance, are strengthened by the addition of tartaric acid, as in the following mixture:

R Corrosive sublimate, 1 gramme (15 grains);  
Tartaric acid, 5 grammes (75 grains);  
Boiled distilled water, 1 litre (1.7 pints).

A combination which, according to Salomon, guards against poisoning by the sublimate is as follows:

- R Corrosive sublimate, 1 gramme (15 grains);  
Tartaric acid, 5 grammes (75 grains);  
Chloride of sodium, 1 gramme (15 grains);  
Sulphate of copper, 2 grammes (30 grains);  
Boiled distilled water, 1000 grammes (32.1 ounces).

Boric acid is also largely used, not so much on account of its antiseptic properties as owing to its innocuousness. It is recommended in the strength of 3 to 1000, or, like the bichloride, it may be employed in such mixtures as the following:

- R Boric acid, 25 grammes (6¼ drachms);  
Phenic acid, 1 gramme (15 grains);  
Thymol, .30 gramme (5 grains);  
Alcohol to dissolve, q. s.;  
Boiled distilled water, 1000 grammes (32.1 ounces).

Thymol, considered as an excellent antiseptic, is best combined as follows:

- R Thymol, 1 gramme (15 grains);  
Alcohol at 85° F., 4 grammes (1 drachm);  
Distilled water, 995 grammes (31 ounces).

For the medication of baths some combinations are recommended. For an alkaline bath, for instance, the following formula may be used:

- R Crystallized trisulphate of sodium, 60 grammes (2 ounces);  
Crystallized chloride of sodium, 60 grammes (2 ounces);  
Carbonate of sodium, 30 grammes (1 ounce).

Where the use of corrosive sublimate becomes necessary, either of the two following mixtures may be employed:

1. R Bichloride of mercury, 20 grammes (5.4 drachms);  
Alcohol at 90° F., 50 grammes (1 ounce, 5.4 drachms);  
Distilled water, 200 grammes (6.76 ounces).
2. R Bichloride of mercury, 15 grammes (4.16 drachms);  
Chlorhydrate of ammonium, 15 grammes (4.16 drachms);  
Distilled water, 500 grammes (16.90 ounces).

#### THE ABSORPTION OF GUAIACOL THROUGH THE SKIN.

G. LINOSSIER and M. LANNOIS (*Lyon Médical*, April 1, 1894) publish the details of a series of experiments carried on to determine the cutaneous absorption of guaiacol. From the results obtained in the experiments described the authors draw the following conclusions:

1. Guaiacol, locally applied, is absorbed by the skin.

2. The absorption is very rapid, the remedy appearing in the urine fifteen minutes after its application. The proportion of guaiacol in the urine increases gradually, reaching its maximum in from one and a half to one and three-quarters hours. The elimination is almost complete in twenty-four hours.

3. In the total urine of twenty-four hours the proportion of guaiacol recovered has been 55.5 per 100, when the amount of the drug used has been from 2 to 4 grammes (30 to 60 grains). The absolute quantity of guaiacol recovered from the urine after an application of 4 grammes was 2.2 grammes (34 grains); in another instance, 3.3 grammes (50 grains), after an application of 10 grammes (2.58 drachms).

4. The cutaneous absorption is so pronounced that the organism may be saturated with guaiacol without having to resort to the ingestion of the drug by the mouth or subcutaneously.

#### THE ACTIONS OF CHLORIDE OF METHYLENE, CHLOROFORM, AND TETRACHLORIDE OF CARBON.

The above substances have been studied experimentally by J. F. HEYMANS and D. DEBUCK (*La Presse Médicale Belge*, April 1, 1894). They find that all those agents increase, in the rabbit, the elimination of urea, of phosphates, and of chlorides. The authors believe that the three substances enhance the activity in the secretion of urea, phosphates, and chlorides in the tissues themselves. This action is made manifest with a rapidity proportionate to the toxicity of each one of the agents under consideration.

#### THE TREATMENT OF CHRONIC INTERMITTENT FEVER.

In a communication, SPIRIDION KANELIS, of Athens (*Bull. Génér. de Thérapeutique*, April 15, 1894), recommends the following line of treatment in cases of chronic intermittent fever. The patient is advised to take every morning four pills of the following combination:

- R Sulphate of quinine, 11.25 grammes (2.81 drachms)  
Arsenate of sodium, .03 gramme (½ grain);  
Extract of cinchona, q. s.  
M. and make thirty pills.

The four pills are to be taken for two weeks without interruption; they are then stopped for a week, to be resumed for a second period of two weeks, and so on during a course of three months. At the same time, the patient must

take twice a day, at noon and at night, and without interruption, during the three months of treatment, before meals, a cup of this mixture :

- R Bark of royal cinchona, .30 gramme (5 grains);  
Absinthe herb, .30 gramme (5 grains).  
For an infusion the quantity of which should be  
700 grammes (21.8 ounces),  
Dry extract of cinchona, 3.75 grammes (2.81  
scruples);  
Cognac, 60 grammes (2 ounces).

In the morning, two hours before taking the pills, the patient is to take a glass of milk. At noon the meal should consist of strong bouillon, beefsteak, eggs, and old wine; the same *régime* at night, and the patient should get to bed as soon after this last repast as possible. The author affirms to have treated five hundred and twenty patients, using the above method, in the course of ten years, with the most excellent results.

#### TRIONAL.

K. RYCHLINSKI (*Kronika Lekarska*, February, 1894) tried trional in fourteen cases of sleeplessness in neurotic or insane subjects, in doses varying from .5 to 4 grammes. The total number of observations amounted to one hundred. In several cases he carried out comparative experiments with other hypnotics (sulphonal, chloral hydrate, sulphate of dyboisin). He found that,—

1. Trional acts admirably, especially in cases of insomnia due to functional disturbances in the nervous system.
2. It does not affect in the least the cardiac action, even when heart-disease is present.
3. It has no bad taste and is easily soluble in hot tea or milk.
4. The patient awakens without any disagreeable sensations about the head.
5. The sleep-giving dose is smaller in comparison with other drugs of the kind.
6. On the whole, trional should be preferred to all our ordinary hypnotic remedies.—*British Medical Journal*, April 21, 1894.

#### THE TREATMENT OF NEPHRITIC COLIC.

In *L'Union Médicale* for March 31, 1894, the following advice is given in regard to the treatment of this condition. The pain is to be relieved by a hypodermic injection of morphine, and a large hot bath given every hour or hour and a half during the day. The patient is to be nourished by soups and con-

centrated foods, and should drink large quantities of Vichy and other mild alkaline waters, but cold milk and frozen champagne are not to be taken. Hot applications of counter-irritants should be applied to the abdomen and hypogastrium, and it may be well to administer a few drops of spirit of chloroform, or, should the pain become excessive, inhalations of chloroform or ether through the first stage of anaesthesia may be practised. If the stomach will stand it, morphine and belladonna may be given. In other cases, in addition to the treatment which has been named, and between the attacks, it is well to administer 8 grains of benzoate of lithium at each meal, the same quantity of salol, or a teaspoonful of the following mixture, chloroform being supposed to have a distinct antilithæmic influence :

- R Chloroform-water,  $\overline{\text{z}}$ iii;  
Syrup of oranges,  $\overline{\text{z}}$ ii.  
A tablespoonful after each meal.

The food should consist between the attacks of white meats, salads, artichokes, salsify, celery, milk, red and white wines, which should be dry, and a mild alkaline mineral water. The fresh fruits are also advisable, and the grape- or raisin-cure is useful. Of the foods to be avoided we find tomatoes, asparagus, peas, beans, all alcoholic drinks which contain much sweets or much gas. We may allow in very small quantities cold meats, eggs, fish, crabs, potatoes, and a very small quantity of bread. The patient must be told to masticate his food thoroughly, and to drink before going to bed large quantities of Vals water or that of Contrexéville, or, for that matter, any pure water which will dissolve effete materials. Constipation should be avoided, and the garments should be so made as to avoid taking cold. Every morning a small teaspoonful of powdered Rochelle salt in water may be used. The bladder should be frequently emptied. Exercise is very useful, such as walking or gymnastics. Should the patient perspire freely, he must be carefully rubbed dry after the exercise is over, and every morning should take a sponge-bath, followed by hard friction with a rough towel. Alkaline baths should be taken at least two or three times a week. The internal medication between the attacks should consist not only in the use of benzoate of lithium, in the dose of 20 grains a day in one or two doses, but an active diuretic treatment should be instituted. For the production of a general alkaline influence bicarbonate of sodium may be freely taken, or the following employed :

R Bicarbonate of sodium, gr. xxx;  
 Powdered tartaric acid, gr. xv;  
 Calcined magnesias, gr. x.  
 Make into one powder and take after meals.

Should there be gravel due to oxalates, the patient must avoid foods which are rich in oxalic acid, such as tomatoes and rhubarb, and we should administer 15 grains of phosphate of sodium after each meal and on going to bed at night. In those cases where concentrated meat soups have been taken and a condition of oxaluria produced, the patient should be obliged to give this up and to rely chiefly upon milk and eggs for nourishment.

#### A NEW TREATMENT FOR DIPHTHERIA.

BIANCHINI (*Gazz. degli Ospitali*, March 20, 1894) describes a method of treating diphtheria, which consists in the local application to the neck of the patient of fomentations moistened with a two-per-cent. solution of carbolic acid in lead lotion, these being applied at as early a stage as possible, with the idea of acting on the micro-organisms of the local lesions, and thus preventing their further spread. Application in this way secures the absorption of the phenol, both through the skin, which appears to be easy in the case of children, and also in the form of vapor through the mouth. This has been supplemented in the most serious cases by painting the pharynx, etc., with the following pigment:

Salicylic acid, 45 grains;  
 Absolute alcohol, 6 drachms;  
 Resorcin, 30 grains;  
 Glycerin, 3 drachms.

To be applied two or three times daily.

The result has been very satisfactory. Out of forty-five cases of varying severity, the duration of treatment varied from six to eighteen days on an average, but in one case was as long as thirty days. To these forty-five cases are appended notes of nine others treated by other practitioners, in every case successfully. —*British Medical Journal*, May 5, 1894.

#### TREATMENT OF ATONIC GASTRIC DILATATION.

WEGELE (*Münch. Med. Woch.*, March 28, 1894) deals with the severer forms of this disease, and not with such as accompany any gastric affection lasting over any considerable time. For the practical distinction of mild from severe cases the test breakfast is useful: in marked cases remains of food are found in

the water used for washing out the stomach on the following morning, whereas in mild cases the stomach is able to deal with such moderate demands. Pronounced atonic dilatation is not, in the author's opinion, such a rare event as is sometimes represented. At first the dry diet was employed, and for slighter cases it sufficed; but a rigorous carrying out of this regimen was often of disadvantage. Washing out the stomach proved a great advantage, as in this way the stomach was freed of very acid and fermenting contents. Here, however, a considerable amount of nourishment is withdrawn, and the patient's nutrition and weight may suffer. Rectal alimentation must, in addition, be had recourse to; either water alone or the desirable food-stuffs may be thus used. The amount of urine passed is a practical measure of the gastric insufficiency. By a strict dry diet and supplying the necessary water by the rectum, the patient's condition may be very greatly improved. Clysters containing grape-sugar are apt to ferment and to produce diarrhoea, and the same is true of those containing peptone, frequently repeated. The diet must be suited to the condition of the gastric chemistry. If hyperacidity is present, large doses of alkalies are indicated. Washing out the stomach is, according to the author, best done in the morning. Raising the foot of the bed is said to be useful in helping to empty the pyloric antrum. If fermentation is present, harmless antiseptics should be added to the water, and salicylic acid, creosote, and bismuth salicylate given internally. If the abdominal walls are lax, a belt should be used. The author says that the prognosis is considerably improved by the use of the dry diet and supplying fluid by the rectum.

#### THE EXTRAORDINARY EFFECTS OF A LARGE DOSE OF HYOSCINE.

In the March number of the *Indian Medical Record*, ASSISTANT SURGEON BALAGOPAL, L.M.S., relates the case of a man, fifty years old, who was an inmate of the Chhatrapur Hospital, suffering from mania. For twenty-five years he had had maniacal attacks, each of which lasted at least a month, after which he gradually recovered his sanity and remained quite sane for six or seven months. He had been treated by various eminent physicians, but only with the result of tempering the violence of his maniacal paroxysms; the attacks continued to occur twice a year. At last, after having been forced to retire from his work as a post-office employee, he had asked the author to treat him, remarking that life was a burden, and that he would

rather poison himself than suffer any longer from his dreadful disease. Two or three days after this a severe attack of maniacal delirium occurred, and the author tried divers sorts of nervine, sedative, and antispasmodic medicines, together with the use of plasters, blisters, and setons, but all proved of no avail. As a last resort he gave the patient a hypodermic injection of  $\frac{1}{6}$  grain of hyoscine hydrobromide. In two or three minutes after the injection the patient fell down prostrate upon the ground and cried out that he was dying. His face became deadly pale and the conjunctivæ insensitive. The pupils were extremely dilated, the breathing was very difficult and stertorous, the limbs were contracted spasmodically, the pulse was very weak and compressible, and the temperature was subnormal. The author, being very much alarmed at the man's condition, hastened to his bookcase to ascertain the proper dose of the medicine, and, to his utter dismay, found that it was from .03 to .01 grain, while he had given  $\frac{1}{6}$  grain. Feeling that he had unwittingly poisoned the poor maniac, he began to stimulate him by means of hypodermic injections of 20 minims of sulphuric ether every half-hour. After the third injection the spasms were seen to diminish in frequency and in strength, and after the fourth they ceased, the conjunctivæ responded to the touch, and the breathing became a little easier; at the same time the color was seen to return to the man's face. In half an hour after the fifth injection the man tried to open his eyes and to speak; after this he improved gradually and recovered consciousness in five or six hours after he had received the dose of hyoscine. After this the patient improved day by day, and in the course of a week he was of sound mind, and had since shown no signs of cerebral trouble.—*New York Medical Journal*, April 28, 1894.

#### A PRESCRIPTION FOR ULCERATION OF THE STOMACH.

In the *Journal de Médecine de Paris* for March 6, 1894, the following prescription is given for cases of chronic gastric ulcer:

- R Chloroform,  $\mathfrak{m}\text{xv}$ ;  
 Subnitrate of bismuth, gr.  $\text{xlv}$ ;  
 Distilled water,  $\mathfrak{z}\text{iv}$ .  
 1 to 2 teaspoonfuls every hour or two.  
 Shake well before taking.

If the case is severe and there is much gastralgia this prescription is particularly useful for the relief of the pain.

#### GAVAGE.

HOLT, of New York, writes an article on this subject in the *New York Medical Record* for April 28, 1894.

The technique of gavage is very simple. The ordinary apparatus used for stomach-washing is all that is required,—viz., a funnel, eighteen inches of rubber tubing, a soft-rubber catheter, and a few inches of glass tubing for connection. The catheter should have a double eye; No. 14, American scale, is the best size for infants under six months, and about No. 17 for older children; a 4-ounce funnel is large enough for infants, while for older children it is an advantage to use one holding six or eight ounces. The child is placed flat upon the back in its crib, and the head steadied by an assistant. The tongue is depressed with the left forefinger, and the catheter, previously oiled, is pushed rapidly down the pharynx until nine or ten inches have passed the lips. The funnel is now raised high in the air for a few moments to allow gas from the stomach to escape. The food is poured into the funnel and rapidly runs into the stomach. As the last of the food leaves the funnel the catheter is tightly pinched and quickly withdrawn. This last step is an important one, in order to prevent trickling of food in the pharynx, which may provoke vomiting. Sometimes the food remains in the funnel and will not run into the stomach. This is not ordinarily from blocking of the eye of the catheter by mucus, but from gas in the tube. In a few moments this generally rises to the surface of the liquid, and then the food flows readily. If regurgitation of the food takes place, it is generally immediately after withdrawing the tube. In many cases it may be prevented by allowing the gas to escape from the stomach before putting the food in, and in others by holding the jaws separated for a few moments after the catheter has been withdrawn.

In young infants no gag is required, but in older children one is quite necessary, since otherwise they may bite the catheter in two. Where a gag is needed, the ordinary one accompanying intubation sets will answer the purpose. Two assistants are usually required to feed an older child. It is important that the child should be held flat upon its back.

The time consumed in feeding by gavage is from ten to thirty seconds. In infants this is very easily done. In the institutions referred to all the nurses have been taught to do it, and they learn, with very little experience, to do it very quickly.

The uses of gavage may be briefly stated as follows:

1. In premature infants its value has been well established on the continent of Europe, in connection with the use of the incubator. As yet we have had but little experience with it in this country.

2. It is useful in controlling persistent vomiting in very young infants, where the vomiting occurs partly from habit and partly from exaggerated pharyngeal reflex. Dr. Kerley's published paper established this point conclusively, and subsequent experience has confirmed his observations. Dr. R. B. Kimball, attending physician to the Summer Branch of the Babies' Hospital, is soon to publish a large number of cases treated in the summer of 1893, also confirmatory of this point.

3. In acute diseases where, for any reason, children refuse all food, or struggle violently against everything that is offered them. In very many cases of severe illness in children from two to five years of age, the point is reached, after four or five days have passed, when the child absolutely refuses to take anything, and nothing is got down excepting by holding the nose. This is one of the most promising fields for the application of gavage. In very severe cases of scarlet fever, diphtheria, broncho-pneumonia, typhoid, and empyema just this necessity is felt.

4. In serious brain-disease where the patient cannot be fed by ordinary means. This may occur in tubercular meningitis, chronic meningitis, and in many other diseases where delirium or coma is a symptom. Life is not only prolonged, but existence made more tolerable, and the patient is much more easily cared for by the attendants.

#### *PERSISTENT SNEEZING UNDER CHLOROFORM ANÆSTHESIA.*

In the *Indian Medical Gazette* for April, 1894, CHALKE reports the case of a well-proportioned Hindoo male, aged thirty-four years, who was admitted into the Berhampoor Municipal Hospital as an in-patient, suffering from complete staphyloma of the right cornea with disorganization of the eyeball, requiring extirpation. He had, besides, granular lids of the same eye of some years' standing.

As it was decided to remove the eyeball, the patient was placed on the operation-table and chloroform administered. When he was completely anæsthetized, the district surgeon adjusted the stop speculum into the affected eye.

Almost immediately this was done the pa-

tient began sneezing persistently for a couple of minutes and recovered consciousness. In the mean while the speculum had to be removed. The patient was again chloroformed, and when completely under its effects the stop speculum was again adjusted, when the sneezing reappeared, the patient recovering consciousness as before. For the third and last time the inhalation was repeated, when the same events occurred on adjusting the speculum. As he had already inhaled a large quantity of chloroform, it was thought advisable to postpone the operation to a subsequent date. After the lapse of four days he was a second time placed on the operation-table and chloroform was administered, a hypodermic injection of  $\frac{1}{2}$  grain of cocaine having been previously given. He was very quickly anæsthetized, and the speculum being adjusted, the sneezing commenced again and the man recovered consciousness. He was again chloroformed, but on this occasion a four-per-cent. solution of cocaine was dropped into the affected eye at frequent intervals as a local anæsthetic. When completely narcotized the stop speculum was adjusted, but no sneezing occurred, and the operation was performed without any further trouble.

When the patient was chloroformed on the first occasion (three times), it was puzzling to discover the cause of sneezing, especially when the patient was completely anæsthetized,—a stage when all reflex actions are temporarily abolished; but on carefully judging the time of the occurrence of the sneezing, soon after the adjustment of the speculum, the idea of combining the effects of cocaine as a local anæsthetic suggested itself, which was adopted only on the second occasion, but not until there had been a repetition of the sneezing as on the first occasion. The cocaine had the desired effect of deadening the morbid sensibility of the eye and stopping reflex action.

In order to illustrate the physiological action of sneezing in this particular instance, the author explains briefly how this most probably occurred.

It has been stated that the eyeball was chronically affected for some years from granular conjunctivitis and complete staphyloma of the cornea; consequently the sensory nerves of these structures must have participated in the inflammatory process and became hyperæsthetic. The distribution of these nerves is briefly as follows:

The nasal nerve,—a branch of the ophthalmic,—as it passes the inner side of the orbit, gives off three branches—the long and short ciliary and the infratrochlear—which supply

sensation to the cornea, sclerotic, conjunctiva, and the integument of the side of the nose.

The nasal nerve then passes through the shallow groove in the cribriform plate of the ethmoid, and divides into an internal and external branch, supplying the mucous membrane and integument of the nose with sensation. It therefore appears that the irritation caused by the pressure of the speculum on the hypersensitive nerve-filaments must have been transmitted to the nose by the nasal nerve, and excited the persistent sneezing so characteristic in this case, just in the same manner as the sun's light falling strongly on the eye produces a tickling in the nose.

The next question which naturally suggests itself is, Why should reflex action occur when the patient is completely anæsthetized? To explain this particular point the following is quoted: "All parts of the body do not become insensible in equal times; certain portions of the skin and subcutaneous tissue retain their sensibility with extraordinary tenacity; these are the matrix of the great toe-nail, the margin of the anus, and the whole of the skin of the organs of generation. It is impossible to obliterate their sensibility without pushing chloroform to a degree which greatly surpasses that required for ordinary purposes."

As mentioned previously, the patient was perfectly anæsthetized and the conjunctivæ and cornæ insensible to the touch of the finger, and the man was, for all ordinary purposes, sufficiently narcotized for the operation; but owing to the hyperæsthetic condition of the nerves of the eye, reflex action was not completely annihilated, and the speculum being of a hard nature, pressing forcibly on the nerves excited the sneezing, so singular in this case.

#### ACTION OF STRYCHNINE ON THE PANCREAS.

D. N. AGRICOLANSKY made twelve experiments on four dogs with an artificial pancreatic fistula, which show that,—

1. When given in considerable doses, nitrate of strychnine markedly inhibits the pancreatic secretion, the latter finally ceasing altogether in from ten to thirty minutes after the administration; subsequently, however, the inhibitory effects slowly cease.

2. Smaller doses either produce no impression whatever, or may even slightly increase the secretion.

3. There is no definite correlation between a general physiological action of the drug and its inhibitory influence on the gland.

4. Qualitative changes of the juice are but slight and inconstant, and, when present, seem to be caused rather by alterations in the concentration of the juice than by the action of the drug on the formation and secretion of the pancreatic ferments.

5. In the presence of small quantities of strychnine in the juice, saccharification of starch proceeds more extensively than under the ordinary conditions, while the proteid digestion remains unaltered. When present in a large proportion, the drug retards the digestion. —*British Medical Journal*, April 7, 1894.

#### PERMANGANATE OF POTASSIUM AN ANTIDOTE TO MORPHINE.

HARDING contributes his ideas on the chemical side of this question to the *New York Medical Record* of April 14, 1894, in which he says that the observations made by Dr. Moor, to hold a 1 to 2000 solution in his mouth for fully five minutes without any serious deoxidation of the permanganate of potassium, is no criterion of its non-decomposition in the buccal cavity or its connecting parts, for alkaline properties, or an alkalinity of the contents of any cavity, favor the non-decomposition, and the decomposition of the permanganate in an alkaline fluid proceeds but very slowly. A test-tube full of water (which contained soluble organic substance) which had been made alkaline, and to which had been added a few drops of solution of permanganate of potassium, did not begin to discharge its color for nearly an hour. Acid solutions favor the decomposition of the permanganate, and the advice to give an acid of some kind in case of opium-poisoning, or in case of any of the salts of morphine, and vinegar being advised by Dr. Moor, is erroneous beyond measure; for do not text-books teach, and experience has proved, that acetic acid especially decomposes permanganate?

The action of the permanganate upon albumin and peptone is a criterion only so far as they go, for the stomach usually contains starches, etc., in addition to albuminoids and peptones; starches especially decompose the permanganate quickly; raw starch has but little action upon it, but boiled starch in any form quickly demands its attention. We may say that people do not eat much boiled starch. This idea is, however, quite erroneous, for potatoes and bread contain a large amount of starch, which is only partially acted upon by the alkaline secretion of the mouth during mastication; it lies dormant in the acid fluid

of the stomach, but is converted and absorbed in the small intestines; this starch, also, while it lies dormant in the stomach, quickly attacks the permanganate. Were nothing to interfere, 1 grain of permanganate of potassium would be able to oxidize more than 1 grain of morphine, so almost anything, if taken in doses large enough, may prove an antidote for morphine. Now, suppose the morphine has entered into the circulation, would this still be counteracted by the permanganate? The advocates of this remedy may say yes, for has not Dr. Hitzig, of Halle, proved beyond doubt that morphine which has entered into circulation will return to the stomach, be secreted there by the glands, and acted upon by the permanganate as fast as secreted? This is very nice in theory, but in practice, how about the glandular coating of the stomach? Will this not be partially destroyed by the continued contact with the permanganate, and thus secretion likewise be destroyed? We have grave fears of corrosion. As has been mentioned before, deoxidation would quickly take place in acid media; this assumption is without doubt true, for were it not so the permanganate would certainly be absorbed, enter the blood, and cause disturbance there. The latter not being the case, is quite conclusive evidence that oxidation of the lining of the stomach must result, and any poison having entered the circulation is sure to stay there unless counteracted by physiological antidotes; the proposition to give hypodermic or intrarenal injections of the permanganate seems ridiculous, for the blood would soon annihilate it.

We will not attempt to state here, at the present, what changes would occur, but we may easily judge what might happen when we stop to consider the composition of blood,—namely, fibrin, serum, albumin; and we can draw conclusions as to what the probable results would be; and it seems more ridiculous when we remember that 1 part of permanganate of potassium is soluble in not less than 16 parts of water, and that at this state of solution it possesses very corrosive properties, and would quickly destroy any oxidizable substance; and as at the rate of dilution at which the doctor uses it by the stomach—namely, 2 grains to the ounce—it would take quite an amount for injection, how foolish to accept this as rational!

The French Academy of Sciences at one time largely used permanganate of potassium for flushing the stomach, and suffice it to say, that it required quite a number of douches successively to eject the solution in its characteristic color. This would go to show that it

does not require very much to destroy the permanganate, and we are very sceptical as to accepting any statements made in relation to the permanganate as antidote for morphine in face of the damaging evidence of its chemical behavior.

#### THE TREATMENT OF THE HECTIC STATE.

In an article published in the *New York Medical Record* for April 14, 1894, STARK asserts that the treatment carried out by himself with satisfaction is as follows: Speaking of the drugs which can be used for the alleviation of the symptoms, the therapeutic indications have reference to the colliquative sweat, the chill, the nervo-muscular prostration, and the hyperpyrexia. So far as the treatment of the hyperpyrexia is concerned there is nothing new to offer. In regard to the treatment of the colliquative sweat and the prostration, however, he puts himself on record in favor of two drugs which have served him admirably, after having experimented with a variety and having subsequently discarded them. These drugs fulfil the physiological and pathological indication in a way that commends them favorably to all practitioners. They are, for the sweat and prostration, atropine, and for the prostration and circulatory disturbances, strychnine. For several years, both in public and private practice, it has been a matter of routine with the writer to combine the salts of atropine and strychnine in a palatable manner in the treatment of this fever complex, and he has up to date yet to learn of a more effective combination. A serious drawback to the freer employment of these powerful drugs has always been the imminent danger of miscalculating the dosage or in committing a chirographical or a mathematical error in writing the prescription or in having it compounded. One physician of the author's acquaintance has stricken these drugs from his personal pharmacopœia on that account. It would appear that this *quasi* obstacle ought not to militate against their use, as it could readily be overcome, to the interest both of the public and of the profession, with a little precision, heroism, and self-confidence on the part of the practitioner.

The mode of operation of these drugs is of importance. It is known that both are cardiac tonics, under certain conditions, which do not at all antagonize each other, inasmuch as they act differently on different functions. Thus, atropine, according to therapeutists, has a paralyzing action on the inhibitory fibres of the pneumogastric and at the same time stimulates

the cardiac ganglia of the sympathetic ; strychnine increases arterial tension and the force of the apex-beat. Further, atropine, if properly administered, will check the profuse sweat that so surely exhausts and prostrates, and will also allay the irritability of the central nervous system. Strychnine is the remedy *par excellence* as a general tonic for the nerve-centres ; in this respect it is almost a specific. The exhaustion and depression caused by the nerve-centre poisoning find here a remedy which strikes at the very root of the affection, without in any way impairing the cerebral functions. Some writers discourage the employment of strychnine in the acute stage of spinal disease, but the writer's experience does not warrant such a conclusion, as he has yet to note an untoward effect or an unpleasant result. *En passant*, he recalls a very serious case of hectic fever accompanying a pyonephrosis, in which there was a daily collapse for three successive days, due to the hectic phenomenon. Strychnine and atropine were administered to the exclusion of all other drugs, and he believes they were the means of tiding the victim over the critical period until an operation was deemed advisable, by economizing his vitality and strengthening the circulation and innervation. The mode of administering these drugs is as follows: He usually combines both salts of the alkaloids in pill form. Of atropine, the adult dose should be  $\frac{1}{100}$  to  $\frac{1}{80}$  grain ; of strychnine,  $\frac{1}{100}$  to  $\frac{1}{80}$  grain. They should be administered one or two hours before the anticipated chill in one large dose, or else in divided doses t. i. d. He usually gives atropine  $\frac{1}{100}$  and  $\frac{1}{80}$  grain strychnine to adults. So far as the atropine is concerned, its effects are delayed at times for one or two days, or its influence may be extended over a like period. Slight atropinization occurs at times, but tetanization never. On this account it is preferable to study the idiosyncrasy of the patient and his tolerance by administering each drug independently at first. He never employs any preparation except the alkaloids themselves, and even in the case of children this rule applies with double strength, for it is an ordinary observation that they tolerate atropine much better comparatively than adults do.

The administration of these alkaloids in no way interferes with the action of other drugs that may be employed for the reduction of temperature ; on the contrary, they enhance their value by counteracting the depressing effects on the heart of the synthetical antipyretics of recent date. It is scarcely necessary to state that not all cases of hectic fever are to be combated with atropine and strychnine,

singly or conjointly. There are many instances of this fever which entirely abate directly the local source of irritation is removed. The point intended to be emphasized is this, that these drugs are of decided benefit for the amelioration of the symptoms in those cases where the pus nidus cannot be precisely located, or where operative procedures are advisedly delayed or expressly abandoned for conservative reasons. In that type of hectic which consists merely of chill and hyperpyrexia, atropine should be discarded.

The following are some formulæ which cover the points brought out by this paper and which are employed by the author :

When hyperpyrexia is insignificant, but the chill, sweat, and prostration are the prominent features :

R Strychninæ sulph., gr.  $\frac{1}{3}$  ;  
Atropinæ sulph., gr.  $\frac{1}{10}$  ;  
Extr. gentianæ, q. s.  
M. et ft. in pilulas No. xii.  
Sig.—One t. i. d.

When all the symptoms are present :

Sig.—One wafer t. i. d. aut p. r. n.

#### MASSAGE AND THE BLOOD.

J. K. MITCHELL publishes his second communication on this subject in the *American Journal of the Medical Sciences* for April, 1894.

To sum up, first, the certain results: In health, massage increases the number of red corpuscles, and to a less degree and not so constantly their hæmoglobin value.

In all forms and grades of anæmia there is a very constant large increase in the number of red corpuscles after massage ; this is greatest at an interval of about an hour, after which it slowly decreases. This decrease is postponed more and more if the manipulation be daily repeated. An improvement also takes place in the general tone of the circulatory and muscular systems.

There is an occasional but inconstant increase in the hæmoglobin value, and this in-

crease is proportionately less great than that of the cellular elements.

It has been doubted if so powerful and fatiguing a method of treatment as massage is safe or desirable in very high grade anæmias. It is now for the first time made clear that it is of great and certain service and without danger in such cases, no matter how feeble.

It is evident, too, that our present definitions of anæmia are insufficient. An essential part of the description in all of them is that there are defects of number, of color, or of both in the blood; this is not necessarily true. The fault may lie in a lack of activity or of availability in the corpuscles. The state of things in the system may be, to draw an analogy from economic conditions, like the want of circulating money during the times of panic, when gold is hoarded and not made use of, and interference with commerce and manufactures results.

Lastly, neither an anæmic appearance nor a blood-count is alone enough for a certain diagnosis. Other signs must be used as a check on the blood examination for the establishment of the existence of anæmia; for instance, many cases here recorded had full normal or even supranormal corpuscle-count, with a good percentage of hæmoglobin; yet they presented every external sign of poverty of blood: pallor of skin and, more important still, of mucous membranes, cold extremities, anorexia, indigestion, dyspnoea on trifling exertion. In such cases we must suppose either that the total volume of the blood is reduced, or that the usefulness of the corpuscles is in some way impaired, or that both these troubles exist together.

The white corpuscles have not received sufficient attention in this study, although it seems as if in most cases they were increased as well as the red.

#### ELECTRICAL TREATMENT OF OBESITY.

IMBERT DE LA TOUCHE (*Rev. Internat. d'Électrothérapie*, August, 1893) has obtained favorable results from electrical treatment in certain cases of obesity in which the symptom had developed as part of a general disorder of nutrition or neurasthenic state in women. Regulation of the diet, as usually prescribed for the diminution of stoutness, made the patients worse. Five cases are reported. The method employed was by insulation and the statical charge, daily or three times a week. Excellent results followed; in every case the symptoms of debility disappeared, the abnormal stoutness disappearing also. The author writes enthu-

siastically of the efficacy of this mode of treatment.—*British Medical Journal*, May 5, 1894.

#### SPINA BIFIDA—A CURE BY IODINE INJECTIONS.

In the latter part of February of the present year WOODYARD (*Virginia Medical Monthly*, May, 1894) was called to see Willie M., aged two months. He was informed that the child had a tumor in the lumbo-sacral region of the spine, and that the midwife in attendance wanted to poultice the same.

He found that he had a spina bifida to deal with. At this time the tumor was about the size of a goose-egg, sessile, translucent, and fluctuating; all the skin covering the tumor, except a place in the centre about the size of a ten-cent piece, was in good condition. When the child cried, the tumor would bulge out and become tense.

In treating this case, conservative methods were employed for a few weeks, until the patient was in good condition, when Dr. J. R. Boyd was called in consultation. As the tumor was growing rapidly, and from all indications would soon rupture, they decided to use iodine injections, thinking they would give the patient a chance, at least, for its life. Accordingly, they aspirated one drachm of fluid from the tumor, and immediately injected into the tumor one drachm of,—

R Iodini, gr. x;  
Potassii iodidi, gr. xxx;  
Glycerini, C. P., ℥i. M.

Following this injection a slight degree of coma was manifest, which lasted about twenty-four hours. The tumor became slightly inflamed for a day or two; after this there were no effects of the treatment appreciable. At the expiration of one week the same treatment was repeated. No coma was shown; the tumor became inflamed within twenty-four hours; the patient was very restless, and refused to nurse. From this time on the skin became wrinkled and the tumor began to diminish in size, and at the end of the third week it had almost entirely disappeared. Nothing remained but a bursa about the size of a twenty-five-cent piece. The patient is now in good condition.

#### IMPETIGO.

R Ung. sulphur., ℥ii;  
Ung. zinci ox., ad ℥i. M.

This application can be employed freely for impetiginous eruptions, and is particularly of ser-

vice for very extensive cases in which mercurial preparations are contraindicated, owing to the risk of poisoning taking place from absorption.

Or,

R Plumbi acetatis, gr. viii;  
Acid. hydrocyan. dil., ℥ii;  
Sp. rectificati, ℥ss;  
Aq. destil., ad ℥viii. M.

For lichen urticatus: A similar ointment to that just given, containing usually a larger proportion of sulphur, gives great relief, especially if the itching papules be first pricked or scratched with a needle.—*Medical Press and Circular*, April 25, 1894.

#### GUAIACOL IN THE TREATMENT OF ORCHITIS.

R Guaiacol, ℥ss;  
Vaselini, ad ℥i. M.

Smear some of the application over a piece of lint and apply it to the scrotum. The pain of the inflamed testis will be much relieved, the relief lasting several hours. The dressing should be renewed twice or thrice daily.

—*Medical Press and Circular*.

#### A NEW TREATMENT OF PULMONARY TUBERCULOSIS.

Dr. Cohn, of Hamburg, has found ichthyol very useful in the treatment of pulmonary tuberculosis. He administers the drug in the following form:

R Ichthyolis,  
Aq. destill., of each, ℥v. M.

The patient begins to take 4 drops of this solution thrice daily, and then the dose is increased by 1 drop daily until the maximum amount of 40 drops three times a day is reached. The best time of administration is before meals. Generally speaking, patients become readily accustomed to the disagreeable taste of ichthyol, but a mouthful or two of black coffee is very efficacious in removing the taste. The ichthyol is said to be far superior to creosote or cod-liver oil.—*Medical Press and Circular*.

#### A PRESCRIPTION USEFUL IN DENTALGIA.

R Tinct. gelsemini, m℥xv;  
Tinct. ferri perchlor., m℥x;  
Syr. aurantii, ℥ss;  
Aq., ad ℥i. M.

For one dose. To be repeated thrice daily.

—*Medical Press and Circular*.

#### A PRESCRIPTION FOR EXTERNAL HEMORRHOIDS.

R Chrysarobin, gr. xvi;  
Iodoformi, gr. vi;  
Ext. belladonnæ, gr. xii;  
Vaselini, ℥vi. M.

A small quantity to be applied to the swellings several times daily, the parts having been previously washed with a solution of carbolic acid (1 in 5).

—*Medical Press and Circular*.

#### HÆMATOPORPHYRINURIA AFTER TRIONAL.

SCHULTZE (*Deut. Med. Woch.*, February 15, 1894) first refers to the cases of hæmatoporphyrinuria after the use of the closely-allied sulphonal. From time to time unpleasant symptoms have appeared after the administration of trional, such as fatigue on waking, slight digestive troubles, very rarely ataxy or stupor, with marked cyanosis and vomiting. Koppers has warned against its use in cardiac disease. The author records the following case in a woman, aged fifty-four, with melancholia. Other remedies against sleeplessness having been used in vain, trional was given in a single evening dose of  $\frac{1}{2}$  to  $1\frac{1}{2}$  grammes, and continued during four or five weeks, twenty-four to twenty-five grammes having been taken in all. Towards the end of this time the patient became worse without any discoverable cause. She had to be artificially fed, and constipation was marked. The patient was taken out a few days after the drug was stopped, and she died a little later. A few days before her discharge the urine appeared of a dark red (almost black) color, and was proved both chemically and spectroscopically to contain hæmatoporphyrin. It is striking that so small a quantity of trional should have had so deleterious an effect. The loss of appetite and severe constipation are to be attributed to it. All the reported cases of hæmatoporphyrinuria after sulphonal, as also the above one, have occurred in women. Trional must be used continuously with caution, and stopped at once if a red color appears in the urine. That this coloration of the urine may be one of the first symptoms of poisoning by sulphonal has been shown by Schaeffer.—*British Medical Journal*, April 7, 1894.

#### DULCIN.

KOBERT (*Centralblatt f. Inn. Med.*, April 21, 1894) says that pure saccharin is described by many as not being really sweet. Dulcin has a pure sweet taste, and excels saccharin in sweetness some two hundred to two hundred and fifty times. In structure it is an aromatic urea

derivative—paraphenetol carbamide—and is allied to phenacetin. It is soluble in eight hundred parts of water at 15° C., in fifty of hot water, and in twenty-five of ninety-seven per cent. alcohol. Experimentally, dulcin has been shown to be harmless to rabbits, but in dogs, which are more susceptible to its action, the evidence is somewhat conflicting. From his own experiments on cats the author concludes that doses corresponding to such as would be used in man are harmless; with abnormally large doses the cats became ill, and eventually died with cerebral symptoms. In diabetes it must be used in relatively small doses. Ewald has given it in doses up to 1.5 grains in the day. The author concludes that dulcin in reasonable doses is, so far as we know at present, harmless, and is an advance upon the use of saccharin, owing to its sweeter taste. It does not bring about any decomposition of the blood.—*British Medical Journal*, May 26, 1894.

#### MALAKIN.

F. MERKEL (*Munch. Med. Woch.*, April 24, 1894) observes that this drug has been recommended as an antipyretic, antirheumatic, and antineuralgic. It is a salicylic derivative, and contains about fifty per cent. of salicyl aldehyde; thus, four grains correspond to a little more than two grains of salicylic acid. The author has tried malakin in eighteen cases,—fifteen of acute rheumatism, two of enteric fever, and one of neuralgic pains in typhlitis. Its action is very mild, and no unpleasant by-effects are noted; at most, the profuse perspirations generally following its administration might be looked upon as unpleasant; perhaps the quality of the pulse suffered occasionally. The drug has a distinct antipyretic effect, but this is not permanent. As an antirheumatic it can produce a decided improvement in the articular manifestations. In fifteen cases of acute rheumatism a favorable effect was noted in nine, and in two of these other remedies had been used without benefit. The author looks upon malakin as an addition to our resources where other remedies fail. Whether it can be given like the salicylates in larger and more frequent doses remains to be shown.—*British Medical Journal*, May 26, 1894.

#### CARE OF THE MOUTH IN SICK PERSONS.

ROSENBAACH (*Zeit. für Krankenpflege*, April, 1894) says that in many illnesses there is almost sure to be secondary trouble in the mouth if preventive measures be not taken. A warn-

ing sign is dryness and redness of the tongue and mucous membrane of the mouth, with difficulty in swallowing; further signs are an evil odor from the mouth, coated tongue and gums, bleeding of the gums, etc. Just as special care of the mouth is required in patients with carious teeth, smokers and chewers of tobacco, so it is also in the case of unconscious or paralyzed persons; patients with fever or suffering from chronic digestive complaints; those taking medicines, such as mercury or iodides, or who, on account of general weakness, have to take strong alcoholic drink; but perhaps the most important class of those in whom special care of the mouth must be taken are patients with fever. Parasites are always present in the mouth, but it is only when the tissues are weakened that they undergo invasion by these parasites. There is nothing which one can do for sick persons which is unimportant, and by neglect in the care of the mouth convalescence may be retarded.

Rosenbach concludes with the following rules:

1. Patients with good digestive powers, free from fever, and with no loss of consciousness require no more than the ordinary care of the mouth.

2. In children and very old patients the less solid food taken the greater should be the care with the mouth. They should rinse the mouth out several times a day with lukewarm water containing a little common salt, tincture of myrrh, or eau de Cologne added to stimulate secretion. When there is a tendency to bleeding of the gums, or when the teeth are bad, a pinch of powdered boric acid may be twice daily rubbed in between the lips and gums. Patients with false teeth should remove their false teeth when, owing to loss of appetite or chronic gastric disturbance, they cannot take solid food.

3. In patients with partial loss of consciousness the mouth should be examined several times a day for small sores, such as may arise from the pressure of the teeth on the lips, etc. Such sores should be powdered with a little boric acid or chlorate of potassium, and the cracks at the corners of the lips heal quickly if dried with a clean towel and treated with boric acid or vaseline. The mucous membrane may be stimulated by wiping the tongue and mouth and pressing on the tongue with a moist towel every two or three hours; if necessary, the hinder part of the tongue should be cleansed with a wad of cotton-wool fastened to a stem. If the patient sleep with the mouth open, the air in the room must be kept moist; a moist-

ened layer of muslin laid on the mouth may be of some service.

4. Patients with fever should have something to drink—cold water or weak lemonade—at least every hour; one must not wait until the patient asks for drink. Besides preventing dryness, the fluid maintains the activity of the glands and the whole function of the mucous membrane. Many patients are prevented from drinking by a painful, dry, and cracked condition of the lips, and therefore all feverish patients should from the commencement of their illness have their lips rubbed several times a day with vaseline or fat. In protracted cases of fever the mouth may also be swabbed out with oil, fat, or greatly-diluted glycerin.—*British Medical Journal*, May 26, 1894.

*NEEBE'S TREATMENT OF SWEATING  
FEET BY CRUDE HYDROCHLORIC  
ACID.*

When the feet are very tender, especially in hot weather, treatment is preceded by an eight to ten days' application of compound talc powder, which is sprinkled in the stockings. The application of the acid is best made in the evening. The crude hydrochloric acid is poured into a flat vessel of stone or glass or porcelain, sufficiently large to receive the two feet. Since the soles of the feet and the skin between the toes are the seat of the trouble, sufficient hydrochloric acid is poured into the vessel to completely cover the soles. It should not be allowed to come in contact with the skin of the back of the feet. The heel is kept in the acid for five minutes; then the sole of the foot for ten minutes. After this the feet, especially the skin between the toes, are washed in soap and warm water. Soaking in the acid must be at once stopped as soon as pain is excited, and the painful spots must be treated with zinc ointment until healing is complete. The process of soaking may be repeated twice weekly, and continued for from five to eight weeks in obstinate cases.—*Medical Press and Circular*, May 2, 1894.

*HÆMOPTYSIS.*

In the *British Medical Journal*, April 21, 1894, FOXWELL writes of this subject, and thinks the rationale of its treatment is simple. It can be divided into two parts: (1) when the hæmoptysis arises from lung-mischief secondary to cardiac failure, and (2) when it is due to primary lung-disease.

The hemorrhage occurring in cardiac disease

is due to a degeneration of the endothelium with consequent thrombus in a branch of the pulmonary artery, owing to feeble circulation, thus causing an infarct, the hemorrhage itself arising from necrosis of a vessel or vessels in the infarcted area from inflammation in the tissues surrounding it. But the tension of blood is very low, the effused blood quickly clots and lies against the opening, the blood within the vessel looks on this clot as a foreign body, and forms a thrombus upon it which soon occludes the bleeding-point. The indication in cardiac hæmoptysis is, therefore, to prevent a repetition, and to effect this we have to strengthen the heart by horizontal rest and such tonics as strychnine and digitalis; personally, the writer finds subcutaneous injections, or rather intramuscular ones,—for it is high time we did away with the term subcutaneous,—of liq. strychninæ in the doses we are accustomed to give it by the stomach—3 to 5 minims thrice daily—to be the most efficacious of all means for stimulating the weakened musculature of the heart.

Should the initial cardiac hæmoptysis be very severe, we must at first have recourse to the treatment for hæmoptysis due to primary lung-disease; but even then we must be very chary in adopting measures which depress the heart.

In primary disease we should look upon the bleeding-point much as a surgeon would look upon a bleeding vessel in a sloughing ulcer of the leg, which he had to treat without the aid of any surgical skill. The writer believes he would be very ill advised to employ ergot or any other vaso-motor contractor, for the vessel in the neighborhood of the bleeding-point is diseased, its muscle fibres are degenerated, and therefore the drug will act less upon them than upon the fibres of all the other arterioles of the body; the injured arteriole it will not contract, but it will raise the pressure of the blood within it by its effect on all the healthy arterioles; the result will, therefore, be an increase rather than a lessening of the bleeding, unless, indeed, you should so press your ergot that the general contraction resulting produced heart-failure, and in this way lessened the flow of blood at the bleeding-point, though not to so great an extent as would occur elsewhere. This procedure cannot for a moment commend itself; it is a far more dangerous and a far less efficacious method of producing heart-failure (that is, faintness) than nature's own. She does it by bringing the tension of the blood to a minimum, and the blood ceases to gush from the extreme weakness of the propelling force;

there is the rest of sheer exhaustion, and during it, mechanical and chemical (not physiological) forces create a plug for the hole in the relaxed and flaccid vessel. All the arterial system is in a state of half-empty flaccidity, so that the feeble flickerings of the heart have every encouragement to continue, for nature has provided that it shall have the least possible work to do. And so life is kept going with the smallest possible amount of blood-pressure, thus allowing the plug the best possible chance of establishing itself. But in ergot faintness the blood, so long as it moves at all, must move under considerable pressure, and hence plugging will be much less likely to take place. Moreover, the strong contraction of the arterioles gives the worn-out heart far less rest, and it has to re-establish the circulation in the least instead of the most advantageous circumstances.

As to ergot, the author has given it a fair trial. His routine treatment when resident medical officer at the General Hospital was 30 grains of Bonjean's ergotine injected deeply into the muscles of the buttock. No injurious effects followed, local or general, nor was he ever able to definitely associate any cessation in the hæmoptysis with its use. But even were it good to contract the arterioles of the lungs, how do we know that ergot will do this? As stated before, the calibre of the pulmonary vessels is under very different governance from that of the systemic ones, and there is no evidence to show that ergot can contract them.

Venesection is sometimes of value at the outset. If the pulse be strong, the individual full-blooded, or if venous congestion exist, then it is easy to see how a timely venesection may diminish the loss of blood; for half a pint of blood withdrawn quickly will lower tension, etc., as much as a pint removed slowly; that is, the quick withdrawal of blood by venesection may do at once what nature is striving to accomplish more slowly,—namely, produce a faintness of the circulation.

Again, anything which keeps the blood in the systemic circulation, and so produces anæmia of the lungs, is beneficial. We know that the splanchnic area can contain all the blood of the body; any therapeusis, therefore, tending to fill this area must be good; large doses of nitrites, which relax the systemic arterioles, should thus prove of service, as well as the constant supply of small portions of food, so as to keep up a constant demand for blood in the alimentary tract.

To fulfil the same end ligatures may be applied to the thighs and upper arms to prevent

the blood reaching the right heart, a procedure well spoken of by Walshe. Leeches to the anus or a hot foot-bath have proved similarly useful. Till faintness come on, the sitting posture is preferable; in this way the head is less supplied with blood, and so less able to stimulate the heart's action than if the horizontal position were maintained.

Any means which may increase the coagulability of the blood is evidently of value. It is for this reason that the swallowing of gallic acid is recommended, though the method of its action is unknown to the author; nor does he think the evidence in its favor is considerable. That it does reach the blood in these cases is shown by the fact pointed out by Wood, that the blood spat up after its exhibition often has a greenish hue.

In July, 1893, Professor A. E. Wright, of Netley, made a communication to the *British Medical Journal* on "The Value of Calcium Chloride as an Increaser of the Coagulability of the Blood." He showed, also, that in too large doses it delayed greatly the period of coagulation. In cases of chronic bleeding—for example, hæmophilia—doses of 5 grains taken thrice daily were most beneficial, but to produce a sudden and complete effect, such as would be our desideratum in severe hæmoptysis, a large single dose of  $\frac{1}{2}$  drachm would obtain the maximum effect, which, in the professor's own case, reduced the coagulation time of his blood from four to one and three-quarters minutes.

Of all measures for the relief of hæmoptysis, perhaps the induction of vomiting has the strongest clinical value of any; but the rationale of its action is certainly obscure, and, though he has thought much about it, the author is not in a position to offer any elucidation of the problem. It matters little what drug be employed for the purpose, whether it be a local irritant, such as salt and water, or one acting on the centre, such as antimony. Personally, he prefers antimony, as it produces relaxation of the systemic arterioles as well.

Hydragogue purgatives are of extreme value, as they deplete the abdominal organs, and so enable them, in turn, to drain other parts of the body. Among them calomel possesses a double virtue, as mercury is one of the best, if not the best, drugs we possess for lowering arterial tension. Its great antiphlogistic power adds still more to the efficacy of mercury.

The great thirst which often accompanies prolonged bleeding is best assuaged by the sucking of small pieces of lemon, as the exhibition of fluid drinks, except as nutriment, is to

be deprecated, our aim being to keep the quantity of the blood as low as possible and its quality as concentrated.

A cool atmosphere is supposed to be advantageous. There is no doubt that it is so in the case of epistaxis, and the nose is one portion of the respiratory tract; so it is hoped that it will be so to the vessels of the lung parenchyma, though we must remember, first, that, whatever the temperature of the outside air may be, that in the air-sacs is constant; and, secondly, cold air is a stimulant to cardiac action,—an action we wish to depress; hence he believes a warm room to be preferable.

Another important aid with which nature has provided us is the most capable ligature in the elasticity of the lungs. As blood is effused and more blood from the right lung takes its place within the vessel, the effused blood distends those alveoli into which it flows, and the elastic walls of these, in turn, increase the pressure which they had previously exerted, and so press the effused blood with increasing force against the ruptured wall of the vessel. This natural ligature it is evidently our duty to aid by all the means at our disposal, and for this reason he would shun any method of therapeutics which would accentuate the act of inspiration, such as the inhalation of astringent sprays.

The application of an ice bag to the præcordium, inasmuch as it is a powerful cardiac depressant, is valuable, but, in so far as it chills the surface of the body, it is undesirable. As ice in some form or other is usually importuned for by the patient, it is perhaps well at once to resort to this method of its exhibition, and the bag will be most wisely placed upon the præcordium. As to its local application over the bleeding-point, even if we could accurately localize this, its advisability is to be doubted, owing to our want of knowledge of the effect of cold on the pulmonary vaso-motor nerves and of the depth to which the cold of an ice-bag can penetrate. Experimentally, but not clinically, it seems to have been shown that the cutaneous application of ice to the chest has produced local anæmia of the subjacent lung.

He concludes the paper with the exhortation, "Above all things, let the thought of morphine be kept ever in mind." As a chain's strength is that of its weakest link, so is the hæmoptotic force of a circulation that of its strongest pulse. One strong beat may thrust away the plug which many feeble predecessors have allowed to form. A vascular serenity is, therefore, an absolute essential in the treatment of hæmoptysis.

#### SCOPOLAMINE IN OPHTHALMIC PRACTICE.

RAEHLMANN (*Wiener Medizinische Wochenschrift*, No. 20, 1894) thinks that scopolamine resembles in its action hyoscyne, but that it surpasses in valuable qualities all other mydriatics. He refers to his previous investigations with scopolamine, already reported in the THERAPEUTIC GAZETTE. His first observations were made with the hydrochlorate of scopolamine, but now he prefers the hydrobromate. A one-per-cent. solution of it acts more energetically than atropine in inflammation of the anterior portion of the eye,—for example, iritis,—and also causes the subsidence of pain more rapidly. It may be used in much more active dose, because it seems nearly free from poisonous symptoms, and even when unpleasant accidents occur they are not dangerous. In his clinic, where one-tenth- and one-fifth-per-cent. solutions are used, occasionally one-half- and one-per-cent. solutions are employed and continued for some time. Sometimes they are without effect on the general condition; at other times there is dryness of the throat and a staggering gait resembling drunkenness. He refers at length to the difference in the physiological action of scopolamine and atropine upon the general condition, showing that the heart's action of the two is an exactly opposite one; so, also, are their effects upon the brain. He concludes by assuming that all experiences thus far reported indicate that scopolamine is a much more desirable mydriatic than atropine.

#### A NEW PROCESS OF SIMPLE MUSCULAR ADVANCEMENT.

MOTAIS (*La Médecine Moderne*, May 9, 1894) thinks that simple muscular advancement is indicated (1) in paretic strabismus of five to fifteen degrees, which is not being affected by general treatment; (2) in cases of strabismus in young children; (3) in cases of persisting deviation, not exceeding twelve degrees, which resists optical and orthothalamic treatment; (4) in compound strabismus, when the superior deviation does not disappear after correction of the internal strabismus; (5) in muscular insufficiency, except in myopic insufficiency. The present process of simple muscular advancement is defective, because the antagonistic muscle causes the sutures to loosen. Motais proposes a new process, in which he uses two threads, each supplied with a needle at the two ends. The first is basted two millimetres from the line of insertion all along the tendon. One

of the needles of the second thread is basted in the same way two millimetres behind the first; the tendon is cut close to its insertion. The two superior needles are then passed under the conjunctiva, which they cross in a line with the vertical meridian. The same thing is repeated with the inferior needles. The tendon is drawn to the desired place and the threads tied on the bridges of the conjunctiva which they separate. The threads are left in place for eight days and the eye covered with a bandage.

#### SUBCONJUNCTIVAL INJECTIONS OF SUBLIMATE.

GAGARIN (diss. St. Petersburg, 1893; abstract *Archives of Ophthalmology*, January to April, 1894) used repeated injections of sublimate in many cases of iritis gummosa, plastic iritis with various complications, irido-choroiditis after recurrent fever, different forms of irido-cyclitis and irido-choroiditis, parenchymatous keratitis, corneal ulcer with hypopyon, different injuries with their consequences, episcleritis, absolute glaucoma, disseminate chorio-retinitis, optic neuritis, and trachomatous pannus. He obtained good and rapid results in hypopyon keratitis, irido-cyclitis, and irido-choroiditis, the hypopyon disappearing. The continuation of the injections did not cause much further improvement. In the various forms of iritis the result was also good. In parenchymatous keratitis and episcleritis no improvement was obtained. In one of two cases of pannus there was a considerable clearing up of the cornea in a short time. The proper dose is a quantity occupying two or three divisions of a Pravaz syringe of 1 to 1000 solution. Stronger solutions cause local symptoms of irritation. It was rarely necessary to make more than three or four injections, and often one or two were sufficient. The effect on pain was very marked when three per cent. of cocaine nitrate was added to the sublimate solution. The necessary general treatment and the local use of mydriatics should not be neglected.

PENNOW (abstract *ibid.*), in one hundred and forty cases of different eye-diseases, used subconjunctival injections of sublimate (1 to 3000 and 1 to 2000, one to four divisions of a Pravaz syringe every three to six days). The pain produced was not marked. The constant swelling of the conjunctiva lasted two to seven days. The effect was particularly good in beginning purulent iritis and irido-cyclitis after cataract extraction; in traumatic cyclitis with

beginning sympathetic ophthalmia the injections were made in both eyes; both were cured, and enucleation was not necessary; in chorio-ditis, chorio-retinitis, and neuro-retinitis, particularly when syphilis was the cause, and in one obstinate case of diffuse opacity of the vitreous. In hypopyon keratitis, parenchymatous keratitis, and in a case of embolism of the central artery of the retina considerable improvement was obtained. In atrophy of the optic nerve (three cases) the effect was doubtful. In most of the cases the indicated general treatment was not neglected.

LAGRANGE (*Annales de la Policlinique de Bordeaux*, No. 19, March, 1894) has especially employed subconjunctival injections of sublimate in the treatment of interstitial keratitis. They are used in conjunction with cocaine and therefore are painless, and in almost every case have caused a much more rapid cure than with general medication alone. He, however, uses this general medication in conjunction with the subconjunctival injections. In one case of specific neuro-retinitis an excellent result was obtained.

M. GROSSMAN (*Annales d'Oculistique*, April, 1894), in the Medical Society of the Hospitals of Buda-Pesth, reports his experience with this method of treatment, especially in two cases of chronic retrobulbar neuritis. The first of these patients received during intervals of six and eight days fourteen injections, and the second eighteen injections from  $\frac{1}{10}$  to  $\frac{1}{5}$  milligramme of sublimate, and the sight sensibly improved. In one case of chronic glaucoma the sight is said to have been improved when iridectomy failed. Another surgeon, who has performed a great number of injections, attributes special value to them in affections of the vitreous body and in choroiditis.

#### THE CONTINUOUS CURRENT IN ACUTE IRIDO-CHOROIDITIS.

DR. PANSIER (*Annales d'Oculistique*, April, 1894) writes concerning the use of continuous currents in chronic iritis, and refers to the fact that it is not a new thing, as Carnus, twenty years ago, reported several observations on the disappearance of irido-capsular attachments under the influence of voltaic electricity. Pansier has used the continuous currents in similar cases without obtaining a satisfactory result; in fact, he could not accomplish the complete resolution of the exudations nor the entire disappearance of the synechiæ, although there was manifestly a sedative influence.

In view of the successful action of the con-

tinuous currents in the subacute period, he concluded to try them in acute inflammations, and he was soon able to experiment upon a patient suffering from exceedingly painful and obstinate irido-choroiditis. He details a number of observations of this character, and then proceeds to say that the sedative effect is lasting; the pain does not always disappear after the first or second treatment, but never continues after the sixth.

In all of these experiments he used a battery of eighteen small elements of zinc and carbon. In this voltaic pile the exciting liquid is alum, which has the advantage of producing a weak and constant current which does not exceed five milliampères. The electrodes consist of two sponges dipped in a solution of chloride of sodium. The negative pole is applied to the eyelid and the positive pole towards the mastoid process in the region of the superior cervical ganglion; each treatment lasts from five to twenty minutes. He attributes the good effect to an influence upon the nutrition of the eye exercised through the vaso-motor system, producing a calming and antispasmodic effect. He is by no means willing to grant too much to electricity, but looks upon it as an adjuvant to other treatment.

---

*THE INJECTIONS OF A SOLUTION OF THE OIL OF BINIODIDE OF MERCURY IN THE TREATMENT OF THE OCULAR MANIFESTATIONS OF SYPHILIS.*

PARISOTTI (*Annales d'Oculistique*, April, 1894), after referring to the work of Vibert, observes that the biniodide of mercury was used in ocular therapeutics, in association with the iodide of potassium, by Dr. Martin, in the form of hypodermic injections, and that this treatment was recommended by Fisher in 1889. The idea of using an oily substance belongs to M. Panas.

The following is the formula and the manner of its preparation:

Pure olive oil, 1000 parts;  
Ninety-five-per-cent. alcohol, 300 parts.

The mixture is left for four or five days, being shaken from time to time. The alcohol floats on the surface and is then separated. This relieves the oil of the oleic acid. The oil is then placed in a porcelain capsule for ten minutes and heated to a temperature of 110° to 113° C. This sterilizes the oil and removes the traces of

the alcohol. When the temperature of the oil has again fallen to 60° C., four parts of the biniodide of mercury are added, and the mixture is shaken until the mercury is completely dissolved. The solution is strained through sterilized cotton and preserved in a sterilized bottle. Each gramme of oil contains four milligrammes of the biniodide of mercury.

Recent discussion in the treatment of the ocular symptoms of syphilis in the French Society of Ophthalmology showed the danger of the use of insoluble salts of mercury in the treatment of this disease. Parisotti has been careful to experiment thoroughly before advocating the preparation which he describes. He records a number of cases thus treated, including interstitial keratitis, iritis, and paralysis of the external ocular muscles, and believes that these cases prove that the injections are very valuable because their action is rapid. Nevertheless, he has never witnessed in any case so instantaneous an effect as he has observed with calomel. With calomel he has seen synechiæ break down, iritis and its pain disappear, and pericorneal injection subside in a few hours. Biniodide of mercury requires a longer time, but still it possesses many advantages over calomel, although the dangers of the latter drug have been exaggerated. In summing up, he believes that the biniodide of mercury is very useful, but that when the danger is great, and when the conditions are such that rapid action is required, hypodermic injections of calomel should be employed. It is interesting to observe that his patients at the same time took large doses of iodide of potassium.

---

*TREATMENT OF GRANULAR OPHTHALMIA.*

LAGRANGE (*Annales de la Policlinique de Bordeaux*, No. 19, March, 1894) contends that acute granulations should not be treated surgically, but in chronic cases, especially when the granulations are large, surgical treatment produces better results than other methods. He believes that the scraping of the granulations should be followed by brushing with a sublimate solution (1 to 500), and he employs a special instrument for this purpose,—a species of curette, curved on its back and containing on its convex surface small teeth, which scrape away the granulations, but do not penetrate too deeply. He is satisfied with surgical treatment, although he is unwilling to assert that he has cured every patient, and is content with the belief that they have been much benefited.

*THE EXTERNAL USE OF QUININE IN BLENNORRHOIC OPHTHALMIA.*

DR. GEORGE REICH-HOLLENDER (*Archives of Ophthalmology*, January to April, 1894) treated cases of gonorrhœal ophthalmia and ophthalmia neonatorum in the usual manner,—namely, with iced compresses, nitrate of silver, and frequent cleansing with a mild antiseptic solution; and after failing to get a good result with a one-fourth-per-cent. solution of permanganate of potassium, concluded to try quinine alone as an eye-wash every hour, and did it with the happiest results. It should be noted, however, that he continued to use nitrate of silver and iced compresses. He believes that quinine, either completely or partially dissolved, is a specific in the ravages of the gonococcus, either in gonorrhœal ophthalmia or in ophthalmia neonatorum. His formula is as follows:

Sulphate of quinine, 2.  
Dilute muriatic acid, .75  
Distilled water, 180.

Sig.—Shake well and use as an eye-wash every hour.

[Quinine lotion in the treatment of purulent ophthalmia is an old remedy. It has also been much employed, on Tweedy's recommendation, in membranous and diphtheritic ophthalmias.—ED.]

*MORPHINE HYPODERMICALLY AS A MEANS TO PREVENT PROLAPSE OF THE IRIS IN SIMPLE EXTRACTION.*

DR. EUGENE SMITH (*Archives of Ophthalmology*, January to April, 1894) recommends, after the toilet of the eye, subsequent to cataract extraction, a drop of a 1-grain solution of salicylate of eserine into the conjunctival cul-de-sac and a hypodermic injection of  $\frac{1}{4}$  grain of the sulphate of morphine. He then waits a few minutes and allows the patient to go to bed, where he remains from twenty-four hours to two days. Eight hours after the first hypodermic injection of morphine he gives another, and the following morning a third. This generally keeps the pupil contracted from thirty-six to forty-eight or more hours. The morphine injection relieves the discomfort immediately following the operation, produces tranquillity, checks a cough, if present, and does away with involuntary traction of the recti or orbicularis muscles. Given hypodermically, according to Dr. Smith, morphine does not produce vomiting. He does not pretend to explain the action of morphine, except that he believes it produces contraction of the pupil

and that he has demonstrated to his own satisfaction its usefulness under the conditions recommended.

*CORRECTION OF STRABISMUS.*

LAGRANGE (*Annales de la Polyclinique de Bordeaux*, No. 19, March, 1894) believes that children with convergent strabismus should not undergo operation if they are under the sixth year of age. After this, and when the strabismus is marked,—twenty or twenty-five degrees or more,—he has recourse to a surgical operation without waiting for stereoscopic exercises, which do not appear to be entitled to a definite place in practice, except as complementary to surgical treatment. He believes that double tenotomies are suitable for cases of alternating strabismus almost equally distributed to both eyes and both suffering from some defect of refraction to an equal degree. When only one eye is strabismic, a correction should be applied to it alone, cutting a shorter tendon, and if this is not adequate, by adding to it capsular or muscular advancement. Operations performed with the aid of cocaine alone are more satisfactory. Those done under the influence of anæsthesia cause a disturbing factor, because the eyes of the anæsthetized patient are directed upward and outward. He believes it is very important to attempt to get binocular vision by means of suitable stereoscopic exercises. It is most important after an operation to watch the patient for a long time, and always as long as the sutures are in place, in order to loosen or tighten them, according to circumstances.

*A SUGGESTION OF AN OPERATION TO CORRECT ASTIGMATISM.*

DR. W. H. BATES (*Archives of Ophthalmology*, January to April, 1894), after referring to the well-known fact that contraction of corneal scars produces permanent corneal astigmatism, details several cases of this character, from which his suggestion to operate for astigmatism has been derived. The following propositions are submitted:

1. A corneal incision lengthens the radius of curvature of that corneal meridian which is at right angles to the line of the incision, and does not flatten any other meridian. The astigmatism produced is a regular astigmatism, and is corrected by a convex cylinder at an axis parallel to the line of the incision.
2. The immediate result is greater than the ultimate result.
3. The astigmatism produced is permanent

after a length of time,—at least a month after the cornea has healed. There may be at first 3.D. of astigmatism produced. At the end of a month there may be 2.D. At the end of three months the astigmatism may still be 2.D., and this amount of astigmatism will be permanent.

4. The amount of astigmatism produced is greater the nearer the incision is to the centre of the cornea; as much as 9.D. can be produced.

5. Mixed astigmatism occurs: (a) temporarily; (b) with incarceration of the iris.

*The Operation suggested.*—Incisions of the cornea are made at right angles to the most convex meridian. The amount of correction can be regulated by the number, depth, and location of the incisions.

The operation promises a permanent effect. The risk to the eye is not great. It is not as dangerous an operation as the operation for iridectomy, which is usually performed without accident. Incarceration of the iris must be avoided to prevent the development of myopia.

#### IMMEDIATE CAPSULOTOMY FOLLOWING THE REMOVAL OF CATARACT.

DR. L. WEBSTER FOX (*Journal of the American Medical Association*, June 2, 1894) writes as follows concerning his method of capsulotomy:

After the delivery of the lens (cataract) and all cortical matter is washed out of the anterior chamber, he proceeds with the rupturing of the posterior capsule. The instrument used is a gold-enamelled hook, made as delicately as is consistent with keeping its shape. It is of malleable steel, so that it may be bent to any angle which he finds convenient, especially when the eye of the patient lies deep in the orbit. The hook is passed into the anterior chamber, and behind the lower pupillary margin of the iris, on its flat side. It is then rotated backward, hooked into the capsule, drawn gently upward to the mouth of the incision, rotated on its flat side again, and then taken out of the chamber. By this means the capsule is torn and the vitreous presses forward between the rent. Very little or no vitreous shows at the mouth of the wound; if it does, he snips it off.

When the operation is performed after the simple method (without iridectomy), the same manipulation is carried on, with but one exception, and that is, the line of incision is not so long. The ophthalmostat is removed and the eyeball again irrigated with the hydrostatic eye-

douche, followed by dropping one drop of sterilized atropine solution into the eye; the lids closed and thickly anointed with vaseline, which has been sterilized by boiling; over this specially-devised eye-pads, which have also been sterilized by heat, held in place by adhesive strips, which keep the bandages securely fixed, permitting the patient to change his position in bed as often as is desirable. In twenty-four hours the dressings are removed and both eyes bathed with warm water and irrigated with the sulpho-carbolate solution, another drop of atropine applied, and similar eye-pads adjusted with as much care as at the primal operation, and so continued from day to day until the eye is out of danger.

#### TREATMENT OF EPITHELIOMA.

DARIER (*La Médecine Moderne*, May 12, 1894) has obtained excellent results with the following dressing: First dry the ulcerated surface, then cauterize with any cautery,—thermo-cautery, galvanic-cautery, or, still better, chromic acid,—and finally use a solution of 1 to 100 of methyl-blue, either in repeated paintings or in interstitial injections. Recovery often follows at the end of one or two months. Abadie, from personal observation, believes that the chromic acid is unnecessary, and that the methyl-blue alone is effective. He points out that the improvement is often exceedingly slow, and months may pass without appreciable change, and this probably accounts for the fact that it has been abandoned by many practitioners.

#### ANTIPYONINE AND ITS EMPLOYMENT IN OCULAR THERAPEUTICS.

ROLLAND (*La Médecine Moderne*, May 12, 1894) has used antipyonine for three years exclusively in the treatment of keratitis and conjunctivitis. His experience, which has resulted from one thousand patients, has caused him to believe that no other medicament could have resulted in so many cures. The drug should only be applied by physicians, and insufflated in small, large, and excessive quantities, according to the condition. In small quantities it is suitable for phlyctenular keratitis, mild degrees of pannus, fascicular keratitis, hyperæmia of the conjunctiva, and phlyctenular conjunctivitis. In large quantities it is effective in the treatment of abscess, ulcers of the cornea, fleshy pannus, catarrhal, follicular, and granular conjunctivitis. It is indicated in

very large quantities in purulent conjunctivitis, panophthalmitis, after enucleations, and in large traumatism.

*PURULENT OPHTHALMIA: TREATMENT, ETIOLOGY, AND PROPHYLAXIS.*

ABADIE (*La Médecine Moderne*, May 12, 1894) points out that, although in laboratory experiments weak solutions of sublimate, carbolic acid, iodoform, naphthol, resorcin, and permanganate of potassium destroy the virulence of the gonococci, they do not accomplish this result when this microbe is found in the living tissue of the conjunctiva. All substances are then powerless to avert the evil. They have not a really curative action; they can only arrest to a limited extent the fatally progressive evolution of purulent ophthalmia. Nitrate of silver, on the contrary, has a truly specific and consequently truly curative effect on the gonococci, even when they develop in their favorite element, the human conjunctiva. Sometimes, if it is used too soon and in the earlier stages of the disease, it causes a very unfortunate change in the character of the inflammation, which assumes a diphtheritic aspect. As a general thing, the strength of the solution should not exceed three per cent., but the application should be thorough, so that the entire surface of the conjunctiva is reached, and the superficial slough which results should be entirely removed before a second application is made. He thinks that boracic acid, sublimate, and permanganate of potassium (1 to 1000) are about equal in their effects, but prefers during the intervals of the active applications of nitrate of silver a solution of the same drug (1 to 1000) in continuous sprayings, as recently recommended by Burchardt.

*MAGNET OPERATIONS FOR THE EXTRACTION OF PARTICLES OF IRON FROM THE INTERIOR OF THE EYE.*

HILDEBRAND (*Archives of Ophthalmology*, January to April, 1894) reports sixty-six magnet operations performed by Dr. Mayweg during eleven years, with fifty-three successes. When an iron foreign body in the interior of the eye is recognized with certainty, its extraction is indicated, even if it is firmly attached to the background, and it is advisable to operate as soon as the presence of the foreign body can be ascertained. If it is impossible to locate the foreign body, it is safer to wait until the media have cleared than to stir the vitreous

extensively. Mayweg believes that local anaesthesia is fully as good as the general anaesthesia recommended by Hirschberg. Hirschberg advises immediate explorative probing with the pointed electrode through the original wound; Mayweg introduces the magnet, apart from the cases in which severe inflammation is present, only when the foreign body can be diagnosed with certainty and its seat determined.

*MINOR PLASTIC OPERATIONS ABOUT THE EYE.*

H. GIFFORD (*Archives of Ophthalmology*, January to April, 1894) has modified the ordinary operation for canthoplasty in cases of coma in which the palpebral fissure is very much reduced in length, while the conjunctiva is so atrophic that after lengthening the fissure one cannot easily get enough membrane to prevent the cut from growing up again. His modification consists in covering the cut surfaces made by lengthening the fissure with two small Thiersch flaps, the surfaces being first widened slightly by turning out the skin above and below with stitches, the needle being first passed through the skin at the edge of the cut, then over a small roll of wet cotton, and through the skin again beyond the roll. He has done six operations in this way without failure.

In cases where entropion and trichiasis co-exist, with partial ankyloblepharon, he commonly first lengthens the palpebral fissure, then splits the edge of the lid, as in Thiersch's operation, extending the incision at the outer extremity until it passes into the raw surface made by the cut to lengthen the fissure. Then, after turning back the outer flap with stitches passed over a cotton splint, as before described, the gap in the edge of the lid is filled with a Thiersch's flap, or a strip of lip membrane cut long enough to extend clear to the extremity of the newly-lengthened palpebral fissure.

Gifford has made use of Thiersch's flaps in repairing losses of the conjunctiva, and his experience, on the whole, is satisfactory, although not in every instance. In cicatricial entropion he combines the Wolfe and Thiersch flaps,—that is, he first places upon the surface a Wolfe flap, and after eight or nine days, when the breaking down of the epithelium of the flap indicates the usual necrosis of the upper layers, he scrapes and cuts these away until healthy bleeding tissue is reached, and then applies a large Thiersch flap.

### THE EYE-TREATMENT OF CHOREA.

DR. A. L. RANNEY (*Medical Record*, May 5, 1894) contributes an article upon this subject, and respecting the relationship of chorea to the anomalies of the visual apparatus he draws the following conclusions:

1. Choreic subjects belong to one of two classes: (a) those who tend to get well under almost any treatment, or even without treatment, and (b) those who fail to get relief from any medicinal aid. The latter tend to run a chronic course, usually one of unfavorable progression.

2. The chronic form of chorea is one of the most serious and hopeless of nervous maladies when treated by drugs alone. It is not infrequently associated with epilepsy or with mental impairment later in life. Chronic sick-headache may often be developed, and sometimes asthenopic symptoms are quite prominent.

3. Both forms of chorea are based, as a rule, upon a well-marked neuropathic or tubercular predisposition.

4. The pathology of chorea is not known. No one has ever proved that it was a "constitutional disease," in the sense that an organic lesion was essential to its development.

5. The percentage of hypermetropia (usually latent) in choreic subjects is extremely large (apparently about seventy per cent.). He makes it a rule, with few exceptions, to correct the total error of refraction in choreic subjects fully by glasses. Often atropine has to be instilled into the eyes at frequent intervals, for a time, in order to arrest ciliary spasm, and enable the patient to accept a full refractive correction without marked discomfort.

6. The glasses ordered for choreic patients should be most carefully fitted to the face and accurately centred to the pupils.

7. An investigation for latent heterophoria should always be made in choreic subjects with the greatest of care and patience.

8. The relief of marked heterophoria should be finally attained only by graduated tenotomies upon the muscles exhibiting abnormal tension, or by an advancement of the tendons of the muscles exhibiting defective power.

9. Prismatic glasses are not curative. They should not, as a rule, be prescribed for constant use.

10. Choreic subjects are usually rapidly cured by eye-treatment alone. So large has been the percentage of recoveries to the total number seen by him during the past ten years, that he has come to regard the prognosis of chronic chorea as extremely favorable.

11. The eye-problems encountered in choreic subjects are not, as a rule, as complicated and difficult to solve as those of epileptics; nor, in his experience, is the duration of eye-treatment apt to extend over as long a period before very decided benefit is observed.

12. He believes that the spasmodic movements which accompany and indicate organic lesions of the brain—as, for example, those of a lepto-meningitis—exist in but a small proportion of choreic subjects, and are usually associated with other evidences of disease.

That organic lesions of the brain and spinal cord may produce choreic movements of an extreme type cannot be denied; but it is wise, in his experience, to be slow in giving an unfavorable prognosis in any case until all possible reflex causes of chorea have been thoroughly investigated and corrected.

13. The removal of young choreic subjects from school, or of adult choreic patients from business, is a step commonly taken by most physicians while treating chorea by drugs.

It must be apparent to all thinking minds that the rest thus given to the eyes and nerve-centres is a factor in the recovery of acute cases of chorea that is as important clinically as the drugs employed.

### THE ABUSE OF COLLYRIA.

DE WECKER (*La Médecine Moderne*, May 9, 1894), after referring to the necessity of having sterile collyria, is of the opinion that it is unnecessary after every case of extraction to instil atropine on the second or third day and to continue these instillations until recovery is complete, believing that the most perfect cures are observed when, after an extraction properly performed, there is no instillation of collyria.

The use of impure collyria in the treatment of ulcers of the cornea is productive of serious results, and he thinks that ulcers should be treated (1) by careful disinfection of the eyelids and particularly of the palpebral edges; (2) by curetting the ulcers and spraying them, so as to remove all infected parts; (3) by injections of several drops of a solution of sublimate (1 to 2000) under the conjunctiva in the region of the diseased part; and (4) by the rigorous application of a compressing bandage without the use of collyria.

In the discussion which followed, Armaignac agreed with De Wecker on the abuse of collyria, and especially on the manner of using them when given to poor patients who had no means of keeping them clean. Dufour believes that De Wecker goes too far in attempting to

banish collyria, especially atropine. Kalt believed that pilocarpine and eserine should not be used in ulcers of the cornea, but where there is iritis atropine should be used. He thinks that the septic condition of the collyria is unimportant, for these are not, in general, more septic than the liquids of the cul-de-sac. The conclusions of Kalt in regard to the uselessness of attempting to obtain aseptic collyria were vigorously disputed by Darier and Chibret. In the discussion the abuse of cocaine and its deleterious effect on the cornea received prominent attention.

#### SOZOIODOL IN DISEASES OF THE EAR AND THE UPPER AIR-PASSAGES.

TEICHMANN (*Therapeutische Monatshefte*, April, 1894) has used in ear-, nose-, and throat-affections various preparations of the salts of sozoiodol,—namely, the sodium, potassium, zinc, and mercury salts,—and speaks of their use with satisfaction. In polyp formation of the tympanic cavity, without caries, sozoiodol of potassium appears to prevent relapses, but in carious processes it does not appear to have a better effect than other medicaments. He has used it still more frequently in nasal difficulties. In eczema of the nasal entrances a one- to two-per-cent. salve of sozoiodol of mercury, with lanolin as the basis, has produced a very good effect. The various forms of rhinitis suggest a large field for the use of sozoiodol preparations, as they do for other medicated powders. For the most part he has used the sozoiodol preparations, especially the potassium salt, in the after-treatment of operations on the nose and throat, and in his practice it has replaced iodoform.

#### THE TREATMENT OF TRAUMATIC CATARACT.

HALTENHOFF (*La Médecine Moderne*, May 9, 1894) has communicated to the French Society of Ophthalmology an article upon this subject, and after referring to Desmarres's rule that traumatic lenticular cataract should, as a rule, not be operated upon, especially when it is evident that absorption little by little diminishes the volume, refers to those cases in which operation becomes necessary in order to hasten recovery. He believes that repeated paracentesis is only a half measure, and that for young patients the standard linear extraction is to be preferred with a wound of from five to seven millimetres. After the thirty-fifth year, simple extraction or the combined section may be

performed. Sometimes it is necessary to use a scoop in delivering the lens; recourse may also be had to aspiration.

If the absorption of the cataract is about to be arrested in consequence of premature occlusion of the capsular wound, there are several methods at our disposal,—namely, repeated paracentesis, daily massage, and if the capsular wound is definitely closed, extraction in an adult, and discission, aspiration, or linear extraction in a youth. In simple or incomplete cataracts, or with partial opacities, we must be guided by the same principles as in the operative treatment of zonular cataract,—that is to say, either iridectomy or sphincterectomy may be performed.

If the traumatic cataract is complicated with glaucomatous symptoms, myotics may be used, together with a paracentesis or sclerotomy. Some recommend linear extraction at once; others are satisfied with iridectomy.

If the cataract is complicated with an infected wound, it may be possible to preserve the eye by immediate antiseptic treatment in children, but usually in laborers, where time is of great moment, enucleation is in order. If the wound has a good chance of healing, it should be sterilized, prolapse of the iris cut off, and, if necessary, the wound sutured or covered with a conjunctival graft. If there is tardy infection of the wound, and local antiseptics, mercurial medication, and subconjunctival injections of sublimate fail, enucleation becomes necessary. Iritis and irido-cyclitis complicating traumatic cataract are treated in the usual way. Foreign bodies in the lens must be dealt with according to their composition and position. If they are of iron or steel, the electro-magnet is occasionally of use; in other instances the whole lens must be extracted within its capsule.

#### THE COMPARATIVE SAFETY OF SUPRAPUBLIC LITHOTOMY, OF LATERAL LITHOTOMY, AND OF LITHOLAPAXY IN YOUNG MALES.

BARLING (*British Medical Journal*, No. 1740, 1894), partly in answer to a paper by Keegan criticising the statistics of English surgeons, advances figures tending to show that litholapaxy is the safest operation for stone. It will be remembered that Keegan reported six hundred and sixty-three cases of litholapaxy performed by eight surgeons in various parts of India, with a mortality of less than three per cent. On the basis of this he holds that it is

incumbent on those who practise suprapubic operation as a routine method in children to show that it is a procedure not more dangerous than lateral lithotomy or litholapaxy.

English statistics are less favorable than those from India, partly because the Indian surgeons have greater experience in this particular class of cases, partly because the natives of India stand operation better than Englishmen.

Barling collected the statistics of twelve English hospitals. Seventy-two cases under twenty years of age were subject to suprapubic lithotomy; 17.4 per cent. of these died. A larger percentage of the cases under ten perished. Fifty-nine cases were treated by lateral lithotomy; two of these died, both under ten years. Fifty-nine cases were subject to litholapaxy; but one of these died. It is worthy of note, however, that litholapaxy could not be completed in two cases, suprapubic lithotomy being required; both these cases perished.

This statistical study shows that the suprapubic operation is by all odds the most dangerous; four of these cases perished from shock, two from infiltration around the bladder, three from various conditions of the kidney, two from peritonitis, and one each from pyæmia, septicæmia, bronchitis, and pneumonia.

The statistics of a single hospital give results pointing in the same direction, but still more conclusive. From 1870 to 1887 seventy cases were treated by lateral operation, with but two deaths. From 1888 to 1893 twenty-two cases were operated on,—fifteen by the lateral and seven by the high operation. All of the lateral operations recovered, while four of the high operations ended fatally.

#### *SURGERY OF THE GALL-BLADDER AND BILE-DUCTS.*

MAYO ROBSON (*British Medical Journal*, April 28, 1894) contributes brief notes of seventy-eight consecutive cases embodying his operative experience of the surgery of the gall-bladder and bile-ducts. Among the prominent symptoms of cholelithiasis he places spasm and biliary colic without jaundice, the attacks being repeated at longer or shorter intervals, coming on without apparent cause, usually starting in the epigastrium or under the right ribs, and radiating to the right scapular region or to the shoulder, and often ending in vomiting, which usually gives relief. Collapse due to the intensity of the pain, which may cause death without any other complication. Spasms, followed by evanescent icterus. Pain, followed by persistent jaundice and enlargement of the

liver, which may give rise to the suspicion of malignant disease, but which may usually be diagnosed from cancer by the presence of attacks of pain, accompanied by a feeling of chilliness or a rigor, and followed by increased temperature and then by profuse perspiration, the whole attack resembling one of ague. Distention of the gall-bladder without jaundice, ordinarily due to impaction of gall-stones in the cystic duct. If accompanied by persistent jaundice, distention of the gall-bladder raises a suspicion of malignant disease, either of the liver or bile-ducts or of the head of the pancreas. Ileus due to atony of the bowel, apparently dependent on the pain producing a profound impression on the nerves of the abdomen, leading to enormous distention and to the symptoms and appearance of acute intestinal obstruction. Acute intestinal obstruction dependent on (a) paralysis of gut due to local peritonitis in the neighborhood of the gall-bladder; (b) volvulus of small intestine; (c) impaction of large gall-stone in some part of the intestine after ulcerating its way from the bile-channels into the bowel. Hemorrhages, the result of long-continued jaundice, either dependent on gall-stones alone or on cholelithiasis associated with malignant disease. Persistent vomiting, with such serious digestive disturbances as to threaten death from exhaustion. Localized peritonitis producing adhesions, which may then become a source of trouble even after the gall-stones have all been got rid of.

The writer believes that nearly every attack of biliary colic is accompanied by adhesive peritonitis, as in his experience in all cases where there have been characteristic seizures adhesions are found. Among the sequelæ of cholelithiasis are dilatations of stomach dependent on adhesions around the pylorus; ulceration of the bile-passages, establishing a fistula between them and the intestine; localized peritoneal abscess; abscess in the abdominal walls; fistula at the umbilicus or elsewhere on the surface of the abdomen; empyema of the gall-bladder; suppurative cholangitis; septicæmia or pyæmia; gangrene of the gall-bladder; perforative peritonitis due to ulceration or to rupture of the gall-bladder or ducts; extravasation of bile into the general peritoneal cavity; pyelitis of the right side; cancer of the gall-bladder or of the ducts; subphrenic abscess; emphysema on the right side; pneumonia of the lower lobe on the right side; chronic invalidism and inability to perform any of the ordinary business or social duties.

Where medical means have failed, surgery holds out very good hope of success in nearly

every complication of cholelithiasis, if the patient be not too much exhausted to permit of any major operation. Cases complicated with malignant disease, however, are decidedly unfavorable ones for operation, because the subjects of cancer are not only, as a rule, cachectic and worn down by disease before the surgeon is called in, and therefore unfitted to bear the shock of any operation, but because such patients are particularly prone to hemorrhage at the time of operation or subsequently; this may be uncontrollable.

In order to avert danger from hemorrhage in jaundiced patients, chloride of calcium should be administered for a few days before operation to make the blood more plastic and to lessen the tendency to bleeding both at the time of operation and subsequently. After operation the drug may be continued for some time either by the mouth or by nutrient enemata with advantage. In jaundiced cases all bleeding points should be ligatured, rather than intrusted to pressure forceps for hæmostasis.

In all cases of malignant disease with jaundice on which the reporter operated the gall-bladder formed a perceptible tumor; whereas, when the jaundice was dependent on gall-stones, there was no marked tumor present. Another diagnostic point worth noting is that in cholelithiasis there is usually tenderness on pressure over some point between the eighth or ninth costal cartilage and the umbilicus. In three cases the pain in the so-called "spasms" was referred to the left side, thence radiating to the left scapular region, and in such cases he found the pylorus adherent to the gall-bladder or cystic duct. So-called diagnostic operations of sounding for gall-stones and aspiration of a distended gall-bladder he believes futile and dangerous and much better replaced by a small exploratory incision, when treatment can at the same time be carried out if required.

After medical treatment has been fairly tried and failed, surgical measures should be resorted to. While cholecystotomy is generally recognized as the operation to be aimed at in the treatment of affections of the gall-bladder or bile-ducts, especially in cholelithiasis, it is often impossible to say what operation will have to be done until the abdomen is opened. The indications for operating are:

In frequently recurring biliary colic without jaundice, with or without enlargement of the gall-bladder.

In enlargement of the gall-bladder without jaundice, even if unaccompanied by great pain.

In persistent jaundice ushered in by pain,

and where recurring pains, with or without ague-like paroxysms, render it probable that the cause is gall-stones in the common duct.

In empyema of the gall-bladder.

In peritonitis, starting in the right hypochondrium.

In abscess around the gall-bladder or bile-ducts, whether in the liver or under or over it.

In some cases where, although the gall-stones may have passed, adhesions remain and prove a source of pain and illness.

In fistula, mucous or biliary.

In certain cases of jaundice, with distended gall-bladder dependent on some obstruction in the common duct; but in such cases the increased risk must be borne in mind, as malignant disease will probably be the cause of the obstruction.

If the case be suitable for cholecystotomy, and the gall-bladder and ducts can be cleared without great difficulty by means of forceps within and the fingers outside the ducts, the opening in the gall-bladder can be sutured to the aponeurosis, which is preferable to skin fixation, and drained.

If the ducts cannot be cleared away, cholelithotripsy or crushing of the gall-stones *in situ* by means of the finger and thumb, or by padded forceps, is indicated, an operation which the writer has successfully performed a number of times. This is greatly to be preferred to incising the ducts or fixing the gall-bladder to the intestine.

Choledochotomy, or incising the duct, whether cystic or common, the incision being afterwards sutured,—not an easy matter on account of the depth of the parts to be coapted,—is best effected by means of a rectangular cleft-palate-needle. A drainage-tube should always be inserted into the right kidney pouch in these cases.

Cholecystenterostomy, or the making of an anastomosis between the gall-bladder and intestine, easily effected if the gall-bladder be dilated, with difficulty performed if the gall-bladder be contracted. Mayo has performed this operation three times, with immediate success and recovery in all, and with complete and permanent relief in two. He prefers the method by means of decalcified bone bobbin, which enables the operator to accomplish the anastomosis rapidly, as only two sutures have to be employed.

The daily injection of fluids after an interval of some days, through the cholecystotomy opening, is recommended; this will either soften or dissolve the concretions. Solutions of hot water, taurocholate of sodium, ether, and ether

and turpentine have been used with more or less success. The suggestion to use an injection of olive oil or a five-per-cent. solution of *sapo animalis* or oleic acid is worth a trial.

Cholecystectomy may be required as a secondary operation in cases of stricture of the cystic duct, the common duct being free. On the three occasions on which Mayo excised the gall-bladder, it was for mucous fistula depending on stricture of the cystic duct following gall-stones, and all the cases were completely and permanently relieved.

Cholecystectomy can seldom be advisable or necessary as a primary operation in gall-stones, and extremely rarely possible in malignant disease. In cholecystotomy, where it is impossible to bring the margins of the incised gall-bladder into the wound, and where the parietal peritoneum cannot be tucked down, to meet the edges of the opening a tube is made of the omentum, but no hesitation need be felt in trusting to a drainage-tube, as the peritoneal cavity soon becomes occluded around the drain, and there is little or no tendency to the passage of bile among the viscera, so that a suprapubic drainage opening is quite unnecessary. A vertical incision along the upper part of the right linea semilunaris gives ample room, as a rule, but, if required, a transverse cut may be used.

Suture of peritoneum, aponeurosis, and skin by separate stitches effectually guards against ventral hernia, if the patient be kept recumbent for from twenty-one to twenty-eight days, and if a firm oval pad be worn under a belt for a few months subsequently.

Strict antiseptic precautions should be observed, the abdomen being left as dry and clean as possible.

The author closes his valuable paper with a warning to operators not to attempt these operations without due skill and experience in abdominal surgery, or after witnessing or helping in several operations of this character, as it is impossible to say beforehand whether the case may not prove exceedingly difficult. He also pleads for early operative interference before the patient's strength is exhausted.

#### TREATMENT OF SYPHILIS BY INJECTIONS OF CALOMEL.

LINDEN (*Archiv f. Dermatologie u. Syphilis*, Bd. xxvii., Heft 2) concludes, as the result of an extended hospital experience, that excision of the primary sore of syphilis has a distinctly favorable influence on the course of the disease. This opinion he bases upon six cases. In three

there followed no further manifestations of syphilis; in one the first sign of the disease was manifest two and a half years after excision; in two there were slight transitory phenomena of the disease. Calomel injections occasion much more marked local reactions than salicylate or thymolate of mercury. Abscesses and extensive infiltrations are frequent. Suppuration was rare in the last series of injections. The effect of calomel injections was more rapid than when the salicylate or thymolate of mercury was used. Mercury is given in larger doses during the first course—i.e., the outbreak of secondaries—than for the treatment of recurrences. In eleven per cent. of the cases treated by calomel injections there were no recurrences. In thirteen per cent. of cases treated by thymolate and salicylate, recurrences did not appear. There are fewer recurrences in the first year when calomel is employed, and the interval between these is longer. When the salicylate is employed, the recurrences are somewhat more frequent in the first year, but are shorter and more amenable to treatment, and they were less commonly observed later on in the case. The author concludes as the result of his investigation that, though calomel acts more rapidly than salicylate and thymolate of mercury, the latter preparations are to be preferred, as occasioning less local reaction and as shortening the course of the disease. The calomel may still be employed when quick action is desired.

#### TREATMENT OF ERYSIPELAS.

FELSENTHAL (*Centralblatt für Chirurgie*, No. 16, 1894) has treated thirty cases of erysipelas by superficial and deep scarification, evacuation of the oedematous liquid by means of direct pressure, and rubbing in with the hand a sixty-per-cent. ichthyol ointment or ichthyol solution. Antiseptic dressing is then placed over this, preferably one of iodoform gauze. The details of these reported cases show results no better than those accomplished by much less severe forms of treatment.

#### GASTROPLICTION.

BRANDT (*Centralblatt für Chirurgie*, No. 16, 1894) applies this name to an operation he has devised for the cure of simple dilatation of the stomach. When this condition has been diagnosed, and when an exploratory laparotomy fails to find cicatricial tumors or any obstruction about the pylorus, the surgeon need no

longer close the belly-wall without the hope of affording any relief, but should instead proceed to reduce the stomach to its normal dimensions by taking in tucks at the expense of the muscular and mucous coats, the freely movable mucous layer being not included in the stitches. Silk and gut are used in applying these stitches, and in one reported case tucks were taken in both the anterior and posterior surface of the stomach. The patient recovered, though as to how much benefit resulted the reporter is silent.

#### INTRODUCTION OF AN ARTIFICIAL TESTICLE.

GUIERAS (*American Medico-Surgical Bulletin*, May, 1894) proposes an ingenious operation for the introduction of an artificial testicle. Though not increasing function, this is apparently destined to become highly popular from a cosmetic stand-point. A patient, thirty-two years of age, came to him complaining of the absence of the left testicle and a recurrent right inguinal hernia. The latter was cured by Bassini's operation, after which, at the patient's request and because the absence of the testicle was in fact his main complaint, a mass of celluloid, resembling in size and shape the normal testicle, was inserted into the tunica vaginalis of the left side. The wound required by this operation healed by first intention. The results were apparently entirely satisfactory to all concerned.

#### PAGET'S DISEASE OF THE NOSE.

RAVOGLI (*Journal of Cutaneous and Genito-Urinary Diseases*, vol. xii., No. 140) reports a case of Paget's disease affecting the nose. The diagnosis was based on the presence of large oval shells of a double contour, showing a double margin, filled with abundant protoplasm, which has a strong chromatophoric power. The author concludes that Paget's disease is not limited to the breast of the woman, but can also affect other parts; that the factor of this disease is the presence of certain organisms,—coccidia. It is not an epithelioma, but with time may degenerate into epithelioma.

#### TREATMENT OF PHAGEDENIC CHANCROID.

In response to a letter of inquiry sent out by the *Journal de Médecine de Bordeaux*, No. 8, 1894, concerning the treatment of phagedenic chancroid, ARNOZAN replied that hot local baths sufficiently prolonged gave him excellent

results. This opinion he bases not only on practical experience, but on the researches of Auber, who showed that the pus of chancroid lost its virulence if exposed to a temperature of 39° C., or even of 38° C. if long continued. The baths are thus administered: the region involved should be bathed four to six times a day, according to the gravity of the case, and in water raised to 40° C. The application of this hot water is continued for ten minutes. The hot solution may be either water or 1 to 1000 carbolic or 1 to 10,000 sublimate solution; heat is the important principle. Iodoform is applied in the intervals between the baths. After the granulations have become healthy and the ulcers cease to spread, hot baths should be discontinued.

DUBOURG treats the phagedenic chancroid by cleansing with a 1 to 2000 solution of sublimate. The point of the thermo-cautery is then applied to the entire diseased surface, the statement being made that if the patient is pusillanimous, chloroform may be employed; if not, a .5 per cent. solution of cocaine locally. At times the hot iron is replaced by a solution of chloride of zinc, ten per cent. In whatever way the chancroid has been caused, it is again thoroughly washed with a sublimate solution, dried, and powdered with salol or iodoform. The dressing is completed by pledgets of cotton soaked in a bichloride solution and frequently renewed.

#### ointment FOR THE SKIN-PIGMENTATIONS INCIDENT TO PREGNANCY.

R Oxide of zinc, gr. v;  
Yellow oxide of mercury, gr. xx;  
Castor oil,  
Coca butter, of each, 3iiss;  
Essence of roses, gtt. x.

Apply twice daily; rub into the skin surfaces which show pigmentation.

—*Revue Médico-Chirurgicale de Mal. de Femme*, February 25, 1894; from *L'Union Médicale*.

#### FISSURES OF THE NIPPLE.

R Aristol, ʒiiss;  
Liquid vaseline, ʒi.

This ointment should be applied after each nursing.

—*Revue Médico-Chirurgicale de Mal. de Femme*, February 25, 1894; from *Lyon Médical*.

#### VENTRO-FIXATION OF THE UTERUS.

After reporting some cases of ventro-fixation, SINCLAIR (*Medical Chronicle*, April, 1894) con-

cludes a thorough paper upon this subject as follows:

1. The various published series of cases show that the element of danger is almost *nil*. The present writer's series supports this opinion.

2. The operation, efficiently performed, is a permanent cure of the troubles arising from chronic retroflexion of the uterus, complicated with adhesions or inflammatory affections of the tubes and ovaries.

3. When pregnancy occurs after the operation no distress is experienced by the patient, and no unusual phenomena are observable during pregnancy, parturition, or the puerperal state.

4. Contrary to what might be expected, bladder-troubles are quite the exception after the operation, and these discomforts are almost certainly avoidable by care in operating.

5. In a certain proportion of the cases ventral hernia occurs at the site of the cicatrix. How this is to be prevented is one of the problems of the future.

6. After making full allowance for the element of risk and the incidental drawbacks, the operation of ventro-fixation is not only justifiable, but is indicated in a certain limited class of cases of retroflexion of the uterus with complications.

#### CANCER OF THE RECTUM.

JONES (*Medical Chronicle*, April, 1894), after a careful review of the diagnosis of cancers of the rectum, states that operations have for their aim either the relief of urgent symptoms or radical cure by complete removal of the diseased mass. As a relief measure colotomy affords the best prospect, not only lessening pain, but also checking the progress of the disease and placing the patient in a state of comparative comfort. This operation should be practised before the disease has made serious inroads upon the patient's strength. Linear proctotomy and free scooping away of the diseased mass are methods which have little to recommend them. Removal of the cancerous growth by free use of a scoop or the fingers should perhaps be adopted when other means are unavailable. From recorded cases it appears that, when the diseased masses are thoroughly broken up and taken away, the loss of blood is not conspicuous. In some cases partial cicatrization has taken place. Before operating for radical cure an examination under ether should be made to determine the extent of the disease and the state of the rectum in regard to mobility in the pelvic space. We must also have regard to the general condition of the

patient with respect to strength and nutrition, age must be taken into account, and especially the presence of infiltration of the peri-rectal tissues. Secondary deposits in the liver or elsewhere must be searched for. The immediate risk of the operation is not great. Czerny operated in twenty-five cases with only one death. Causes of death in the majority of cases have probably been cellulitis and peritonitis.

Kraske's method—*i.e.*, removal of the coccyx and the left lower part of the sacrum for the obtaining of sufficient room—is to be commended, the healthy bowel being brought down and fixed in its entire circumference to the skin. The condition of the patient following this operation compares very favorably with that obtained by colotomy. In most instances the patient recovers sufficiently to enjoy life and even to resume active work, and it is possible that the disease may not show itself locally, but return in some internal part where its ravages are less dreadful to witness.

In Cripps's cases nine out of twenty-three recurred after periods varying from four months to two years. These remained well for intervals which varied from two to four years. It is well known that cancer of the rectum remains confined to the gut for a long time, and if the case is taken in hand sufficiently early the chances for successful extirpation are encouraging. Once the disease has travelled beyond the gut, the chances for doing good by removal are of the remotest kind.

#### ORCHITIS COMPLICATING MUMPS.

CATRIN (*Revue de Thérapeutique Médico-Chirurgicale*, March 15, 1894), having had occasion to observe an epidemic of mumps, treated one hundred and fifty-nine of these cases for orchitis. He found that this complication developed from the fourth to the eighth day of the disease, only exceptionally preceding the swelling of the parotid. The orchitis was accompanied by fever, which lasted for three or four days. It usually began in the epididymis, sometimes being limited entirely to this body.

It was best prevented by rest in bed from the beginning of the attack. Atrophy occurs more frequently than is generally believed. Sometimes after a period of wasting the testicle again recovered its normal volume. When the disease developed on both sides, and the testicles atrophied, it was found that the spermatozoa became lessened in number, but did not disappear.

**ASEPTIC DRESSING FOR THE UMBILICAL STUMP.**

ALLEN (*American Journal of Obstetrics*, April, 1894) divides the cord about two and a half inches from the abdomen. After the child is washed, the cord and the abdomen are wiped off with 1 to 1000 bichloride solution; the cord is cut about one and a half inches long and stripped out. The bichloride solution is used freely, a sterile elastic ligature is placed around the cord, and its cut end is touched with a bichloride tablet. A piece of sterile gauze four inches square is prepared by cutting a hole in its centre and saturating it with pure glycerin. In this the stump of the cord is entirely enveloped. It is then turned up on the abdomen, another pad of gauze soaked in glycerin placed over it, and the whole held in place by a sterilized flannel bandage. Cords thus treated fall off in three days. Until this occurs the bandage is opened twice daily and the cord wrapping is saturated with glycerin, the top pad being replaced with a fresh piece of gauze. After the cord falls the umbilical fossa must be filled with aristol, a dry pad of gauze placed over it, and the bandage reapplied. Of course the surgeon should prepare his hands as for a formal operation.

**GASTRO-HYSTEROPEXY AS A SAFE AND RELIABLE MEANS OF CORRECTING PROLAPSUS AND RETRO-PLACEMENTS OF THE UTERUS.**

BOND (*Journal of the American Medical Association*, June 2, 1894) calls attention to the fact that by far the most frequent displacements to which the uterus is liable are the downward and backward,—namely, the various degrees of prolapsus, retroversion, and retroflexion. But few, if any, troubles in the entire field of gynecology impose more of suffering and misery than is entailed by the inflammatory consequences of these affections. The reflex disturbances and the general ill health that usually follow often lead to melancholia, hysteria, and even more pronounced insanity. In many instances the health is wrecked, and the functions of the various systems of the body are so perverted as to lead to a condition of general impairment of nutrition which predisposes to the activity of any inherited tendency to disease.

After discussing the etiology and diagnosis of these conditions, Bond advises the following treatment:

The pessary finds its useful application in

those cases of retroversion and retroflexion in which the uterus is not bound down by peritoneal adhesions, in which the ovaries are not prolapsed and—as is often the case—incarcerated in the cul-de-sac of Douglas, and in those cases in which the displacement has not lasted so long that the round ligaments and other supports have lost all power of regaining their resiliency. In such cases, having first relieved complicating conditions, such as laceration of the cervix and tears of the perineum, we can, by the patient and judicious use of the intravaginal or Smith-Hodge pessary, accomplish much for the relief of our patients; and, recognizing the fact that the displacements usually manifest themselves after parturition, it becomes the imperative duty of the obstetrician to make a careful physical exploration of the pelvic organs within eight or ten weeks after accouchement, with the view to correct any altered position of the uterus. At that period usually the displacement has not produced inflammatory results which would negative the use of the pessary, since such cases generally remain uncomplicated for a variable period of time, often months, save possibly by the results of subinvolution.

The conditions and results of treatment are far different when the displaced organ or associated pathologic state has produced pelvic peritonitis, the adhesive products of which have fastened the uterus, and possibly the ovaries, in varying relations to each other in the cul-de-sac of Douglas, with possibly suppurative results; so also are they different when the suspensory supports, from long-continued traction, have become so attenuated as to be practically paralyzed.

Prolapsus in the first degree can usually be corrected by the use of the pessary, after complicating conditions have been relieved, such as hypertrophy, elongation or lacerations of the cervix, or tears of the pelvic floor; but let the case become once well established, as is represented in the remaining degrees of prolapsus, and we have a condition of things represented by stretched and paralyzed suspensory supports; the cellular tissue is without elasticity; the muscles of the pelvic floor, if not torn, are atrophied and often have undergone fatty degeneration. Under such conditions it is idle to expect anything like complete and satisfactory results from the methods of treatment usually pursued.

In the case of the adherent retroposed uterus pessaries are inapplicable, and forcible breaking up of the adhesions after the method of Schultz, through the uterine cavity, is danger-

ous and often ineffectual. In short, all attempts to interfere with a uterus which is bound down by adhesions, other than through intra-abdominal procedure, are dangerous and to be condemned, for the reason that absolutely accurate knowledge of the pathologic conditions cannot always be ascertained, and in this way we may unconsciously compromise the life of a patient by causing the contents of a pus-sac to be liberated into the peritoneal cavity; and, further, it is a blind procedure, lacking all the elements of precision necessary to reliable and good ends. Here it is that a method of treatment presents itself which is both safe and efficient. This is hysteropexy. Many methods of conducting hysteropexy have been devised. Through it, in a sure and reliable manner, we place the uterus so that its posterior surface is opposed to intra-abdominal pressure, which, as previously stated, acts from above and behind in such a manner as to assist in maintaining the proper position of the uterus. We thus supply the key-stone to the arch of uterine retention, without which in no uniformly reliable manner can the damaged pillars of support be made adequate to their requirements. It is remarkable how little force is necessary to keep the uterus antiposed when anchored ever so slenderly in its proper place.

The general precautions pertaining to a coeliotomy having been observed, the opening through the abdominal wall is made as low down as practicable, and no larger than necessary to admit of efficient and expeditious work. The patient is placed in Trendelenburg's position, by means of which the pelvis is freed from the confusing presence of intestines and omentum, and they are spared the injury of unnecessary manipulation. The walls of the incision are held outward and apart, to admit of as free inspection of the pelvic organs as possible. By means of inspection and the sense of touch, accurate knowledge of the conditions and relations of the pelvic structures is obtained. If adhesions exist, they are broken up by means of the index and middle fingers; the ovaries and Fallopian tubes are brought up to the abdominal opening and carefully inspected, and if found to be seriously diseased they are removed, otherwise not. Small ovarian cysts are treated by clipping off a portion of the cyst-wall. The fact that the organs are found adherent is not in itself sufficient justification for their removal. Next, the uterus, having been lifted to the front, is seized through its fundus with a double tenaculum and held by an assistant in such relation to the abdominal wound that the operator can readily pass a

curved needle threaded with a heavy chromicized catgut suture through all the tissues of the abdominal wall except the skin, embracing sufficient of them to secure a firm hold, then through the anterior and upper portions of the fundus and out similarly through the abdominal wall at the opposite side of the incision. The tenaculum is now removed and the assistant takes the catgut suture in its stead. The abdominal wound is then closed by interrupted sutures in the usual manner, with this difference, that the catgut suture that has transfixed the uterus is tied before, but not until the abdominal suture in closest relation to it has been drawn upon, so as to approximate the peritoneal surfaces. The tying of this last abdominal suture draws the skin over the catgut suture and thus buries it. This has been the author's method of operation, and the results have been uniformly good.

#### SUTURE OF THE MEDIAN NERVE.

CAILLET (*Gazette Médicale de Paris*, May 26, 1894) presented before the Surgical Society a patient who had received a wound of the anterior surface of the forearm dividing the muscles, tendons, and the median nerve. Five days later the tendons and nerve were sutured. At the time of suture there was complete anæsthesia of the entire area supplied by this nerve. Three days after operation sensibility returned in the palm of the hand; in nine days sensation was restored to the index and middle fingers, with the exception of the terminal extremities. At the time of reporting there was still slight dyæsthesia of the terminal extremities of the index. The functions of the hand were entirely restored, and, with the exception of slight wasting of the thenar eminence, there were no trophic changes.

#### ANTISEPTIC VALUE OF TRIKRESOL.

REED (*St. Louis Medical and Surgical Journal*, June, 1894) states, as a result of his laboratory experiments for the purpose of testing the antiseptic value of trikresol, that this agent in one-per-cent. solution kills pus-germs within thirty seconds; one-third per cent. does not kill in two hours' exposure. One advantage of this agent is that the presence of albumin in the fluids to be disinfected does not interfere to a marked extent with its germicidal action, though Reed's experiments showed that when blood-serum is used as a culture agent a minute and a half is required to kill the staphylococci and streptococci. The poisonous qualities of

the drug are about the same as carbolic acid, but it must be borne in mind, in comparing a carbolic acid and trikresol solution, that a one-per-cent. solution of the latter accomplishes as much as four- or five-per-cent. solutions of carbolic acid, hence the danger of poisoning is necessarily reduced four- or fivefold.

It possesses marked germicidal powers, both in watery and albuminous fluids, and does not numb or irritate the fingers.

#### *TREATMENT OF CICATRICAL STENOSIS OF THE ŒSOPHAGUS.*

TIETZE (*Deut. Med. Woch.*, 1894, No. 1617, quoted by *British Medical Journal*, No. 1743, 1894) concludes, as the result of his studies of this subject, that gastrostomy should be done in severe cases more often than it has been in the past, that continuous dilatation with the drainage-tube is more rapid and less dangerous than with bougies, and that combined gastrostomy and œsophagotomy may lead to success in some cases.

#### *INTESTINAL APPROXIMATION.*

MURPHY (*Medical Record*, June 2, 1894), after a careful study of this subject, quotes one hundred and thirty-four intestinal approximations by all methods reported in the last six years. Of these, forty-nine were end-to-end, sixty-one side-to-side, and in twenty-four the position of approximation was not stated. There were forty-four cases of approximation for acute obstruction, with twenty-nine recoveries and fifteen deaths, a mortality of 34.1 per cent. For chronic obstruction, forty-three cases, with thirty-one recoveries and twelve deaths, a mortality of 27.9 per cent., making a total for obstruction of eighty-seven cases, sixty recoveries and twenty-seven deaths; mortality, thirty-one per cent. The methods employed in acute obstruction were: suture, twenty-eight; recoveries, eighteen; deaths, ten; mortality, 35.6 per cent. Mechanical means, thirteen; recoveries, ten; deaths, three; mortality, 23.1 per cent. Suture, with mechanical aid, three cases, with one recovery and two deaths; mortality, 66.7 per cent. Methods employed in chronic obstruction were: suture, twenty-eight cases; nineteen recoveries, nine deaths; mortality, 32.1 per cent. Mechanical means, thirteen cases; eleven recoveries, two deaths; mortality, 15.4 per cent. Murphy button, twenty cases; nineteen recoveries. Suture, with mechanical aid, two cases; one recovery, one death; mortality, fifty per cent. Total number of intestinal approximations for closure of arti-

ficial anus, thirty-five; twenty-eight recoveries, six deaths, one unknown; mortality, 17.1 per cent. Of these, twenty-four were suture, with eighteen recoveries, five deaths, one unknown; mortality, 20.1 per cent.; seven were by mechanical means, seven recoveries; four were by suture with mechanical aid, three recoveries, one death; mortality, twenty-five per cent.

The author finally concludes that the more rapidly the operation is performed the less the danger from shock.

The less the manipulation and exposure of the intestine the less the danger of infection, post-operative paralysis, and adhesions.

The more uniform and continuous the pressure at approximation the greater the assurance of adhesion and the less the liability of infiltration.

A line of approximation is as good as half an inch.

Mechanical means in the last five years have produced better results than the suture in both lateral and end-to-end approximation.

The mortality in end-to-end approximation is much less than in lateral apposition, and should always be given the preference.

The more perfect the juxtaposition of the various layers the less the interposition of fibrous tissue and the more complete the regeneration across the line of union.

The juxtaposition of the similar histological layers of the wall of the intestine is an assurance against cicatricial contraction.

The more extensive the approximation surface, the larger the fibrous deposit, the greater the contraction.

The contraction with end-to-end is less than with lateral approximation.

#### *AMBULATORY DRESSINGS IN FRACTURES.*

BARDELEBEN (*Medical Press and Circular*, May 23, 1894) reported to the German Surgical Congress one hundred and sixteen fractures of the lower extremities successfully treated with walking dressings or splints. Eighty-nine were of the leg, twelve compound; twenty-two of the thigh, five compound. The patient was able to get out of bed and go about on his broken limb in a few days. He could devote himself to his business and his family, and was saved the muscular atrophy of decubitus. His appetite, digestion, and sleep were those of a healthy individual. The ambulant treatment is of special importance in the case of the aged and of drinkers. The fractured bones heal more rapidly than if kept at rest. In fracture of the thigh the chief support must be

tuber ischii, in the lower leg the condyles of the tibia. Great care is required. If there is marked swelling, it is better to wait three or four days; but when the dressings were applied earlier, no harm resulted. If much swelling is present, however, the dressings generally have to be reapplied. A gelatin plaster-of-Paris bandage was used, with iron bands to give the required firmness. A morphine injection is desirable before applying the dressing, but no anæsthetic. The first attempts at walking should be made with a go-cart, on the principle of that used in teaching a child to walk. All the cases began to walk the day after the leg was put up, and they persevered until they could walk with crutch and stick, and later on with a stick only. A single putting up is generally sufficient.

#### TREATMENT OF PERSISTENT URETHRAL DISCHARGE.

FULLER (*Journal of Cutaneous and Genito-Urinary Diseases*, vol. xii., No. 141), after alluding to the cases of gleet which no treatment benefits, states that he has cured a certain number of these cases by regularly milking the seminal vesicles. During the active stage of treatment patient should be seen once in every five to seven days; this active stage lasts from one to nine months. When there is marked inflammatory reaction, treatment may be frequently suspended from three to six weeks. Stripping is done with the forefinger in the rectum, and to carry this in to a sufficient depth considerable perineal pressure is frequently required. In applying this treatment the patient stands with his body bent forward; then the foot of the operator corresponding to the hand to be aided is placed in a chair, thus bringing the knee up to the level of the elbow. By this arrangement the muscles of the thigh and leg, as well as of the arm and shoulder, all working together, can furnish pressure sufficient to overcome the resistance of the most rigid perineum. It is only occasionally that such extensive muscular efforts are called for. In weak, loose-fibred individuals, little or no pressure is required to reach the vesicles. Indeed, a counter-abdominal pressure can easily engage the tip of the forefinger in the sigmoid flexure.

#### TREATMENT OF STRICTURE OF THE OESOPHAGUS.

MAYO (*Northwestern Lancet*, April 15, 1894) reports two cases of stricture of the oesophagus. The first, a child three years old, burned by lye one year before, was treated by bougies.

These, though they did not pass through the stricture, seemed to give temporary relief. Later, narrowing became almost absolute; gastrotomy and retrograde dilatation were practised. These, when supplemented by an œsophagotomy, rendered the passage of a silk thread from the stomach to the neck wound possible; this was used to saw through the stricture. Dilatation was accomplished by knots placed in the second thread and brought through the narrowing. For a month this process of division was carried on every four days, and perforated shot were clamped upon the threads and brought through. At the end of this time bougies could be passed first to the neck and then through the mouth. The child's convalescence from this time was practically uneventful.

A second child, aged four, swallowed lye a year before coming under observation. Only after prolonged effort could a filiform bougie be passed through the lower and deeper of the two strictures. At the end of a year a fair amount of dilatation was accomplished; but no further progress being possible by this method, œsophagotomy was performed. The upper stricture was readily dilated by forceps; the lower stricture was carefully nicked with a dull knife on a grooved director and dilated with forceps, permitting of easy catheterization of the œsophagus.

#### TREATMENT OF FACIAL ERYSIPELAS.

WHALEN (*Journal of the American Medical Association*, April 29, 1894) treated some cases of facial erysipelas with guaiacol, and reports satisfactory results. He especially calls attention to the short time that elapsed in his reported cases between the application of the drug and the resulting relief. Repeated trials on the fourth case showed that a chill could be aborted by the external application of guaiacol. Except in cases of extreme irritability of the skin, the application of pure guaiacol does not cause pain. In such cases the guaiacol may be diluted with alcohol, olive oil, or any of the fixed oils to the desired strength. The amount of guaiacol employed varied from 20 to 30 minims. In two cases the application of the remedy was followed by subnormal temperature. He considered that convalescence was hastened in cases in which he used the drug, and that this is the most efficient therapeutic agent that we possess at the present time. The author ordered the drug painted over the affected areas, and noted in all cases immediate

relief of distressing symptoms, though the eruption itself did not seem to be materially influenced.

#### TENORRHAPHY BY MEANS OF WIDE CATGUT SUTURES.

EMANUEL J. SENN (*Journal of the American Medical Association*, vol. xxii., No. 17) reports a case of tendon suture, interesting because the divided tendons could not be closely approximated, but were made continuous by the insertion of a number of catgut sutures. In this operation the original method of Gluck was followed. This author held that the catgut, properly applied, prevents the tendon ends from retracting, forms a passage-way for tissue proliferation, establishes a barrier by which the embryonal cells secure protection from atrophy caused by pressure of surrounding parts, and acts as a foreign body, stimulating the matured cells. The patient reported suffered from extensive lacerated wound on the back of the forearm. This was closed and healed, but left the fingers supplied by the extensor communis digitorum absolutely useless so far as extension was concerned. Three months later an attempt was made at restoration. On opening the old scar the proximal end of the common extensor tendon was found. This, properly speaking, was not a tendon, but simply the end of the muscle. After tedious dissection, the four distal extremities—i.e., the three tendons of the extensor communis digitorum and the extensor indicis—were discovered some four inches lower down the arm. Splicing by splitting was not to be thought of; therefore medium-sized catgut was employed, eight sutures connecting the tendons and the muscle. No drainage was applied; the external wound was closed with an interrupted row of silk-worm sutures and a continued row of catgut. Hæmorrhage had been well effected by ligature and hot-water irrigation. The hand was dressed in an extended position upon an anterior splint. The dressing was removed upon the fourth day, and the wound presented a favorable appearance, except for a small suppurating focus around one stitch. The twelfth day the patient could extend three fingers upon the splint with slight effort. At the end of a month he had complete restoration of function.

#### TREATMENT OF COMPOUND FRACTURES.

CRILE (*Medical Record*, February 10, 1894) holds that, no matter how extensively bone is injured, in the absence of other complications

this constitutes no ground for amputation. The fragments should be thoroughly reduced and, if necessary, held in place by strong silk ligatures, which may be fixed in the grooves, may be a saw, may be cut off close and allowed to remain buried in the wound. The fracture should be treated the same as simple fracture, but in case of infection provide for ample dependent drainage. In case of doubt, treat the case as if it were known to be infected. Restore the normal relations of the soft parts, if necessary, by means of buried sutures. If there are ragged edges, the wound should be revised by trimming off the crushed tissues, and if the opening in the skin be soiled, continuous excision of the margin should be practised. If necrosis of the bone follow, maintain free drainage and wait for a complete separation. Unless under continuous observation, plaster-of-Paris bandage should not be applied until the acute symptoms have subsided and the condition of the wound has declared itself. In restoring the normal function, persistent treatment by massage, baths, tonics, and, possibly, electricity, are important. The bone should be treated as if there was no injury to the soft parts; the soft parts as if there was no injury to the bone.

#### SUCCESSFUL REIMPLANTATION OF URETER INTO THE BLADDER.

MAYO (*Medical Record*, February 10, 1894) reports the successful reimplantation of ureter into the bladder for the relief of utero-vaginal fistula, the result of vaginal hysterectomy. The first effort at restoration was unsuccessful, but later the urine in the bladder and that escaping from the wounded ureter was drained off by a rubber tube, and about this was formed a channel, resulting in complete closure of the fistula in two weeks.

#### RECTAL INCONTINENCE AND ITS CURE BY TORSION.

GERSTER (*Medical Record*, vol. xlv., No. 6), basing his procedure on the ingenious method of Gersuny as applied to the incontinence of urine in women, successfully operated on a boy for incontinence of fæces. It will be remembered that Gersuny, for the cure of vesical incontinence in women, dissected out the entire female urethra, rotated it around its own axis, and secured it to this position by pressure of the outer skin. This resulted in perfect continence. Gerster thus treated the patient brought to him. The latter was a boy seven years of age, with prolapse of the rectum and inconti-

nence of fæces, due to congenital defect of the sphincter. He was born with an imperforate anus, for which proctoplasty had been performed shortly after his birth. The child was anæsthetized, and two and a half inches of the lowermost portion of the rectum, including all of its coats, were freely dissected out. The free margins of the gut were secured at the four quadrants of its circumference by four artery clamps, and then twisted in an arc of three hundred and sixty degrees, and secured to the outer skin by a dozen silk sutures. Both prolapse and incontinence were cured.

#### THE OPEN INCISION IN UNCOMPLICATED CASES OF HYDROCELE.

CLENDENIN (*Boston Medical and Surgical Journal*, vol. cxxx., No. 18), basing his opinion on the experience of two cases, holds that open incision is the only operation for simple hydrocele of any size, and that by the aid of cocaine anæsthesia this procedure may be made comparatively painless. It is worthy of note that both the author's cases recovered in a comparatively short space of time. After calling attention to this, Clendenin characterizes the practice of paracentesis and injection of an irritating fluid as unsurgical, basing this opinion upon an experience of one case. This case disappeared immediately after operation. Contrary opinions expressed by Agnew and Wyeth are mentioned with due tolerance.

#### AFTER-TREATMENT OF OPERATIONS FOR APPENDICITIS.

BURRELL (*Boston Medical and Surgical Journal*, May 3, 1894) secures the stump of the appendix where there is but little pus. When suppuration is free he employs catgut. He eschews drainage and prefers three rows of abdominal stitches,—one in the peritoneum, one in the transversalis fascia and muscles, and the third in the skin. He employs silk for the simple sutures.

His treatment for shock consists in the use of alcoholic stimulants, brandy, whiskey, heaters, and rectal enemata of brandy, atropine, strychnine, and digitalin. He administers cracked ice, beef-tea, and a little milk for the first twenty-four to forty-eight hours. Opiates are used freely, as he believes the patient loses more from pain than he gains by the free action of the intestines from saline cathartics. He claims to have lost one patient through the injudicious use of salines. He controls vomiting by cracked ice and morphine, soda and cham-

pagne. In one instance washing out the stomach at the end of three days caused vomiting to cease. Where this distressing symptom continues beyond the third or fourth day, the author usually regards the case as hopeless. Salines are indicated when, after the first forty-eight hours, there is any increase in the frequency of the pulse or glazing of the tongue. Where there has been vomiting, saturated solution of salts may be given by enema, though the same result may be attained by glycerin suppository. No reason is seen why opium and saline cathartics should not be given at the same time. Sterile water or boracic-acid solution are employed for flushing out the cavity of the appendicitis operation. The wound is always closed without drainage when there is no pus, or even if there is a slight amount of pus, if this can be cleansed away it is safe to close. Rubber tubes are employed when there is a large pus-cavity with walls which do not collapse; rubber dam or iodoform gauze are indicated where the cavity is collapsible. Iodoform gauze should always be employed for drainage when, appearing within forty-eight hours of the beginning attack, a perforating appendix is found, especially when it is a question whether the general peritoneal cavity is infected. There seems to be a feeling on the author's part that the appendix should always be removed. Reopening of the wound or thorough exploration of it is strongly advocated in the event of long-continued profuse discharge, progressive rise of temperature after the fifth day, or chill owing to failure of drainage. In three instances where the author had been compelled to reopen wounds between the tenth and twelfth days after the temperature had been normal, this interference being required on account of sudden and continued rise of temperature and chills, there escaped, on separating the coils of intestine, a large quantity of offensive gas, but no pus. In each instance the wounds were repacked, the temperature fell to normal in a short time, and convalescence was established.

#### METHODS OF DRAINAGE, WITH SOME REMARKS ON A NEW ASEPTIC DRAINAGE-TUBE.

HYDE (*Brooklyn Medical Journal*, May, 1894) calls attention to the fact that ever since drainage of the abdominal cavity was first proposed as a safeguard against septic troubles or hemorrhage, there has been constant experimenting to find the best means to accomplish this result, and many ingenious devices have been submitted to the profession for approval.

With the exception of Mikulicz's method of drainage by iodoform or sublimate gauze, which method is still in vogue to some extent, all others seem to have been abandoned practically for the glass tube. This is probably because it is one single glass piece, perfectly smooth, and the most easily rendered aseptic.

Any method by which the fluids likely to be found in the abdominal cavity after operation can be brought to the surface is drainage, and good as far as it goes, but all are found to be faulty in one respect or another.

A strip of gauze may not irritate the peritoneal coat, but one cannot be assured that it remains *in situ* fifteen minutes after the wound is closed: it may be anywhere except where needed,—in the bottom of the wound. Rubber tubing or any soft, flexible material is no better; nor are the drainage-tubes made from animal tissues, which soften down, collapse, or are absorbed, any better.

For this reason the drainage-tube must be of some firm material,—hard rubber, aluminum, or glass,—of such make and shape that no doubt can be entertained as to its position in the wound, and the general consensus of surgical opinion is that glass is preferable.

In conclusion, the writer introduces a new drainage-tube, devised and perfected by himself. Iodoform or sublimate absorbents can be freely used with it, yet never come in contact with any of the abdominal tissues to produce irritant or toxic effects. It seems to possess a higher absorbent power of fluids than other means of drainage known, and its presence in the wound and abdomen seems to be less harmful. This drainage-tube consists of a double glass canula, curved to fit the wound and the locality of the operation. It has four eyelet-holes on either side for any pus or exudate to enter. It has a continuous and uniform calibre throughout its course, through which the sterilized and absorbent wicking is drawn, several inches at necessary intervals, thus pumping out all deleterious matter and keeping the wound dry and clean.

The wicking is boiled for two hours in water, then dried and placed in ether. It is then put in a hot biniodide solution, or it may be sterilized, after boiling in water, by an ether and iodoform mixture. It is then dried between layers of aseptic cheese-cloth and wound on spools, which are also equally protected. The spools are placed in aseptic boxes, with a rubber tube attachment to each, through which the aseptic wicking is conveyed to the drainage-tube. This connecting tube is about fifteen inches long, to allow the spool to lie by the

side of the patient in bed. A double fold of iodoform gauze can be used in place of a rubber tubing to protect the wicking. It is necessary to have a few extra spools of wicking prepared for emergencies, and the canula can always be easily threaded by first tying a shot to a piece of stout silk and passing this through the canula, and afterwards attaching the silk to the wicking. Finally,—

1. It is narrower than the usual drainage-tube, and it conforms to the line of incision.
2. It is impossible for the tissues to clog the openings and thus defeat its intended purpose.
3. It forms a complete pump, which removes all pus, blood, or serum.
4. It is absolutely aseptic.
5. It can be safely intrusted to any intelligent nurse without danger to the patient.
6. The surgeon can always know what is going on at the bottom of the wound.
7. It is very light and strong.
8. There is no danger of fæcal fistula resulting from its use.

## Reviews.

---

ESSENTIALS OF NERVOUS DISEASES: A MANUAL FOR STUDENTS AND PRACTITIONERS. By John C. Shaw, M.D. Second edition, revised.  
Philadelphia: W. B. Saunders, 1894.

When the first edition of this little book upon nervous diseases was published, we took pleasure in commending it, for it is a good compilation of the subject of which it treats, provided that the purchaser desires a book which of necessity is so condensed that it but gives him the outline of the subject. The second edition differs in no way from the first, and very little new material has been added to it. The book is one of the best of the series of which it is a member.

ESSENTIALS OF ANATOMY, ARRANGED IN THE FORM OF QUESTIONS AND ANSWERS. By Charles B. Nancrede, M.D. Fifth edition.  
Philadelphia: W. B. Saunders, 1894.

We are told in the preface of the fourth edition that since 1888 fifteen thousand copies of this useful little manual have been purchased by students and others, and we see no reason why its popularity should not continue. While too brief to form a dissecting manual and far too brief to act as a text-book of anatomy, it is useful to the student who desires from week to

week to go over the more salient points about which the more minute points must be clustered. The frequent editions have eradicated errors and enabled the author or his assistants to keep the book up to the mark.

URIC ACID AS A FACTOR IN THE CAUSATION OF DISEASE. By Alexander Haig, M.A., M.D., F.R.C.P. Second edition.

London: J. & A. Churchill, 1894.

Those readers of the THERAPEUTIC GAZETTE who have been subscribers for more than a year or two may perhaps remember the laudatory review which we took pleasure in publishing of the first edition of this very notable contribution to modern pathology and medicine. In that review we took pains to set forth some of the opinions and views of Dr. Haig. The present volume is not only a reprint of the earlier edition, but has been benefited by the incorporation of the results of the author's many additional studies, and should be in the hands of every practitioner of medicine; for although it is probable that we may have to modify some of the views expressed by Dr. Haig, he occupies the position of being a pioneer in this interesting subject, and his careful and conscientious work entitles whatever he may contribute to literature to careful study.

AN INTERNATIONAL SYSTEM OF ELECTRO-THERAPEUTICS: FOR STUDENTS, GENERAL PRACTITIONERS, AND SPECIALISTS. By Horatio R. Bigelow, M.D., and thirty-eight associate editors. Thoroughly illustrated. In one large royal octavo volume.

Philadelphia: The F. A. Davis Company, 1894.

This system, published in one volume and edited by Dr. Bigelow, deserves a large amount of success. The articles which it contains not only deal with the medical aspects of electricity as we recognize them to-day, but also present a large number of scientific facts in regard to which the general physician should be informed, including certain historical views which are of value to the worker in modern medicine. A valuable chapter is the opening one by Professor Duff upon electro-physics, in which, in the space of three hundred and eight pages, he gives about as complete a *résumé* of electricity, medical and otherwise, as can be found in any single book. Another interesting chapter is that by Wesley Mills, of Montreal, upon animal electricity, and still another that by Dr. A. P. Brubaker upon electro-physiology. The important subject of electro-diagnosis is treated by Dr. W. F. Robinson, of Albany; and, as might be expected, the influence of

electricity upon diseases of the uterus is discussed by Dr. Massey. It is impossible to go over each individual article and analyze it. Suffice it to say that the volume presents the subject of electricity in medicine in the favorable light which medical electricians are so fond of throwing upon it. Even if some of us are unable to believe that such extraordinarily good results follow the application of electricity to all conditions, every one recognizes the extraordinary value of this remedial agent when properly applied, and all of us should know when and how to apply it. This book presents the information in such a form that no one can have an excuse for pleading ignorance concerning the use of electricity in the treatment of disease.

AN AID TO MATERIA MEDICA. By R. H. M. Dawborn. Third edition, revised and enlarged. By Wolsley Hopkins, M.D.

New York: G. P. Putnam's Sons, 1894.

This is an exceedingly condensed quiz book, syllabus, or summary of modern materia medica, interleaved for additions by the student. In the back portion of it is a list of the newer unofficial drugs which is quite complete and interesting, but we fail to see how the book can be of great value to students, except those who are attending a course of lectures in which the lecturer follows an arrangement such as here given. The size is small octavo and the number of pages one hundred and thirty-three.

THE TREATMENT OF TYPHOID FEVER. By D. D. Stewart, M.D.

Detroit: George S. Davis, 1894. Price, 25 cents.

The very excellent work which Dr. Stewart is capable of doing and has already done is a guarantee that this little volume will prove interesting reading. Its contents consist of four chapters,—the prophylaxis of typhoid, the general management of a case, specific and antiseptic treatment, and the treatment of special symptoms and complications,—a summary which gives a very good idea to the reader of the ground which is covered by the book. The very latest ideas from the most prominent members of the profession are quoted with sufficient fulness to provide the purchaser with the information he desires, and while there are a few typographical errors, the general excellence of the medical advice is such as to guarantee the success of this little handbook.

## Correspondence.

## PARIS.

(From our Special Correspondent.)

There being such a multitude of large hospitals in Paris, I found some difficulty in visiting many of them. There are no fewer than seventeen thousand hospital beds within the city limits, besides numerous dispensaries attached to the hospitals and also separate from them. As the chiefs are very uncertain in their visits, much time is wasted in trying to see the clinics, so I contented myself by "following," as it is termed, a few of the best-known operators.

Paris can boast of but few well-built, or what is commonly called modern, hospitals, the Cochin approaching more to the pavilion plan; some of its buildings, however, are very old. Hôtel-Dieu is considered their best, but I think few would call it a very good model. The Necker is, to my mind, a better institution, with some very good modern improvements, especially the venereal clinic and the operating amphitheatre, while of the Salpêtrière, Saint-Louis, Charité, and Laennec nothing but their size can recommend them.

At the Necker is the most complete arrangement for the study of gonorrhœa to be found in Europe. The clinic is under the charge of Professor Guyon, while the out-patients' department is conducted by Dr. Ganet.

Each case is thoroughly examined physically and the discharges microscopically before treatment is given, careful histories taken, and all changes in treatment recorded. As the daily clinic is large, the statistics from such a place should be exceedingly valuable and reliable. The irrigators proposed by Professor Guyon are in constant use, both in acute and chronic gonorrhœa and in cystitis. The liquid is placed one and one-half yards (or metres) above the bed or table upon which the patient lies, and the force thus obtained is sufficient to convey the liquid into the bladder, a small glass tip at the end of the rubber tube being held firmly in the meatus.

In this manner he uses the potassium permanganate treatment. From one to two litres of a watery solution of potassium permanganate, in varying strengths, from 1 to 4000 to 1 to 1000, depending upon the stage of the disease, are passed into the bladder once or twice daily, the patient raising himself to a sitting posture and emptying his bladder from time to time. In this way the bladder may be thoroughly

irrigated without the passage of a catheter, which, in cases of stricture, will often be of considerable advantage.

In the same way solutions of silver nitrate (1 to 1000) and of sublimate (1 to 5000) are used in cystitis. Professor Guyon also uses stronger solutions of silver nitrate (one per cent. to five per cent.) and of cupric sulphate (two per cent. to seven per cent.) in obstinate cases of gonorrhœa.

One very important thing taught here is the absolute cleanliness in the use of instruments. Each patient's genitals are washed with boracic acid, the instruments kept in carbolic or boracic solutions, and all instruments are carefully cleansed as soon as used. In this way they have been able to avoid those troublesome complications occasionally seen in dispensaries where such care is not taken.

After about two years' use of the permanganate treatment, Professor Guyon is so well satisfied with it that he invariably commences treating in this way every case of acute gonorrhœa that comes to his clinic.

The use of plaster splints in fractures prevails in most of the hospitals. Professor Ferrier, at the Bichat, applies plaster at once, leaving an opening or slit down the front, holding the splint in place by tying with a bandage in three or four places; while Professor Duplay, at Hôtel-Dieu, cuts away part of the splint or cast, leaving two lateral strips about two or three inches wide, which are held in place by a roller bandage, or sometimes strips of rubber plaster; he adds oiled silk to the dressings before applying the splints. The early resort to massage is considered very essential, Professor Ferrier commencing on the tenth day.

Dr. Pozzi, at Hôpital-Broca, has now practised cauterization of painful ovaries for over two years, and considers the plan very successful. In one case, in which he operated upon both ovaries, the woman has since given birth to a child.

He performs his laparotomies in the ordinary recumbent position; draws the ovaries out of the abdominal opening. If the ovary is totally diseased, he removes it; but if a part is found to be healthy, he amputates the affected portion, cauterizes the stump, then sews the end with silk. If there are some small cysts, he opens them by touching with the Paquelin point. The ovary being returned to the abdomen, he examines and treats the other in a similar manner. Often as many as six small cysts are opened in this way in each ovary. In cases of hysteroplasty he attaches the ante-

rior surface of the uterus to the abdominal wall instead of the fundus, claiming better results if the uterus becomes pregnant.

Dr. Chaput, at Salpêtrière, operated upon a case of patellar fracture of four months' standing, in which there was almost two inches retraction. After cutting away the lateral attachments, he was obliged to cut the patellar tendon to effect apposition. The fractured surfaces being sawed away, he perforated each fragment in two places, passed silver wire through, and in turn drew back through the same opening by means of the wire strong braided silk ligatures. These being tightened and tied, apposed the two fragments, the ligaments, muscles, and skin being sewn as nearly as possible in their former relations; the knee was loosely dressed and the patient returned to bed without a splint. He commences passive movements in eight days, and allows the patient to leave his bed after four weeks. This is the third case he has treated in a similar manner, the other two recovering with useful limbs.

Lucas Championnière, at Saint-Louis Hospital, performed lately his sixteenth operation upon the kidney. In this case, which was for floating kidney, he used his own modification of the Reverdin needle, and very quickly and easily sutured the capsule to the abdominal wall. He drains with large quantities of iodoform gauze, and over this places bags of lint or gauze containing what he terms the Saint-Louis sachet powder, the formula for which I give below, thinking it might prove useful to some one who wishes a cheap and very good substitute for iodoform. It is composed of equal parts of iodoform, powdered cinchona, benzoin, and magnesium carbonate.

In cases of laparotomy where the intestines are exposed for some time, as in a recent case of hysterectomy, he employs the carbolic spray, and where there is a suspicion of infection he uses a four-per-cent. solution of carbolic in the abdominal cavity.

M. Péan, at the International Hospital, still following the old custom, operates in full dress. Although he does some general surgery, the most of his work is confined to gynecology. He still operates almost entirely without the ligature, and in vaginal hysterectomies he sends the patient to her bed with as many as fifteen forceps in her vagina, the remaining space about the instruments being filled with iodoform gauze.

M. Péan also uses an electrical machine for drilling and sewing. The power is taken from the lighting apparatus. The table on which it rests can be approached to the bed or table,

and is quite a time-saving as well as a labor-saving appliance.

The Reverdin needle is in pretty general demand among the French surgeons, doing away almost entirely with the use of the needle-holder. They employ the curved and the straight, the latter being almost always used for skin-suture. Chloroform is the almost universal anæsthetic employed. By means of a special bottle it is administered in very small quantities. M. Chaput uses bromide of ethyl, and some surgeons still prefer the A.-C.-E. mixture. M. Ferrier administers several gallons of oxygen gas after each operation. I did not see ether given once.

Antisepsis is still much more frequently employed than asepsis; in fact, Dr. Ferrier is the only one I have seen who carries out the principles of asepsis. He uses gauze for sponging, keeps his instruments dry in sterile trays covered with gauze or towels, but sometimes employs solutions of boracic acid. He prepares the patient with soap and water and a sterile towel, pulls out the umbilicus with toothed forceps, and carefully scrubs in abdominal cases. Most surgeons, however, employ the following method: green soap, dry towel, ether, alcohol, and sublimate (1 to 2000), in the order given.

PARIS, FRANCE, May, 1894.

#### CASTRATION FOR HYPERTROPHY OF THE PROSTATE.

To the Editors of the THERAPEUTIC GAZETTE:

DEAR SIR:—May I ask the privilege of putting on record in your columns a statement as to a matter which may some day be of more or less surgical interest?

In December, 1892, I requested one of my assistants (Dr. Kirby) to make a series of experiments on dogs, with a view to determining whether or not castration would be followed by notable atrophy of the prostate. The thought that this was possible had been suggested to me by the comparison long ago made by Velpeau and afterwards by Sir Henry Thompson between the prostatic and the uterine fibromyomata.

Control observations as to the weight of the normal prostate in dogs were begun at once. The first castration was done January 27, 1893; the others followed at intervals of a few days. The results, showing atrophy, first, of the glandu-

lar and then of the muscular elements, were so decisive that I embodied in a paper I was then writing the suggestion that castration might be a valuable therapeutic measure in many cases of hypertrophied prostate. So far as I know, the suggestion had never before been laid before the profession.

I subsequently learned of the observations of John Hunter and Owen, and the confirmatory investigations of Mr. Griffiths, as to the changes in and out of the rutting season in the prostate of the mole, hedgehog, and other animals, and as to the effect of castration in various species. Griffiths's observations appear to have been confined to animals already castrated for other reasons; no definite series of experiments is mentioned. He maintained, moreover, that the enlargements of the gland were not to be classed with the uterine fibro-myomata. His paper, which was written to demonstrate that the prostate is in its essential significance a sexual and not a urinary organ (a subject which has long been under discussion), contained a few illustrations taken from various sources of atrophy of the prostate in eunuchs. I found, in addition, a note by Harrison, that in cases of sterility in the male the prostate had been shown to be atrophied.

No reference existed in surgical literature to any possible application of these facts to the treatment of cases of hypertrophied prostate, but they strengthened me in my decision to bring the matter up for consideration.

I read the paper in Buffalo, N. Y., on June 1, 1893, before the American Surgical Association. Abstracts were published during June in most of the medical journals of this country. On August 1 it was published in its entirety in the *Annals of Surgery*, and on September 9 a full abstract appeared in the *British Medical Journal*, that part of it relating to castration being unabridged. Since June, 1893, the following communications relating to the subject have appeared:

*Centralblatt für Chirurgie*, No. 35, September 2, 1893.—Ramm, of Christiania, reported two cases operated on earlier in the year, with marked improvement.

*Ibid.*, No. 17, April 28, 1894.—The same writer gives the dates of his operations as April 3 and April 25, 1893, and reports a practical cure in each case.

*British Medical Journal*, September 16, 1893.—Mr. C. Mansell Moullin wrote that "the question of castration as a means for procuring involution of the enlarged prostate, raised by Professor J. W. White in his address to the American Surgical Association, deserves more

than passing consideration," and stated that he had discussed it with a patient in November, 1892. He adds, that "one single instance in which definite reduction in size was proved to have taken place would be of incalculable value."

*Ibid.*, September 23, 1893.—Mr. Reginald Harrison wrote, "As bearing upon the correspondence that has followed Dr. White's remarks on castration in preventing growth of the prostate," that the suggestion had been made to him by a patient some years ago, and that, as a compromise, he had subcutaneously divided the vasa deferentia. He knew no more of the course of the case, except that the patient was alive and well six or seven years later.

(In the discussion that followed the reading of my paper in Buffalo, Dr. Mears asked if division of the vasa deferentia might not accomplish the same result as castration.)

*Ibid.*, September 23, 1893.—Mr. MacMunn suggested that the sexual history, past and present, of the subjects of enlarged prostate be more freely studied, as well as the conditions of the gland in different races of men and the lower animals.

*Ibid.*, September 30, 1893.—Mr. Moullin again called attention to the importance of getting definite information as to the effect of castration upon the abnormally-enlarged gland in aged persons, as he says that it must now be regarded as an established fact, not only for animals, but for man, that "castration in early life prevents the full development of the prostate, and in adult life causes the normally-developed gland to atrophy."

*Ibid.*, September 30, 1893.—Mr. Griffiths called attention to Ramm's cases, and added, without allusion to my paper, that "this method of treatment is no doubt likely to suggest itself to any one who has studied the nature and function of the prostate in its relation to the sexual function." He said further that it may in some cases prove an effectual remedy, but went on to call attention to the lack of proof that prostatic enlargement depends on sexual excitement.

*Ibid.*, May 12, 1894.—The same writer called attention to his own letter of September 30, and sent a translation of Ramm's latest reports of his two cases, already alluded to.

*Ibid.*, November 18, 1893.—Mr. Arthur Powell described a case which he said might "be of interest in connection with Professor White's recent address," and in which a patient with retention of urine from enlarged prostate, having undergone removal of the

right testicle for a nodule and having a small left testicle, became impotent, and obtained relief from all his urinary symptoms. Rectal examination showed "marked diminution in the size of the prostate."

*Medical News*, Philadelphia, December 30, 1893.—Dr. Francis L. Haynes, of Los Angeles, Cal., announced his first operation; this was followed by two others.

In the *Buffalo Medical and Surgical Journal*, March, 1894, he thus describes his cases: "White's Operation: Orchectomy for Hypertrophy of the Prostate." Following the suggestion of Professor White, of Philadelphia, I have three times made double castrations in old men afflicted with prostatic hypertrophy. 1. Operation eighty-four days ago, in a case of two years' standing, of moderate severity. The patient is practically cured. 2. Operation forty-seven days ago, in a desperate case, requiring catheterization every two hours, complicated by intense cystitis and by morphinism acquired as a result of frightful suffering. With the most devoted nursing, this old man has improved wonderfully. Cystitis has disappeared; one-third of the urine is passed spontaneously; catheter is used every four or five hours; morphinism has been cured; general condition good. 3. Operation fourteen days ago. Incipient case; catheterization almost impossible because of the peculiar development of the prostate."

In a fourth case, section of the vas deferens gave no definite results.

During Christmas week, 1893, I saw, in consultation with Dr. F. Fremont-Smith, at St. Augustine, Fla., an apparently hopeless case of hypertrophied prostate with marked sepsis, cystitis, beginning uræmia, etc. I advised a trial of castration, as the condition forbade any direct attack upon the prostate. Dr. Fremont-Smith has just reported the case in a paper read before the Genito-Urinary Section of the New York Academy of Medicine. The patient fifteen weeks after operation had gained forty-five pounds and has no symptoms of cystitis or other urinary trouble; he urinates freely and normally.

On January 31, 1894, I operated on a medical man, aged sixty-nine years, who had a very large prostate, about half the size of an orange; who had passed no urine except by catheter for years; whose urine was loaded with mucus, was offensive, and at short intervals was filled with blood.

At this time,—fourteen weeks later,—while he has not yet urinated spontaneously, rectal examination shows a reduction of the size of

the prostate to about its normal dimensions. The catheter, which formerly was introduced for nine and a half inches before reaching urine, now goes in only eight inches, when urine begins to flow. Its introduction is easy and painless instead of difficult and very painful. No blood has appeared in the urine for two months. The urine itself is entirely normal in appearance, odor, and in all other respects. I have during this time suggested the operation to three other patients, all of whom have declined it on account of my frank statement that it was yet in the experimental stage and that no *promise* of benefit could be given.

The idea seems to have occurred vaguely to several persons, but certainly no one had made it public or even formulated any distinct suggestion in regard to the matter prior to my paper.

Ramm's cases, though not published until between three and four months after my paper, appear to give him the operative priority in Europe, while Haynes undoubtedly did the first operation of the kind in this country.

This, so far as I know, is the evidence existing on this subject up to this date. It would certainly seem to establish the claim of the operation to further and much more extended trial, and it shows, I think, that even on a basis of experiment and theory alone I was justified in suggesting it to the profession.

I am, etc.,

J. WILLIAM WHITE.

PHILADELPHIA, U.S.A., May 25, 1894.

#### TREATMENT OF TOBACCO HABIT.

To the Editors of the THERAPEUTIC GAZETTE:

DEAR SIRs:—I send you with this a prescription which I have found very useful in the treatment of the tobacco habit, and which, I trust, may interest the readers of the THERAPEUTIC GAZETTE:

R Gold and sodium chlor., gr.  $\frac{1}{4}$ ;  
Strychninæ nit., gr.  $\frac{1}{16}$ ;  
Nitro-glycerin, gr.  $\frac{1}{16}$ ;  
Atropinæ sulph., gr.  $\frac{1}{16}$ ;  
Tinct. digitalis, ℥iij;  
Capsicum, gr.  $\frac{1}{4}$ ;  
Salicin, gr. i;  
Cinchonidinæ sulph., gr. i.  
For one pill.

### URETHRAL CARUNCLE; CURETTING FOR ABORTION; PESSARIES.

CLINICAL LECTURE DELIVERED AT THE JEFFERSON HOSPITAL,  
OCTOBER 31, 1893.

BY E. E. MONTGOMERY, M.D.,  
Professor of Clinical Gynecology, Jefferson Medical College;  
Gynecologist to Jefferson and St. Joseph's Hospitals;  
Obstetrician to Philadelphia Hospital.

**G**ENTLEMEN:—The first patient I bring before you is a young woman with a projection from the orifice of the urethra. This has been troubling her for some length of time,

and has been associated with much pain and distress. She has been treated in the hospital before for nervous disease, and it is quite possible that this growth may have had something to do with it. This growth is known as a urethral caruncle; it affects the urethra, is papillary, arising from a thickening or localized inflammation of the mucous membrane of the urethra, probably begins in a gland, the duct of which becomes occluded, causing the wall to be thickened and form an obstruction, thus leading to its extrusion. The growth becomes abraded, leaving a red, strawberry-like mass,

sometimes protruding from the orifice of the urethra; its nerve-terminations are exposed, rendering it extremely sensitive. Passage of urine over it produces severe, agonizing pain. Its projection from the orifice of the urethra causes it to be frequently irritated by the clothing, by pressure, and it is a source of pain during coition. It may sometimes be situated some distance up the canal, requiring the urethra to be dilated for its complete removal. In some cases a number of growths may be present. Treatment consists in taking a pair of forceps, drawing the growth down, and snipping it off with scissors. The base may be cauterized with nitric acid or with the actual cautery. Before proceeding to treatment, however, it is quite important to keep in mind the fact that not every protrusion from the urethra is necessarily a caruncle, as we may have a prolapse of the wall of the urethra in which the orifice will be seen in the centre of the prolapsed portion. The excision of such a mass would mean the cutting out of the entire section of the urethra, and almost certain resulting stricture. Again, we may have the bladder wall prolapsed through the urethra, or, in other words, a vesical hernia, so that this condition must also be eliminated before we resort to operative procedure. Pressure against the urethra with the finger, or the introduction of a catheter or bougie, will be sufficient to determine its true character. In removing a caruncle, as in every operation about the genital tract, we are careful to have the parts thoroughly clean to avoid danger of infection. We want the wound to heal up as quickly as possible. If the parts are kept clean it is not likely to give rise to any serious trouble. Healthy urine flowing over the part does not injure it. As a germicide or disinfecting agent, we are using at present in this clinic a solution of oil of cinnamon, taking one drop of oil of cinnamon to the ounce of distilled water (1 to 500). The effects of this agent have been carefully investigated in the laboratory of the college and also in the private laboratory of Dr. D. B. Kyle, who has devoted much attention to it. It is found in this strength to be a very effective germicide. Dr. Kyle's theory is that the oil of cinnamon, like all volatile oils, coagulates or contracts the protoplasmic envelope of the germ and thus imprisons it in its contracted shell, rendering it inert. As the agent has been tried effectively in the laboratory, we propose to make some clinical studies with it, and feel certain that if it is satisfactory it will be far preferable to the germicides we are now using, as the bichloride, on account of its poi-

sonous character, cannot be used in the peritoneal cavity. In addition, it is a source of danger, from the possibility of the solution being mistaken and used for other purposes. The oil of cinnamon gives a very fragrant odor, and in the strength of 1 to 500 reddens the skin and causes it to tingle. It is free, however, from poisonous effect, and, if necessary, could be used in the abdominal cavity without danger. Now, having carefully cleansed the parts, seized this growth with a pair of forceps, and snipped it off close to its base, we find that considerable bleeding results. In the excision of large masses, bleeding not infrequently is free. It can, however, be readily prevented by packing gauze tightly into the vagina, making pressure upon the urethra, and with a pad pressing the urethra firmly against the symphysis. The patient will be permitted to void her urine, as the evacuation of the urine will be attended with less danger and discomfort than would be the use of the catheter. If it is necessary to use the catheter, the parts should be carefully sponged first with a disinfectant solution before the catheter is introduced, and the latter should be a glass one which has been carefully disinfected and kept in a disinfectant solution during the intervals of its use. It will not be amiss for me to say at this juncture that you cannot observe too great care in the use of the catheter, and for whatever purpose it may be required, it should be the rule to carefully cleanse the vestibule before it is introduced. For this reason I would advise you to discard the old procedure of introducing the catheter by touch, as by inspection you are better able to see that a clean instrument is passed through a clean surface, and the slight offence to the modesty of the patient does not compensate for the danger of infection of the urethra and bladder and the long-continued suffering resulting from a urethritis or cystitis.

*Curetting for Abortion.*—The next patient was brought to the house by Dr. Fisher, chief of the clinic, from one of the smaller streets of the city. She had undergone an abortion, and when he called to see her he found a portion of the placenta remaining. She had quite a severe hemorrhage, causing her to present the blanched appearance you now see. Since her admission to the house she has had an elevation of temperature, reaching last night 101° F., indicating that there is some product remaining. We have placed her under an anæsthetic, and have carefully washed the vagina with a solution of creolin and soap, wrapping the finger with gauze in order to thoroughly clean out the crypts and folds. We will proceed to the

dilatation of the cervix and the use of the curette. Now, as I have repeatedly endeavored to impress upon you, in all cases of sepsis, whether arising as a result of abortion or following confinement, the important indication is to thoroughly sterilize the uterus. This is frequently attempted by the use of disinfecting injections; but when we consider that the uterine mucous membrane is covered over with decidua and *débris* that is thrown off from the involuting uterus, we can readily understand that even the most powerful germicides will only act on the surface, while beneath it will remain large colonies of multiplying germs, the products of which are absorbed, producing elevation of temperature and secondary suppurative foci. The disease may extend either through the mucous membrane of the uterus to that of the Fallopian tubes and cause a pelvic peritonitis, or infect the ovaries, producing ovaritis or collections of pus in the tubes; or we may have inflammation passing through the blood-vessels, infecting the uterine sinuses and producing multiple abscesses therein, or secondary inflammations in the larger veins, producing phlegmasia; or it may, again, pass through the lymphatics, producing suppuration in the pelvic lymphatic glands. Through the infection of the blood-vessels we may have large collections of pus in the cellular tissue of the broad ligament while there has been no inflammation of the tubes, or, again, we may have tubes the source of infection,—that is, the infection may travel through the tubes, setting up peritonitis or ovaritis, without having caused inflammation in the tube itself. When we consider, then, the danger to which every patient is subject, and realize that the sterilization cannot be accomplished by irrigation alone, it is incumbent upon us to exercise prompt measures to prevent the infection extending beyond the surfaces already involved. This is best accomplished by carefully dilating the cavity, particularly in abortion, and the use of the sharp curette, going over the entire surface of the cavity, scraping away the *débris*, and either irrigating the cavity through the handle of the curette or following curetting by irrigation, in this way sterilizing the surface as thoroughly as possible and removing the infected material. As we are not always absolutely certain, however, that the curetting has been complete and that some small particles of infected material may not still remain, it is well to provide for the thorough drainage of the uterus, so that the blood resulting from the curetting shall not be retained, again infected, and rendered a source for further propagation of poison. This drain-

age is best accomplished by packing the cavity with iodoform gauze; the pressure of the gauze in the cavity prevents further bleeding, promotes by its capillary action thorough drainage, stimulates by its presence as a foreign body contraction of the uterus, produces a current of serum into its meshes, thus increasing the eliminating power of the uterus, keeps the surfaces apart, and, in addition to drainage, promotes the more rapid decrease of the organ.

Now, in dilating this canal, you will notice that I have used graduated bougies in preference to the parallel-bar dilators. I do this for the reason that dilatation can be accomplished more readily, with less injury to the cervix, as the bougies stretch the cervix on all sides and produce less tendency to laceration. The cervix is held by the volsellum, and for this purpose I use a three-pronged instrument, as it holds more firmly and is consequently less likely to do injury. The uterus is pulled over the bougies. In introducing the bougies it is important to exercise care that they should not, particularly the smaller ones, be used with force, as in weak walls they may puncture the walls of the uterus, as I have had occur in my own experience in two cases, in neither of which did the patient suffer any inconvenience. By the use of these dilators the cervix is distended to the size of the largest number,—43. The curette I use is what is known as the Duke curette, with an opening through the handle, by which, on attaching it to a fountain syringe, a current of disinfecting fluid can play constantly upon the curetted surface, washing away the *débris* as fast as it is scraped off. For the purpose of irrigation through the curette, we use a one-per-cent. solution of creolin in distilled water. As the curetting is done, the finger of the other hand may be passed into the vagina alongside of the cervix, pressing the uterus against the instrument, in this way controlling its action. With the completion of the operation a gauze tampon is carried to the fundus of the uterus, packing it well into the body of the organ for the purposes we have already mentioned. Now, as I pack the gauze into the cavity of this uterus, we recognize that it still continues to bleed, and on looking at it we see we have torn the soft, friable cervix on the right side, probably through the circular artery. In order to prevent further bleeding and relieve the patient of the effect of such a tear, I will introduce a suture here upon the side, bringing together this surface. The gauze is pushed over so that it will not be included in the suture. There is still remaining a sufficient amount of cervical canal to serve

every purpose. The patient will be kept quiet in bed, and permitted to pass her urine, if she can do so; otherwise the catheter will be used. The bowels will be looked after, and the gauze will be removed at the end of three or four days. In considering the progress of infection, we will find that those cases in which the disease is carried into the system either by the blood-vessels or lymphatics are much more active and rapid in their course than where it passes by the continuous mucous membrane. The introduction of the poison through the tube leads to a localized peritonitis and gluing up of the abdominal end of the tube and the consequent localization of the disease. In the blood-vessels, however, this is not so rapidly accomplished, and the poison has the greater opportunity for more thorough dissemination. Localized abscesses may form in the walls of the uterus, and these cases will be characterized by exceedingly high temperature. I remember a case in the Philadelphia Hospital, with a temperature reaching 107° F., only modified by the use of the cold pack. The patient died with a temperature of 108° F. An autopsy disclosed less than a teaspoonful of pus in the uterine sinuses upon one side, which was the only pathological symptom present.

*Pessaries.*—I have here a specimen that illustrates the importance of careful consideration in the use of pessaries. The one I show you is a Hodge pessary, covered over with calcareous deposits from the secretions of the vagina; it was worn eleven years without removal. It was removed this morning in the dispensary service, and was found with this coating. Such a deposit upon a pessary roughens its surface, giving rise to irritation of the mucous membrane and ulceration. If pressure is severe, perforation of the anterior or posterior wall may occur, resulting in a recto- or vesico-vaginal fistula; or the irritation of the pessary may produce exuberant granulations, which may cause it to be completely buried in the tissues. I was called some years ago to see a case of this kind, in which an old woman was suffering from hemorrhage and a very profuse discharge. She was supposed to be suffering from malignant disease. Upon examination, I found the small end of a pessary projecting, the posterior bar of which was buried in tissue to the depth of more than half an inch and firmly fixed. As it would have required considerable dissection to cut the pessary out, I preferred to draw it down upon one side and with a pair of bone-pliers cut through it. This was done on the opposite side and the remaining portion pulled

out of the track. The patient recovered, and, it is needless to say, the condition for which the pessary was used was also cured, though this is not a plan of treatment for prolapse I would recommend. In the Philadelphia Hospital some years ago I removed a glass pessary from a woman who had worn it for thirteen years. The pressure of the pessary had given rise to a cicatricial ring immediately beneath it, so that only a small portion of the pessary could be exposed. It was removed by passing a pair of fenestrated forceps arranged something like obstetrical instruments, so that one blade could be passed after the other. After the forceps were applied, it required considerable work to deliver the pessary. Unless you have an instrument specially devised, the removal of these glass pessaries is attended with considerable danger of their being broken. A case occurred in the Philadelphia Hospital in which a glass ball was broken in an old woman, causing perforation of the bladder and a vesico-vaginal fistula high up in a cicatricial canal that was exceedingly unfavorable for operative procedure. The result was increased suffering and distress to this old lady. An accident of this kind occurred to the late Dr. Levis, of this city, who immediately packed the vagina with plaster of Paris, covering over the glass, and after this had become firm and hard, the whole mass was removed, thus saving the surface from being injured by the glass.

#### THE TREATMENT OF EMPYEMA, WITH SELECTED CASES.

BY J. WILLIAM WHITE, M.D.,

Professor of Clinical Surgery in the University of Pennsylvania;  
Surgeon to the University, Philadelphia, and German Hospitals.

AND

ALFRED C. WOOD, M.D.,

Assistant Surgeon to the University and Gynecean Hospitals;  
Instructor in Clinical Surgery in the University of Pennsylvania.

IN its broadest application an empyema is a collection of pus in one of the natural cavities of the body. As usually employed, however, it refers to a purulent collection in the pleural sac, and it is here used in this sense. Among the common causes of this condition are a previous pleural effusion which has become purulent, or as occurs in the course of various infectious diseases, the collection may be purulent from the beginning. Occasionally an empyema may result from an hepatic abscess which has perforated the diaphragm, from a pulmonary abscess which has discharged through the pleura, or from an abscess elsewhere which has found its way into the pleura. Finally, it

may result from a fractured rib or a penetrating wound of the chest.

Fluid collections in the pleural sac may accompany, besides pleurisy, simple and tuberculous pneumonia, pulmonary tuberculosis, and typhoid fever. The exudation in these cases is serous or sero-fibrinous, and may remain in this condition or may become purulent. In the light of our present knowledge, the change from the serous to the purulent condition must be explained by the invasion of micro-organisms.

The bacteriology of this subject has received considerable attention in recent years. As the result of his investigations, Bewley (*Dublin Journal of the Medical Sciences*, 1890) makes the following classifications of empyema:

1. Those cases in which ordinary pyogenic micrococci make their way into the pleural sac through an opening in the chest-wall or from the lung, by the bursting of a pulmonary abscess, or gangrene, into the pleural cavity.

2. Those cases occurring in connection with croupous pneumonia and caused by pneumococci.

3. Those occurring in persons afflicted with phthisis, and which are tubercular.

4. Those cases in which, under various circumstances, pyogenic micrococci are able to enter and live for some time in the tissues of the body without doing harm.

5. Those cases which are a part of a general pyæmia.

Coplick (*Archives of Pediatrics*, 1890) records his results of careful bacteriological investigations of twelve cases of empyema in children. These cases are divided as follows:

1. Those in which the bacterioscopic results are not uniform and the micro-organisms found not diagnostic.

2. Those in which he was able to establish the presence of the pneumococcus of Fränkel and Weichselbaum in the purulent exudate.

3. Empyema occurring in tubercular subjects.

4. Those cases in which a focus of suppuration situated outside the chest can be pointed to with a degree of probability as the possible source of infection. He arrives at the conclusion that a large proportion of empyemas in children follow or complicate processes in the lung of an acute character.

Parmenter (*Buffalo Medical and Surgical Journal*, January, 1894) quotes the classification of Courtois-Suffit, which divides cases of purulent pleurisy into (a) pure and (b) mixed forms. The first class includes,—

1. Empyema from the pneumococcus. This is said to form twenty-five per cent. of the

purulent pleurisy of adults and fifty per cent. of the same affection in children.

2. Empyema from the streptococcus. This is the common microbe of suppuration.

3. Empyema from the bacillus tuberculosis.

4. Empyema due to the encapsulated bacillus of Friedländer and to the typhoid bacillus of Eberth. These forms are said to be rare.

Mixed forms include,—

1. Empyema due to the pneumococcus and the streptococcus together.

2. Empyema due to the typhoid bacillus and the streptococcus.

3. Empyema due to the bacillus tuberculosis and the streptococcus, or to the staphylococcus, or both together.

4. Putrid or gangrenous empyema. In addition to the streptococcus and the staphylococcus, the micro-organisms of putrefaction are present.

It will thus be seen that a number of competent independent observers, after carefully-conducted experiment, have arrived at practically uniform results,—namely, the demonstration of the constant presence of microbes in empyemas. It is a question whether those cases in which the pneumococcus or the bacillus tuberculosis only are found should be classed as strictly purulent collections, although the fluid may be turbid from admixture of fibrin and leucocytes. It is more in harmony with what is known of this process elsewhere to consider the purulent process to be due to the presence of pus microbes alone or to a mixed infection.

It will be, perhaps, impossible clinically to classify many of the cases that are observed, but this does not seriously modify the treatment which should be instituted. The previous history will, of course, have an important bearing in many instances. If we know, for example, that an attack of pneumonia, influenza, or typhoid fever has preceded the pleurisy, and if there is no other cause to explain its presence, an etiological relation may be inferred, or if the patient is known to have previously suffered from pulmonary tuberculosis, it is reasonable to suppose that the case is of this nature.

The symptoms of purulent pleurisy may develop suddenly, but more frequently the onset is insidious, in which case the pleural collection is very apt to be overlooked unless this possibility is borne in mind. There is, however, usually fever of an irregular type, pain in the chest, cough, and dyspnoea on exertion, although any or all of these may be wanting.

The diagnosis is to be made by eliciting the usual signs of fluid in the chest and deter-

mining the character of the fluid by the exploring-needle. It must be borne in mind that the physical signs, like the symptoms, may be obscure, but by a careful examination of the chest a mistake will be infrequent. This, of course, is always to be confirmed by hypodermic puncture.

An empyema may terminate in spontaneous cure by absorption of the fluid, in perforation of the lung and expectoration of the collection, or by perforation of the chest-wall. This termination is very rare, however, and the condition, if unrelieved, tends to a fatal issue.

*Treatment.*—The presence of pus in the pleural cavity having been detected, the use of drugs is not to be considered, except in so far as is made necessary by the general condition of the patient.

The different methods of operating for the relief of this condition have been classified by Steele as follows:

1. Aspiration.
2. Aspiration and antiseptic irrigation.
3. Thoracocentesis with trocar and canula.
4. Thoracocentesis, with subsequent drainage.
5. Simple incision.
6. Incision and drainage.
7. Incision, with through-and-through drainage, with or without the addition of antiseptic measures.
8. Subperiosteal resection of a rib and drainage.
9. Thoracoplasty (Estlander's operation).
10. Perflation.

A pleural effusion having been recognized, if of recent formation, and if the patient's strength be good, careful aspiration with aseptic precautions may be done. If the effusion is one of long standing, and if the patient's condition is one of hectic, showing that the blood is already poisoned from absorption, then free drainage must be at once instituted. If the needles used in the aspiration are surgically clean, it need not be feared that on account of the puncture, if the fluid reaccumulates, it will assume a more unfavorable character than before. Should the accumulation return, then a more radical operation becomes necessary for its relief.

A review of the literature of the subject impresses one with the marked diversity of opinion still existing in the profession regarding the relative merits of the several procedures enumerated. For example, Immermann (*Deutsche Med. Woch.*, 1887) advocates simple aspiration, and objects to costal resection on account of the resulting deformity. He considers Bülow's siphon drainage, or aspiration drain-

age, the ideal treatment. This method is also highly endorsed by Powel, Curschmann, Runneburg, and others.

Steele, on the other hand, has collected one hundred and twenty-one cases treated by aspiration (*Journal of the American Medical Association*, 1888). Of these, but twenty-three (nineteen per cent.) were cured, six died, and the balance were sooner or later subjected to a more radical treatment, usually incision.

Mader, Rogée, Rochelt, and Williams have devised special valvular tubes, which are intended, when introduced in the chest-wall, to allow the escape of fluid from the pleural cavity, but to prevent the entrance of air. In all of these methods the dominant idea is to withdraw the fluid without allowing the ingress of any air into the pleural sac.

Even conservative writers generally concede, however, that when the chest contains pus, nothing short of thoracotomy will suffice to meet the indications present. The operation is a simple one, and may be performed quickly and safely, barring the danger which may attend the rapid withdrawal of a large collection of fluid from the pleural cavity. No attempt need be made to prevent the entrance of air within the chest. The results of this operation have been very good, as is attested by many reported cases. For instance, Griffith (*British Medical Journal*, 1887) reports fifty cases treated by this method. Of these, thirty-five recovered, five were discharged with sinuses still open, and six died, three from already advanced phthisis.

Owing to difficulty in securing free drainage by simple incision, frequently on account of the close proximity of adjacent ribs, costal resection to accomplish this object has been advised and practised by a large number of surgeons. This allows of very free drainage and, if need be, intrathoracic exploration, without adding anything to the dangers of simple thoracotomy. The results obtained by costal resection are much better than by the other methods described. As an example of the utility of this operation the experience of Holsti may be quoted. This author reports (*London Medical Record*, 1887) twenty-seven cases of empyema operated on by excising a portion of one rib, followed by the introduction of two drainage-tubes; of these, twenty-four recovered, two were discharged with a fistula, and one was under treatment at the time of making the report. Among others who employ this method may be mentioned Schede, Pel, and König.

Finally, Estlander advocated the resection

of portions of several contiguous ribs. This method is especially applicable to those chronic cases in which the lung has little or no tendency to expand after the withdrawal of the fluid. Many cases are reported which attest the value of this operation. The object aimed at in Estlander's thoracoplasty is, by removing portions of several ribs, to allow the chest-wall to retract to meet the more or less collapsed lung, and, by the formation of adhesions, to secure obliteration of the pleural cavity. To be successful, a sufficient number of ribs should be resected to accomplish the desired result. Böckel reports a case in which he removed portions of seven ribs and part of the scapula; the patient recovered and improved in health. He says that want of success in this operation is due to too great timidity on the part of the surgeon.

Richelot and Moreau, following Quenu, have performed section of the ribs, without removing any portion, to secure the sinking in of the chest-wall, as follows Estlander's operation. It would not appear that this method possessed any advantage over the latter, while it must be less certain in its beneficial effects.

The position of the opening is a matter upon which most authors lay considerable stress. Sutherland (*Lancet*, London, January 27, 1894) differs from this view, and states that the selection of the point for the introduction of the drainage-tube may be made quite apart from any considerations of drainage. The emptying of the pleural cavity, he contends, is not due to the action of gravity, but to the forcible expulsion of the fluid by the expansion of the lung and the pushing up of the diaphragm. If these are secured, he says, the fluid will be driven out irrespectively of the position of the opening, and such arrangements as a dependent opening or two openings are quite unnecessary. There will usually be no contraindication, however, to opening at a low point, and we believe that this plan will be followed more uniformly by good results.

The other methods of treatment mentioned have nothing to recommend them and need not be further considered.

That no one operation will be uniformly indicated in every case of empyema will be accepted without argument, but a tendency towards overdue conservation has certainly existed. The safety of a patient does not always lie in doing the least that is possible. We know that with imperfect drainage in empyemas, as in all other collections, sinuses remain indefinitely and continue to secrete pus, thus exposing the patient to the danger of amy-

loid degeneration of the viscera. It may be put down as established, that in those cases in which sinuses persist, the drainage has been imperfect. Osler ("Practice of Medicine," 1892) pertinently says, "It is sad to think of the number of lives which are sacrificed annually by the failure to recognize that empyema should be treated as an ordinary abscess, by free incision." Such a commentary from so distinguished an authority should awaken both physicians and surgeons to a proper appreciation of the necessity for early and free drainage. Another common error results from the mistaken conception of "free drainage." It is a not infrequent experience to see cases in which, in spite of alleged free drainage, improvement is not observed, and upon investigation it is found that the drainage *did not drain*. There are few affections in which surgery can claim greater success than in empyema. It is not uncommon to observe a patient pale and exhausted by his long illness, with cough, irregular fever, clammy sweats, and lost appetite, become free from fever and sweats, and regain his appetite, color, and strength after having properly drained a long pent-up empyema. That operation is, therefore, indicated which will give the freest exit to the purulent collection. Küster employs the following method: Following exploratory puncture, an incision is made in the fourth or fifth interspace, anteriorly; a silver sound is introduced through the opening and carried to the deepest part of the pleural sac, posteriorly. The point of the sound is pressed against the chest-wall until it can be felt in an intercostal space, when the rib above is resected. A long drainage-tube is passed through both openings, and the chest-cavity washed with a weak salicylated water.

It is desirable to remove the drainage-tube as soon as can be safely done, in order to secure the healing of the external wound and the expansion of the lung. To promote the latter, during the entire course of treatment and for a considerable period thereafter pulmonary gymnastics should be systematically carried out. This may be conveniently done by making forcible straining efforts, whereby the air in the healthy lung is forced into and expands its fellow. The same object is very well accomplished by having the patient force water by expiratory efforts from one bottle to another, the bottles being arranged after the manner of Wolff's bottle.

Küster's plan is probably unnecessarily heroic, although, if the patient's strength were not too far exhausted, no harm would come

from the second opening. This plan has not been adopted, however, in the cases recorded, but care has always been taken to establish the freest drainage. The operation is equally indicated in both extremes of life and the presence of fever is not a contraindication.

The question of irrigating the pleural cavity after the operation has been the subject of much discussion. It has been our practice to irrigate the pleura until the fluid came away clear; no harm has seemed to us to follow this procedure. Cases are recorded, however, in which sudden collapse or convulsions have occurred during the irrigation. Bowditch strongly objects to irrigation in empyema: first, because it is unnecessary, in his opinion; and, second, because it is not free from danger. He says that he has only once thought it necessary to irrigate in three hundred and ninety-nine operations. De Cérenville, Runeberg, Robertson, Basel, and Bonberet hold the same opinion.

The following technique for resection of the ribs seems to us to best meet the indications:

1. The portion of the rib selected for removal should be that between its angle and sternal attachment. Posterior to this it is more immovable and situated so closely to the adjoining ribs that the difficulties of the operation are greatly increased.
2. Those ribs between the third and the tenth should be selected which most accurately overlie the cavity.
3. The number of ribs operated upon should be proportionate to the extent of the cavity.
4. The length of the pieces excised should be proportionate to the depth of the cavity.
5. The operation should be done aseptically and subperiosteally, and when so performed is almost without danger; and even in cases where large portions of ribs are removed is followed by no permanent loss of function in the external respiratory muscles of that side.

It should be unnecessary at this time to insist upon the usual antiseptic details employed in modern surgery. Without this precaution the character of the discharge is apt to be unfavorably influenced by the entrance of other micro-organisms than those already present.

The ribs may be exposed by an incision parallel with and upon the rib, but it is less satisfactory than the method of making a curved incision exposing the portion of rib to be excised. This incision is the more desirable when portions of two or more ribs are to be removed, as it obviates the necessity of making multiple incisions. The periosteum is to be separated from the rib by the ordinary ele-

vator, and by keeping the latter close to the under surface of the rib the intercostal artery may be separated with the periosteum and thus escape injury.

Free drainage is best obtained by introducing the ordinary pure rubber drainage-tube, which should, however, be of ample size. Some method must be employed to prevent the escape of the tube in the pleural cavity, where its subsequent detection and removal would be difficult, while the presence of the tube in the chest would keep up the very condition which its original employment was intended to relieve. A satisfactory method for retaining the tube is to stitch it to the margin of the wound. Another method consists in using a flat disk of hard rubber, with a hole in the centre corresponding in size with the calibre of the rubber tube, one end of which may be split into three or four portions, which are to be stitched to holes in the disk. The drainage-tube should be covered over with a liberal dressing of iodoform gauze or other antiseptic material. The subsequent treatment should consist in changing the dressing as frequently as necessary, and where there are no contraindications we believe it desirable to irrigate the cavity at each dressing. For this purpose a saturated solution of boric acid is perhaps the best. If the fluid is of a pronounced purulent character, the use of hydrogen peroxide in full strength or diluted will be beneficial. It should not be employed, however, if the opening in the chest is not large enough to give free exit to the gas which is formed, otherwise it is possible that a sufficient degree of pressure might be caused to interfere somewhat with respiration and circulation.

Attention should also be given to the general health of the patient. A sufficient quantity of easily-digested food should be administered. The hypophosphites, cod-liver oil, iron, and arsenic may one or more be indicated. An out-of-door atmosphere and the direct rays of the sun are also important.

The question of the removal of the tube is frequently difficult to decide; the general rule is, however, to gradually shorten it as the cavity contracts.

The only contraindications to costal resection would appear to be advanced pulmonary phthisis or an empyema complicating a general pyæmic state.

Age has no bearing on the indications of the operation. Cases are reported which have been successfully operated upon in the first year of life, and the same is true of advanced years; in both instances the presence of retained pus

is a more serious condition than the effects of the operation.

The following cases have been selected from those occurring in Dr. White's practice:

**CASE I.—*Empyema; Incision; Imperfect Drainage; Resection of One Inch of the Fifth and Sixth Ribs; Recovery.***—C. M., aged fifty-three years, farmer, gave the following history: Eighteen months previously, following the influenza, the patient had pleuro-pneumonia, which confined him to bed for three months. During this time and for about a year subsequently he had persistent loose cough with considerable expectoration. About a year after the beginning of the present illness the patient complained of pain on the right side on coughing, and soon afterwards an abscess appeared between the seventh and eighth ribs of that side. This was incised and a large quantity of pus evacuated, with almost complete relief of the cough. The discharge continued to be quite free, and during the past few weeks the cough has again increased in severity. The patient has lost fifteen or twenty pounds in the past year. Nothing in the family history had any bearing in the case. The patient had never been strong.

As there was evidently imperfect drainage, it was decided to resect portions of the fifth and sixth ribs in the anterior axillary line. For this purpose a horseshoe-shaped incision, with the base upward, was made, exposing these two ribs, and about one inch of each was removed subperiosteally. On incising the pleura, about a pint of pus was evacuated. The cavity was freely washed out with warm boric-acid solution, a large drainage-tube introduced and secured by stitching to the skin incision, the margins of which were approximated, and a liberal antiseptic dressing was applied. During the next week the cavity was syringed out three times daily with warm boric-acid solution. The patient was up in a chair on the sixth day, and walking about on the eighth day. There was at this time very little discharge, the cavity being now irrigated but once daily. The cavity gradually contracted, the patient's health improved, and by the seventeenth day the chest would hold but two-fifths as much as it did immediately after operation. In this condition the patient returned to his home under the care of his physician.

**CASE II.—*Empyema; Costal Resection; Recovery.***—V. E., aged twenty-five years, came to the hospital on account of pain in the right side of the chest, and dyspnoea. There was nothing in the family history or in the personal history of the patient which had any bearing

on the present illness. The first symptom was noticed a year ago, with pain in the right chest, dyspnoea, and cough. Inspection showed the right chest to be distended and motionless and the intercostal spaces bulging; as drugs failed to reduce the effusion, the chest was aspirated eleven times; at first the fluid was clear, but at the fifth aspiration it was turbid, and at the subsequent tapplings was distinctly purulent. During all this time the patient had fever of an irregular type, cough, and dyspnoea; he was confined to bed much of the time, but was usually able to get about for a short time after each tapping. In this condition he was brought for operation. Upon inspection the right side of the chest was seen to be bulging, the intercostal spaces obliterated, and there was a tendency to pointing in the seventh interspace in the mid-axillary line. Percussion gave a flat note and the overlying skin was oedematous.

A curved incision with the base upward and the lower part corresponding with the seventh interspace was made in the axillary line and an inch and a half of the seventh rib was resected subperiosteally. About one hundred ounces of purulent fluid were evacuated. The cavity was irrigated with sublimate solution (1 to 20,000), a large drainage-tube inserted, and the wound closed with sutures; a liberal dressing of antiseptic gauze was applied. On the fourth day the patient was allowed to sit up, the appetite was good, strength improved, and recovery was in every way satisfactory.

**CASE III.—*Empyema; Estlander's Operation; Recovery.***—F. S., aged twenty years, came to the hospital on account of an old empyema which had lasted four years. The patient suffered from an attack of pneumonia twelve years ago, from which he had evidently entirely recovered. Four years ago he had a second attack of pneumonia, following which empyema developed. The chest was aspirated and a large quantity of purulent fluid was withdrawn; the collection rapidly reformed, and a second aspiration was performed. As the fluid reaccumulated a small drainage-tube was introduced and allowed to remain for five or six weeks. At the end of this time it was withdrawn and the external opening closed. It was necessary a year later to reopen the wound and introduce another drainage-tube; this tube disappeared, and it was thought entered the pleural cavity. Another tube was put in its place, which had been retained up to the time he came under Dr. White's care; a constant discharge had kept up. It was decided to perform Estlander's operation in order to secure the heal-

ing of the cavity. Portions of the sixth, seventh, eighth, and ninth ribs were resected. A careful search for the missing tube with the finger failed to disclose it; the cavity was then irrigated with sublimate solution (1 to 20,000) and packed with strips of iodoform gauze; the wound was then covered by a thick dressing of antiseptic gauze. The patient bore the operation well. The packing was removed on the second day after the operation. There was a large collection of fetid pus, and with this a portion of drainage-tube six inches in length was discharged. This was curled up in a round mass and held in this position by lymph. The tube had probably been encapsulated, and the packing had caused this to break down, which resulted in the discharge of the tube. The convalescence of the patient was rapid and satisfactory. The lung gradually expanded, and at the end of two weeks had nearly filled the cavity of the chest on that side. At the end of a month the cavity was so small that a tube could no longer be introduced, and the second incision was, therefore, kept open by a tent of iodoform gauze; the patient at this time was going out every day. A week later he was discharged, having entirely regained his health and the wound completely healed to the level of the surface, and requiring but a few more days for cicatrization.

CASE IV.—*Empyema; Estlander's Operation; Recovery.*—F. M., aged thirty-three years, was suffering from a large empyema which filled the whole left side of the chest, for which it was decided to resect portions of the fifth, sixth, and seventh ribs, which was done through a large horseshoe-shaped flap. Two inches were removed from the fifth rib, two and a half inches from the sixth rib, and three inches from the seventh rib. The subsequent treatment was the same as in the other cases. The health and strength of the patient rapidly improved and the cavity diminished in size; but, owing to the impossibility of control of the patient, a sinus persisted, which, however, did not interfere in any way with the usual occupation. Death occurred two and a half years later from an acute intestinal affection.

CASE V.—*Empyema; Costal Resection; Recovery.*—R. S., aged twenty-one years, was suffering from a large empyema which had followed a pneumonia. After it was found that the medicinal treatment would not induce the absorption of the fluid, the chest was aspirated. The accumulation rapidly recurred, and as the condition of the patient was becoming one of hectic, the necessity for securing free drainage was imperative. To secure this it was deemed

necessary to remove portions of the sixth and seventh ribs. A large quantity of fluid was evacuated, and free drainage established by means of the rubber tube. The improvement in the general condition of the patient was immediate and progressive. The task of transferring water from one bottle to another by means of blowing through a tube which perforated a cork accurately adjusted to the mouth of the bottle was begun early; the drainage-tube was removed in the fourth week, when a small tent of iodoform gauze was used in the external opening until the cavity became obliterated.

### THE UTILITY OF AMPUTATIONS NEAR THE ANKLE.

CASES EXHIBITED AT THE MEETING OF THE PENNSYLVANIA  
STATE MEDICAL SOCIETY AT PHILADELPHIA,  
MAY 16, 1894.

BY GWILYM G. DAVIS, M.D., M.R.C.S.,  
Surgeon to the German and St. Joseph's Hospitals.

IN 1889, before the Philadelphia County Medical Society, Dr. Mordecai Price, of this city, advocated the abandonment of all amputations near the ankle-joint, and substituting therefor amputation below the knee.

In his address on surgery before this Society in 1891, Dr. Allis also advocated the same procedure.

In 1892, Dr. Price again brought up the subject, and now at this meeting he once more presents a paper advocating the same procedure.

These gentlemen are not alone.

Dr. Buntz (*Medical News* February, 1894), Professor of Surgery in the Wooster University, Cleveland, Ohio, has lately written in the same strain, as has also Mr. Truax, an instrument-maker of Chicago.

Dr. Mordecai Price has been most outspoken and it was on account of his proposing again to read a paper on the subject before this meeting that I was induced to collect some cases which it was thought might throw some light on it. I have simply gathered such as I could without any intention of showing extraordinary results.

The continuous onslaught which has been made on amputations through the foot and lower part of the leg is producing its effect on some surgeons and causing them more often to amputate at the higher point.

The objections alleged against them are:

1. The uncertainty of obtaining useful stumps.
2. That the mechanical appliances are awkward and unsatisfactory.

3. Reamputations are necessary before an artificial limb can be worn.

4. That the disfigurement is so great that it produces a bad effect on the mind and *morale* of the patient.

I had collected ten cases, which it was proposed showing; five were Chopart and five were Pirogoff amputations. Three of the cases were operated on late last summer and last fall. One was a double amputation, one operation being at the seat of election on the leg and the other a Pirogoff; another case was a Chopart, and the third a Pirogoff.

Two cases illustrated the usefulness of the Chopart amputation even when no apparatus was worn. One patient, whom I now show you, had a Chopart amputation performed thirteen years ago, since which time he has worn a shoe made by an ordinary country shoemaker. He is fifty-two years of age, and has never had the slightest trouble with his foot, nor been compelled to lay up a single day on account of it. He is a lumberman by trade, and has been employed continuously at hard laboring work.

The other case—which has disappointed me—is a boy aged seventeen years, on whom I did a Chopart amputation eight months ago. Healing occurred by primary union, and he walked almost immediately, and has since used a common shoe. He has a very slight limp and can walk as fast as he ever did. He is an extremely bad character, and is now what he terms “on the bum,”—that is, he is a professional tramp. What better use could these two cases have had of their limbs if the amputation had been done below the knee?

Three other cases were intended to show the utility of an artificial foot in Chopart amputations. One was a wealthy business-man, whom I was unable to induce to come. He has worn with satisfaction an artificial foot for years. A second is a gate-tender on a railroad, and he has failed to appear. He also wears an apparatus, and is on and off his feet all day and walks very well. The third, the gentleman I now show you, walks, as you see, with almost no limp, and on looking at his feet as he walks it is absolutely impossible to tell which is the affected foot; it is only when his pantaloons are raised sufficiently to see the lacings around the ankle and leg that anything unusual is to be observed. In what way the condition of either of these three cases would be improved by an amputation through the leg, I am utterly unable to see. This last case was one of Dr. John B. Deaver's, my colleague at the German Hospital, and he is wearing an appli-

ance made by D. W. Kolbe & Son, of this city.

I had five cases of Pirogoff amputations, two of whom are present. Two were intended to illustrate the usefulness of the limb when no special apparatus is worn. One is a boy aged sixteen, who is walking around in a small circular leather boot, laced on the stump two or three inches above the ankle, and resting his whole weight on the extremity of the stump on a pad placed in the boot; he has absolutely no pain. The second is a man who is out of work, and is wearing a home-made device until he is able to pay for the apparatus which I here show you. It was made by D. W. Kolbe & Son, and has a socket below for the stump and leather above, which is laced around the calf; it has an ankle-joint and toe-joint. This man has already worn an apparatus like this with perfect satisfaction, and now the one I show is a new one, which has just been completed. A third case I missed owing to not keeping an appointment I had with him. He stopped in at the instrument-maker's, and had his apparatus, similar to the one shown you, put in perfect order, and departed forthwith to Massillon, Ohio, where he joined Coxey's army on its tramp towards Washington. What better evidence could there be of the usefulness both of the operation and the apparatus?

Of the remaining two cases I here show, the first was done by Dr. Deaver at the German Hospital about two years ago. He is a watchman in a large station. He wears an apparatus, and walks, as you see, with a slight limp. He says at times it is not at all noticeable, as it depends on how he feels, and especially as to how the apparatus is laced on. If it is laced firm and straight, then he walks without limping, but if it is loose or slightly twisted, then he limps slightly. Although the amputation was done over two years ago, he has never lost any time, and is positive in his preference of a Pirogoff to an amputation through the leg. He has come in contact with others who have lost their legs by an amputation below the knee, and he thinks they have more pain and discomfort and loss of time than he has had. He patrols a building over a hundred yards long (one square), going completely over it every hour.

The last case is one of double amputation for railroad crush, which I performed last September at the German Hospital. One leg is amputated below the knee and the other is a Pirogoff amputation. He has been wearing the legs only one month, and has not yet gotten thoroughly used to them, and therefore uses a

cane. As is seen, he walks well for one in his condition, and on looking at the feet there is absolutely no visible difference between them. One apparatus looks just as well as the other. On asking him which limb he prefers, he says the one on which the Pirogoff amputation through the foot was performed. The reason is that he feels more secure on it and has greater control over it than over the other. It also feels better, because there is no lacing around the thigh to constrict and chafe him. When standing on his leg amputation, he has to be careful to keep it stiff, or he is apt to lose his balance, while with his foot amputation there is no such tendency. The reason of this is easily seen when we consider the point of support in the former case is eighteen or more inches from the ground, while in the Pirogoff it is only two or three. This case I certainly think is a fair test of the value of the two procedures. The patient is a man of two hundred and twenty pounds weight, and has had experience with both methods, and you have heard him state his preference for the Pirogoff or foot amputation.

It is not claimed that these few cases will settle the question as to which position it is more desirable to amputate, but a constant following of hospital surgical practice for the past fifteen years has failed to convince me that there is any reason sufficient to justify a resort to amputation at the seat of election below the knee when there is sufficient tissue left to perform a proper Chopart or Pirogoff amputation, and this whether, as in two of the cases shown, the patients are in the humbler walks of life, or whether, as in the other two, they are in more affluent circumstances.

Dr. McCurdy, of Dennison, Ohio, has recently stated that he has excellent results from Syme's amputation, and prefers it to the Pirogoff. Of this I have as yet formed no opinion, but I know I can get good results from the Pirogoff, both as regards the use of the limb and as regards cosmetic effects. In performing it, however, as much of the lower ends of the leg bones and as much of the calcaneum as possible should be removed, so that the limb will be shortened enough to enable the instrument-maker to make use of a cylindrical joint beneath the stump and prevent the tension on the tendo Achillis from drawing the fragment attached to it out of place before it has properly united to the tibia. Even if, as Truax asserts, the percentage of those unable to wear artificial appliances in amputations of the leg and foot is as four to fourteen, I still think that the ten per cent. difference does not justify a resort to the higher amputation. When in amputations an

end-bearing stump can be secured, as in these cases, then I believe it ought to be chosen, because, if it be desired, the support derived from lacing the limb above can still be used and the weight shifted from one place to the other at the will of the patient. Satisfactory appliances for these amputations can be secured, which do aid in walking and in rendering the deformity less noticeable.

255 SOUTH SIXTEENTH STREET.

### AMPUTATIONS AND MECHANICAL RESTORATIONS.

BY EDWIN OSBORNE, M.D., PHILADELPHIA, PA.

THE interests of surgery and of the appliances that promote the success of its operations, in the artificial restoration of the lost parts of the human body, are so entirely identical that a few words on the requirements of the latter seem particularly appropriate in a journal of this kind.

The inquiry is often made as to the best point of amputation for the perfect adaptation of the artificial leg.

The choice is not always in the surgeon's hands. In olden times it was customary to amputate, when the injury was below the knee, at the upper third of the leg, with the view of flexing the knee-joint and resting the weight of the body on the knee on the then generally used peg leg. If the injury was at or near the knee, then, when possible, at the lower third of the femur, as giving the best stump or one most easily fitted to the conical socket which would support the necessary pressure on the walls of the stump in walking. In these days, however, the peg leg is rarely seen, and the mutilation is not so palpably advertised. With the advances in the art of constructing artificial legs, new ideas in surgery prevail.

The writer's experience of over forty years in the adaptation of artificial legs to thousands of amputations of every conceivable kind warrants him in thinking that his views may be of interest to the surgeon who, in the exercise of his great calling, has the future comfort of his patient in mind as well as his present relief.

It is certainly safe to say that one cannot have too much of the natural leg. It is the lever that controls the artificial part, and the longer the lever the better the walking results.

Very long stumps are much more difficult to treat, but in competent hands the mechanism can always be skilfully adapted to the amputation. The welfare of the patient is the first

consideration, rather than the convenience of the leg-maker. In the application of the artificial leg the weight of the body must be supported about the amputated leg, consequently anything that facilitates its comfortable adaptation is a great boon to the patient. In all amputations an abundant flap is a great help, for the reason that in taking the pressure about the stump there is more or less tension of the flesh over the end, and if the flap is meagre irritation is likely to follow. It has been the writer's practice for many years, in all cases when practicable, to support some weight on the end of the stump. In many cases, upon a suitable rest, a very considerable pressure can be borne with positive comfort. It relieves the side pressure and the wedging sensation of the support in the tapering socket.

Any amputation that admits of what may be called a natural base of support possesses great advantages. The Chopart operation, where alone the heel is retained, gives a perfect support. The treatment is difficult because of the extreme length, but by practically lengthening the sound leg by means of a higher heel on the shoe, a good result is attainable. The Pirogoff also admits of a perfect support and has this important advantage, it shortens the leg considerably, thus giving ample room for the foot and its mechanism. The Syme operation gives equal advantages.

When necessary to amputate above the ankle, save all that can be saved; for although a very long stump is more difficult of fitting, still, the benefits counterbalance the difficulties. In amputations below the knee it is desirable to have the fibula somewhat shorter than the tibia; it makes a rounder end to the stump, and one very much less sensitive to pressure.

A stump of less than two and a half or three inches in length, reckoning from the lower edge of the patella, is rather too short for the comfortable use of the natural knee, but it can be flexed and the weight borne on the knee, making the knee-bearing leg the most comfortable of all the artificial legs.

Save the knee-joint always when possible, for no matter how short the stump may be flexed, it gives the best possible support and the longest thigh leverage for the control of the artificial knee-joint and leg. When the knee cannot be saved, then the amputation through the joint is the next best.

This amputation has not generally met with much favor from leg-makers, because it requires the highest skill in its treatment. When it is simply disarticulated, covered with a meagre flap, with condyles prominent and patella

slipped a couple of inches from the end, it is about the most trying case one can encounter. But if a considerable portion of the condyles is removed and the patella made to adhere to the end, rounding the stump and protecting the remaining condyles, then, with a good flap, it is an operation of great merit. It gives an excellent base of support, and, though still difficult, can be admirably treated. Above this point, of course, save everything possible.

#### THE USE OF STRYCHNINE IN SNAKE-BITE.

BY DR. MACHER, YARKANDANDAH, VICTORIA,  
TRANSLATED BY  
H. H. BEHR, M.D., BERKELEY, CAL.

BY the request of Baron von Müller, I have the pleasure to communicate to you a complete exposition of my theory and treatment of poisonous snake-bites. From the beginning our mutual friend recognized the importance of my investigations in this matter, and endorsed my statements when they were ignored by other scientists. He also secured for me the honor of the discovery when afterwards the results of my method became generally known. As an introduction, I say a few words about the history of my discovery.

I have now been thirty-five years in Australia, and snakes always had for me a peculiar kind of interest, because, in the very beginning of my medical career in Australia, I almost succumbed to the bite of a tiger-snake (*Hoplocephalus curtus*). As a natural consequence of this accident, I read up the literature on this subject, but derived from this material so little satisfaction that I made up my mind to restrict myself entirely to my own experiences. I had ample opportunities to do so. I like the free life in the "bush" and am a passionate hunter. So I came in frequent contact with my interesting friends, and witnessed the effects of their insidious weapon on men as well as on most domesticated animals.

I soon observed that most of the symptoms could be reduced to functional disturbances of the nervous centres, but for many years I pondered over the question, Are these disturbances direct and primary, or are they produced by decomposition of the blood, occurring at the same time? My own sensations, especially the development of these sensations immediately after the bite, caused me to consider the disturbances of the nervous system to be primary. There was less difficulty in settling the question, Does the paralytic effect of the

poison extend contemporaneously to motory and sensory nerve-cells? My observations lead me to consider the motory cells to be first affected and after them the sensory cells. Some of my hunting-dogs which were bitten on different occasions still showed sensations in the hind legs when they would no longer respond. In the same way, patients of mine who had been bitten without being conscious of it, noticed their state only when they were not able to walk. This symptom had been the first in my own case also; so it was not difficult for me to localize the effects of the poison primarily in the anterior column of the spinal marrow. It was clear, too, that the symptoms, ascending from that point, spread over the entire motory sphere and reached the gray substance of the cortex cerebri. A careful analysis of the symptoms, which with us in all dangerous cases culminate in coma and loss of sensation, supported this theory. The weak action of the heart and the diminution of blood-pressure, fainting, præcordial anxiety, etc., indicated at the same time debility of the vaso-motor centres.

But now, what caused the swelling, extravasations, sloughing in the bitten part, the destruction of the blood-corpuscles, and the dark, not coagulable, quality of the blood?

If my theory were correct, it had to explain these symptoms also.

Unfortunately, science knows little about the consequence of a paralysis of the vaso-motors. At the same time the circumstance escaped my memory during these studies that there exist diminutive ganglia at the ends of vaso-motoric nerves, which evidently regulate the circulation in the capillary system.

These doubts brought it about that years passed by before I ventured to publish my theory. The phantom of blood-poisoning always appeared before my eyes whenever I seriously thought to give my theory to the public or prove it by practical application.

If my theory were correct, strychnine, beyond doubt, was the physiological antidote.

At length, in 1887, I was compelled, in an apparently hopeless case of poisonous snake-bite, to try it. From a long and painful experience I knew my perfect helplessness with regard to the usual antidotes,—ammonium, permanganate of potassium, and alcohol. My patient, a boy of fifteen, was cold, without pulse, and comatose. He had to die at any rate. I therefore resolved upon a daring and energetic application of the theoretical antidote, as I reasoned that it finally amounted to the same thing if the boy died by strychnine

or by snake-poison. There was *periculum in mora*, and so I injected subcutaneously in a short space of time as much as  $\frac{1}{3}$  grain. The result was a brilliant triumph of science, to witness which it was worth while to have lived.

The pulse returned, the face lost its deadly pallor, the patient, before motionless, began to move and to sigh. Another injection of  $\frac{1}{4}$  grain, and he threw himself about as in sleep.

Then I seized him by both shoulders, and, shaking him violently, I called him by name. He opened his eyes, rubbed them like one being awakened from heavy sleep, and looked with astonishment at the persons present. He was in his perfect senses, and in less than an hour he sat at my table eating and drinking, as if nothing had happened.

So the mystery of snake-poison was solved and the correctness of my theory entirely proved.

I was perfectly happy, and kept the boy for several hours under my observation, because the pallor did not yield entirely and the reaction of the pupils of his eyes was but tardy. I administered a full dose of alcohol, but without apparent effect. I did not risk to go beyond  $\frac{1}{3}$  grain of the antidote, notwithstanding the absence of the slightest twitching of the muscles. His state of health did not change, and so I yielded finally to his entreaties to let him go home. Nevertheless, I gave positive instructions to his mother not to allow him to fall asleep, and to call me immediately as soon as any change in his state should take place. But the mother, an ignorant Irishwoman, unfortunately allowed herself to fall asleep; the boy, too, fell asleep, and during his sleep was seized with coma. When the mother discovered it in the morning, she sent for me immediately; but this time the boy died before my arrival. Later experiences have demonstrated that a single injection would have been sufficient to neutralize the remaining power of the poison and would have saved the boy. Since then I made it my rule to continue the injections until the development of slight muscular twitchings; but even then I do not allow the patient to sleep during the first night, and I am now perfectly master of the poison. The poison frequently causes récidives in violent cases, which always have to be conquered by strychnine. The quantity needed for this purpose need not be considered, because the antagonism of the two poisons is so perfect that the specific symptoms of strychnine do not develop before the lethargy and paralysis of the nerve-cells and the influence of snake-poison have been perfectly conquered. In a few cases

I have witnessed tetanic spasms, but they passed quickly, without doing any harm.

This treatment is so simple that it has been successfully administered by intelligent people who were without any medical education.

In bad cases we inject 16 minims of the liquor strychn. (P. B.), and if the patient, after the injection, does not visibly improve, we repeat the same injection after fifteen minutes; then we continue with injections of 8 minims about every fifteen minutes until all the symptoms have disappeared, or until the strychnine begins to develop its physiological effects.

There are many cases when even smaller doses of the antidote have proved to be efficient. In the worst cases  $\frac{1}{4}$  to  $\frac{1}{2}$  grain have been necessary.

At present no sensible medical man doubts any longer the correctness of my method, and public opinion is so outspoken in my favor that a fatal case of snake-bite treated by any other method probably would have as a consequence the trial and punishment of the implicated medical man. There is no doubt that the value of the discovery will be recognized in other parts of the world as well, because snake-poison everywhere attacks the same organ, however different the symptoms may appear at first sight. Paresis and paralysis of the motoric centres is always evident, the only difference being a certain predilection for certain spheres,—viz., the poison of the cobra (*naja*) having a predilection for the respiratory centres, the glosso-pharyngeus, etc.; the poison of the viper (*Vipera Russelii*) for the vaso-motoric centres, etc.

Fayrer, Richards, Mitchell, and others pretend that the poison of the viperinæ is a pure blood-poison, and essentially different from the poison of the elapidæ; but this theory has been fundamentally refuted by the fact that poisoning by the deaf adder (*Acanthophis antarcticus*) is as speedily cured by strychnine as the bite of our deadly pseudedis, predonaja, hoplocephalus, etc., without any remaining symptoms of blood-poisoning.

The theory is very simple; but this very simplicity, in contrast with the predominating confusion of ideas, may have been one of the reasons why some of our professors were so slow in adopting my theory.

The great Kobert mentioned it rather unfavorably in *Schmidt's Jahrbücher*, until, finally conquered by undeniable facts, he was compelled to recognize my merit, but he did so with the remark that there was not anything so remarkable in the discovery, the poison of our snakes being analogous to the effects of

chloral, and strychnine being recommended in overdoses of chloral.

The publication in 1887 of my theory was rather disagreeable for Kobert, because he had experimented for many years with the poison of snakes and spiders, and had arrived at the same conclusions which I published. Feo Klistow communicated, in a dissertation written with the co-operation of Kobert, the results of more than two hundred experiments, which proved the correctness of my theory as to the most minute details. It was a happy circumstance that this essay was not published before the year 1888. Both scientists experimented, like me, with strychnine, but committed the error of generalizing from unsuccessful experiments with lower animals. Feo Klistow, at the end of his essay, pronounces the opinion that in the present state of science a physiological antidote against snake-poison could not even be thought of. He had no idea that at the time he was writing those lines such an antidote was discovered and already in common use at the antipodes.

You will find in the manuscript which I send you many authenticated cases to prove to your American countrymen the correctness of this important discovery, so that it will gain ground and benefit a distant country.

The following notes of three cases of snake-bite treated by subcutaneous injections of strychnine, by H. C. Garde, F.R.C.S., surgeon to the Maryborough Hospital, Queensland, are taken from the *Australasian Medical Gazette* of April, 1890:

CASE I.—At about 7 A.M. on January 26, Miss H., aged thirteen years, was bitten on the outer side of the right ankle by a large brown snake. Within a minute or two a small-sized rope was wound around the leg from the ankle to above the calf, and she started on horseback for town, having to come six miles, and, being delayed in crossing the river Mary, in flood state, she did not arrive at the hospital until 9 A.M. She was then in a nervous and exhausted condition, and had some dragging of the lower limbs on trying to walk. The two punctures were plainly visible. Free incisions were made across them, and the foot placed in warm water; the parts, being congested, bled freely; pressure converging towards the wound was made to increase the flow. Next, 15 minims of the liq. strychninæ (P. B.) were injected into the subcutaneous tissues of the thigh, and five minutes afterwards the ligature was removed. As she looked like fainting, an ounce of whiskey in a little cold water was given. Ten minutes later 10 more drops of liq. strychninæ were

injected, and by 1 P.M. she felt well enough to return home.

**CASE II.**—On January 28 a Kanaka, aged about twenty-two years, was brought in from Jindah Plantation. He was bitten by a snake just above the ankle, and a ligature was applied at once just above the punctures and another one about three inches farther up the leg. He was unable to tell what kind of a snake had bitten him, not being able to speak English. With the exception of his not getting any whiskey, similar treatment was adopted, and he got all right in a couple of hours.

**CASE III.**—On February 26, W. O., aged sixteen years, was bitten by a whip-snake on the ankle. He at once tied his belt tightly around the leg above the wound. He was brought into town about an hour afterwards. The symptoms were slight,—indeed, might fairly be ascribed to fright; only one injection of 12 minims of liq. strychniæ was used; wound treated same as other two cases.

*Remarks.*—In all the cases the bites were situated in nearly the same position, and as none of the patients had on boots or socks, the fangs were applied to the skin direct. The brown snake is looked upon by good authorities as being the most poisonous of all the Queensland snakes. Mr. Johnstone, postmaster of this town, who has lived for over twenty years in the northern parts of this colony, and who has had considerable experience with snakes, tells me that he saw twelve people who had been bitten by brown snakes, and, as he expressed it, he "attended the funerals of the lot," while of seven cases of bites by the deaf adder four are alive at present. He had the misfortune to have been bitten himself some six months ago by a brown snake, and was treated by Dr. Bowe, of Gympie, at first with injection of liq. ammonia and afterwards with liq. strychniæ, to the latter of which he ascribes his recovery. I may say that his case was worse than any of the three treated by me, as he became quite insensible and had, in addition, to have artificial respiration carried on for a considerable time. He informs me that the whip-snake is not poisonous; at any rate, Case III. did not exhibit any symptoms that could not be accounted for by fright, so that he probably would have recovered whether or no.

*Strychnine in Snake-Bite* (from the *Australasian Medical Gazette*, April, 1891).—Through the courtesy of Dr. F. N. Manning, medical adviser to the New South Wales government, we have received a first batch of official police reports on cases of snake-bite, collected by direction of the honorable colonial secretary,

from which we have extracted those cases treated with Dr. Müller's remedy, not yet reported elsewhere:

On March 10, 1891, the officer in charge of police at Murrurrundi, reports that a case of snake-bite, partially comatose, was treated by the local chemist, who injected liq. strychniæ hypodermically, and applied acid. carbolic. and liq. ammon. locally. The patient recovered.

On March 19 the officer in charge of police at Glen Innes reports the death of a woman, aged sixty, from snake-bite. *The injection of strychnine was not used*, but, he says, "everything was done to support the failing nervous system and to stimulate the heart by injections of ether, and strength was supported by alcohol, ammonia, etc.; permanganate of potassium was used locally."

On March 12, 1891, the officer in charge of police at Armidale reports that six cases of snake-bite have been treated in that district by the hypodermic injection of strychnine, of which five resulted in cure; the sixth, not having been attended to until four hours after being bitten, died.

On March 22 the officer in charge of police at Inverell reports that two cases of snake-bite were treated by Dr. Vallée, who injected strychnine hypodermically. Both made a good recovery.

We are informed that Dr. Lilie, of Moree, treated two cases of snake-bite successfully by the injection of liq. strychniæ, and Dr. L. S. Holmes, of Lannceston, also treated a case with Dr. Müller's remedy, full reports of which we hope to publish in a future issue of this journal.

The discovery of this important antidote shares the fate of all discoveries. It is at first treated with doubt and contempt, and when the fact cannot any longer be maltreated, the old comedy of the egg of Columbus is created in a new version. It is rather tedious to look at the petty jealousies which hang round every discovery. We prefer to discuss some peculiarities of the antidote and the poison of which it is an antidote, and we now point out certain rules regarding the administration of such a dangerous antidote.

The very complete casuistics contained in the medical periodicals of Australia prove four things.

1. The strychnine acts regularly and promptly.
2. Its action stops entirely after a time.
3. The snake-poison, like the poison of fungi, of fishes, and mussels, develops irregularly.
4. It sometimes remains latent for a consid-

erable time in the system, so that when it has apparently been conquered for several hours, it suddenly may start a new course of symptoms. This tendency to remain latent in the system, which it shares with many ptomaine poisons, is probably the cause of the irregularity and slowness of its development, of which I have heard in Surabaya of a very striking instance in the case of a Dutch captain bitten by a hydrophis while bathing.

I therefore would recommend not to inject the antidote before unmistakable symptoms of the snake-poison are perceptible, as the poison may act so slowly that the patient succumbs to the strychnine before the state which requires and neutralizes its action has developed.

Secondly, to watch the patient even after the disappearance of the last symptoms for another twenty-four hours, in order to be able to combat in time that insidious sudden revival of the snake-poison to which succumbed the first-mentioned patient.

After having established the fact that strychnine is the physiological antidote of snake-poison, there rises naturally the question, Is snake-poison the physiological antidote of strychnine? Theoretically we can answer the question by "yes," but practically we have to consider the great irregularity with regard to time and intensity of the action of snake-poison.

In the administration of strychnine we can measure the dose to a nicety (a few cases of idiosyncrasy, of course, excepted), but snake-poison is unreliable and treacherous in every sense, as to time as well as to intensity. It is not only the state of the snake from which it is taken that must be taken into consideration, it is also the individual to whom it might be administered. There are few agents in which idiosyncrasy plays such a part as in the action of snake-poison. We know a number of mammalia and birds which enjoy a perfect or limited immunity from its deadly action, some species of weasel, the hedgehog, the glandarius, and, to a limited extent, the stork. There may be individuals of our own species who possess an idiosyncrasy that procures for them immunity, and then there is that insidious survival of the symptoms when all danger seems to be over.

Suppose an overdose of strychnine has been treated with snake-poison, is there any certainty that five or ten hours later the fatal action of snake-poison may not begin? There are several other questions arising from this wonderful discovery of Dr. Müller. Other discoveries may spring up, caused by the results of this first investigation, but for the present let us be thankful for the addition to

our knowledge which we owe to this conscientious discoverer.

#### ADDRESS IN OPHTHALMOLOGY: MEDICINAL OCULAR THERAPEUTICS.

DELIVERED AT THE MEETING OF THE MEDICAL SOCIETY OF PENNSYLVANIA, HELD IN PHILADELPHIA, MAY, 1894.

By G. E. DE SCHWEINITZ, A.M., M.D.,

Clinical Professor of Ophthalmology in the Jefferson Medical College;  
Professor of Ophthalmology in the Philadelphia Polyclinic;  
Ophthalmic Surgeon to the Philadelphia Hospital.

THE art of restoring health to disordered eyes naturally divides itself into (a) Optical Therapeutics, (b) Surgical Therapeutics, and (c) Medicinal Therapeutics. To recount the achievements in any of these departments constitutes a task worthy of the best efforts of an address in ophthalmology.

The improvements in the shadow-test, so many of which we owe to our fellow-member, Dr. Jackson, the increased accuracy in keratometry with the new model of the Javal ophthalmometer, and the designation of prisms by their angular deviation, together with the numerous useful modifications in their practical application, often the result of American ingenuity and industry, especially by Risley, Randall, Jackson, and Ziegler, are only a few of the many instances on the purely optical side of ophthalmic practice.

The surgery of the eye is always attractive on account of the nicety of its manipulations and brilliancy of its results. A profitable hour could be spent in reviewing the operations for the extraction of cataract in our day, and contrasting the successes under the simple and combined methods, or in discussing the claims of different varieties of capsulotomy and the relation of discission to ultimate visual acuity after the primary section.

Although a spirit of conservatism has marked the treatment of concomitant strabismus, the actual operative manipulations have improved, not only in so far as tenotomies are concerned, but especially in advancements, and we may instance with satisfaction among the numerous excellent methods now employed by ophthalmic surgeons the single suture operation designed and advocated by Prince, of Springfield, Ill.

It is to be regretted that the same conservative spirit has not possessed those surgeons who would have us believe they are able to correct degrees and fractions of degrees of heterophoria by picking out a few delinquent fibres from the centre of the tendon of an ocular muscle. It may be that the so-called graduated tenotomies will some time find a place among the proper

methods of ophthalmic surgery, but the evidence to-day certainly is that a healthy reaction has set against injudicious snipping of orbital tendons in the hope of curing all manner of complaints related and unrelated to muscular asthenopia.

The last year or two has been signalized by the appearance of many papers advocating various measures for the relief of obstruction in the lachrymo-nasal duct.

The free discussion of this particular branch of ophthalmic practice has resulted in a better understanding of the causes of epiphora and a classification of cases, separating those suited to pure operative interference from those which must be managed by constitutional measures, by intranasal treatment, or by local means, unassociated with the passage of instruments through the lachrymo-nasal passages. Among the ingenious methods for overcoming organic stricture mention should be made of the excellent stricturotome of Dr. Charles Hermon Thomas, of this city, and also of the clever substitution of a diseased lachrymal duct with a canula of decalcified bone, which slowly becomes incorporated with the tissues, as has been practised abroad. Finally, we note the relegation to the rear of the old-fashioned excision of the lachrymal gland for malignant epiphora, and in its place the less merciless extirpation of the palpebral portion of this structure, as particularly advocated in the French schools.

How great has been the advance in the management of trachoma! It is true that from the earliest days all manner of surgical procedures, from the most brutal and unscientific manipulations to the daintiest crushings of the granulations, have been practised, but we are particularly indebted to Knapp, as well as those who have modified his forceps, for an instrument with which, in selected cases and with the least damage to the tissues, the cure of this stubborn disease is materially hastened. Gratage and brossage, more violent methods and smacking somewhat of the older and rougher manipulations, no doubt find indications in graver varieties of chronic trachoma, but they cannot be commended with the same degree of confidence that the operation of expression, so performed as to milk the entire conjunctiva of its pathological contents, has gained for itself.

These are but a few of the topics belonging to the surgery of the eye that might be reviewed to show the progress of the last few years. Lest, however, the work of the third department of the art of healing eyes, to which reference has been made, suffer by contrast

with the more brilliant results of pure optical and surgical measures, I crave your attention for a few moments to some observations on *medical and non-surgical ocular therapeutics*, and, first of all, to certain uses and abuses of mercury.

As long ago as 1866 injections of a solution of common salt beneath the conjunctiva were recommended by Rothmund for the purpose of absorbing corneal opacities, and, in 1889, Secondi employed similarly-placed injections of corrosive sublimate in an attempt to cure keratitis, iritis, and choroiditis. It remained for Darier, however, in 1891, to classify carefully the diseases suited to this method of administering mercury, and it is to him and other French surgeons, particularly Valude and Lagrange, that the free trial of this method has been accomplished during the past two years.

Based on the theory that a drug which is believed to be antagonistic to a morbid process should be introduced into the affected organ, and thus come in contact in a concentrated form with the lesions it is intended to antagonize, solutions of soluble salts of mercury, particularly the bichloride and cyanuret, have been subconjunctivally injected, (1) to check the infective processes, as exemplified by sloughing ulcers; (2) to neutralize a syphilitic disease, particularly when this attacks the uveal tract; and (3) to act as an antiplastic or alterative in non-specific and non-infective conditions,—for example, chronic choroiditis.

Recent ophthalmic journals have been liberally supplied with reports from France, America, Germany, Italy, and Russia, and we are in possession of sufficient data to conclude that these injections administered to proper cases are not harmful, and that they often dissipate with marked rapidity the manifestations of acquired syphilis in the iris and ciliary body. Their power in episcleritis, infective keratitis, and choroiditis is not so marked, while in the diseases of the optic nerve and retina and inherited syphilitic affections, especially interstitial keratitis, their effect is still less noticeable.

Conceding a definite value to these injections, it is yet too soon to say whether they will supersede other methods of administering mercury. With respect to this point ophthalmologists are in somewhat the same position as genito-urinary surgeons are with regard to the hypodermic introduction of this drug in the treatment of general syphilis,—a method which has recently found renewed favor in many quarters. Whether an objection urged against the latter practice, and well described by Orville Horwitz, that the results, although quickly bril-

liant, are not stable and that relapses are more frequent, weighs with equal force against these subconjunctival injections of sublimate, will be decided by a wider experience and a greater lapse of time.

In some respects subconjunctival injections are an outcome of a more audacious therapeutic measure, originally proposed and practised by Abadie in 1890,—namely, intraocular injections of corrosive sublimate,—in the hope of checking sympathetic ophthalmitis. Although occasional successes were reported, it will be remembered that the practice was abandoned in favor of the subconjunctival method, even by Abadie himself, on account of its frequent inefficiency and distinct danger. Recently certain experimental inquiries in this country and in Scotland have recalled attention, not only to the introduction of mercury directly into the vitreous chamber, but to the whole subject of intraocular therapeutics. My own experiments on rabbits seemed to show that the vitreous, choroid, and retina withstand badly intraocular injections of various antiseptic substances, with perhaps the exception of aqua chlorinata, although in one dog a suppurative hyalitis was apparently cured by injections of corrosive sublimate into the vitreous. The conclusion was reached that before accepting this method of medication, even within narrow limits, much additional knowledge was needed in regard to the exact therapeutic relation of these fluids, when introduced into the eye, to a microbic disease, and especially the relation of the chemical composition of the vitreous to that of the fluid injected. More promising results are apparent from Dr. Chasseaud's research\* wrought upon exactly the same lines, and the interest in the matter is evidenced by the fact that at the next meeting of the Ophthalmological Congress in Edinburgh a special session devoted to the study of intraocular injections has been arranged. Perhaps the facts then to be brought forward will justify Mr. Berry's belief that these injections represent a distinct advance in ocular therapeutics.

Irrational routine treatment has often been responsible for grave therapeutic mistakes, and in special practice there is no better example than the abuse of mercury in the treatment of many diseases of the eye. No doubt the excellent article of Dr. Landolt† upon this subject is fresh in the minds of many of you. Perfectly willing to pay tribute to the paramount

importance of mercury in the management of the numerous ocular manifestations of syphilis, he protests (and in this protest he has, I am sure, the support of all rational therapeutists) against the needless exhibition of this drug in incurable affections, or in those indicating at the same time other reasonable and efficacious treatment.

Landolt has divided his cases into three classes, which, somewhat modified, I may thus describe:

1. The uselessness of prolonged mercurial courses in case of old atrophy of the optic nerve,—for example, in ataxia,—even if remotely caused by syphilis. The drug cannot restore nervous life to the wasted fibres; it can depress seriously the nutrition of the patient, when this, of all things, should be built up. Who that has looked at a section of an atrophic optic nerve beneath the microscope and seen the delicate nerve-fibrils replaced with coarse connective tissue, will not appreciate the force of the argument.

2. The uselessness of mercury in certain chronic affections of the inner tissues of the eye,—cases in which, as Dr. Landolt aptly expresses it, the ophthalmoscope reveals "the ruin of the choroid and retina,"—for example, pigmentary degeneration of the retina, atrophic choroido-retinitis, and disseminated choroiditis. What power can mercury have, no matter how administered, in re-establishing functions to elements which have undergone chronic cicatricial change, atrophy, and positive destruction?

3. The doubtful value of mercury in non-syphilitic chronic exudative inflammations of the uveal tract,—e.g., irido-cyclitis and irido-choroiditis. In other words, the exact cause of these conditions—rheumatism, gout, depressed nutrition from wasting disorders, abnormal menstruation, or chronic uterine diseases—must be discovered and remedial agents directed according to the findings.

It should be particularly remarked that all this refers to vigorous use of mercury, pushing the drug to the point of tolerance, or even beyond. No one doubts the efficacy of the drug in proper dose, especially the bichloride and biniodide, as an enricher of the hæmoglobin percentage of the blood, as a tonic pure and simple, as an antiplastic, and as possessing the subtle influence which we call alterative. Within these limitations mercury must always remain a potent agent in our hands, especially in the early stages of these troubles,—for example, when an optic nerve is on the stage of cloudy swelling, slight oedema, or passive hyper-

\* *Journal of Pathology and Bacteriology*, November, 1893.

† *British Medical Journal*, March 26, 1892.

æmia, when, as Dr. Norris well expresses it, the nerve-head "sickly."

We now naturally pass to the treatment of optic nerve atrophy, whether it be primary, secondary, or consecutive. Necessarily this depends upon the original cause, and general measures directed to the removal or modification of this meet the most important indications. But have we any new method to offer, or new drug, with perchance a selective influence upon the optic nerve; anything better than strychnine, as originally recommended by Nagel in 1871?

When Charcot revived suspension in the treatment of locomotor ataxia, ophthalmologists and neurologists naturally began to observe whether with improvement in the general condition there was amelioration of concomitant visual deficiency. Galezowski, studying cases of tabetic optic nerve atrophy with reference to this point, found suspension of no value, and concluded that while it might act favorably in the nervous troubles depending upon the spinal cord, it had no influence on the alterations in the higher nerve-centres and the morbid phenomena which result from them. Eulenberg and Mendel, however, reported benefit in one case, and the matter has been referred to by Darier, Abadie, Desnos, and Bernhardt. Recently Bechtereff and Vorolynski,\* experimenting with suspension in the treatment of various nervous diseases, have noted, among other things, its good effect upon visual acuity, especially in tabes. Although the improvement thus far obtained is meagre in quantity and the outlook extremely dubious, the subject is of sufficient importance to invite a more accurate study than has thus far been accorded to it.

If it be true, as De Wecker recently said, that it is easier to joke about injections, after the manner of the late Brown-Séquard, than to refute their indisputable effect, under certain circumstances, the relation they bear to ocular therapeutics is worthy of at least a moment's consideration. For example, Galtier, using the injections of organic liquids in a case of tabetic atrophy of the optic nerve, obtained improvement of the visual acuity amounting to nearly fifty per cent. Bourgon's† results, however, in cases of intracranial, diabetic, and tabetic atrophy, were absolutely negative. Darier, while willing to ascribe to the Séquardian injections an excellent tonic effect, especially in reduced, debilitated, or neurasthenic

organisms, failed to secure with them noteworthy improvement in optic nerve atrophy, and De Wecker, who introduced the subject for discussion in the French Society of Ophthalmology, although satisfied with the inefficacy of this method of therapeutics in the ocular indications of ataxia, recommends them because they increase the strength of the patient. Altogether the weight of evidence is entirely against them, in so far as a special or specific influence upon optic nerve degenerations is concerned.

Antipyrin has recently claimed the attention of the French observers in the treatment of optic nerve atrophy, having been introduced to the notice of the profession by Valude,‡ who believes the drug, by reason of its peripheric vaso-motor action, may have a favorable influence in certain forms of optic nerve atrophy which arise from a vascular change in the connective interstitial tissue which constitutes the stroma of the optic nerve. His dose is 1 gramme of antipyrin to 2 grammes of distilled water, given subcutaneously. A few observations confirming Valude's views have been recorded by other French reporters,—for example, by Bourgon; but it is difficult to appreciate the mechanism of its action under these circumstances, especially when we consider that the same value which is credited to it might readily be obtained by less objectionable remedies.

The excellent results ascribed by Boé to lactate of zinc in one case of sudden failure of vision without ophthalmoscopic change, when other measures failed, can scarcely have been more than a coincidence; indeed, this is the practical conclusion of the committee which investigated the matter.

In the medicinal treatment of optic nerve atrophy—strychnine, phosphorus and its compounds, nitrate of silver, antipyrin, and the alteratives—the probable value of nitro-glycerin should not be forgotten. We are all familiar with the temporary beneficial effect of nitrite of amyl upon the visual acuity of certain types of toxic amblyopia, and hence glonoin, in graver forms of atrophy, when they have not progressed too far, may assist in bringing nourishment to the fibres by its vaso-motor influence.

It would be unbecoming to leave the subject of atrophy of the optic nerve without at least a reference to the use of electricity in this affection. The most rose-colored reports of the value of this agent in the treatment of atrophy of the optic nerve has been described, Dor, for

\* *Annales d'Oculistique*, March, 1893.

† *Ibid*, November, 1893.

‡ *Ibid*, September, 1893.

example, reporting a notable improvement in forty per cent. of his cases. On the other hand, the great majority of careful observers are inclined to agree with the assertion of Noyes, that electricity "has failed to vindicate its pretensions to any real value, although by its capacity for exciting phosphenes, it fosters the hopes of a credulous incurable."

Recently Dr. Charles Eugene Riggs has called attention to the value of *voltaic alternatives* in atrophy of the optic nerve,—a method which, I understand, has been used by Drs. Faught and L. Webster Fox, of this city. Dr. Riggs believes that the physiological action of the remedy is more energetic with reversal of the polarity of the electrodes than with simple closures.

Before we can establish the status of electricity in the treatment of atrophy of the optic nerve, a proper classification of the types of the affection thus treated must be given by the reporters, and also, if possible, the precise cause of the malady. This deficiency is notable in many of the records and renders them valueless for scientific purposes. Moreover, these cases should not be published, no matter what the method of treatment has been,—strychnine, stretching, suspension, Séquardian injections, voltaic alternatives, antipyrin, the alteratives, or vaso-motor dilators,—without the most exact measurement of vision, direct and indirect, before, during, and after the treatment; neither should they be reported until sufficient time has elapsed to demonstrate that the improvement has been a permanent one.

Before leaving the subject of electricity, it is seasonable to refer to its use in troubles other than those connected with the optic nerve, particularly opacities in the vitreous humor. More than twenty years ago Carnos recommended the continuous galvanic current under these circumstances; and it was Toulon, I think, who recorded twenty-two cures among twenty-four cases thus treated,—an experience that is scarcely credible. Others have failed to secure the slightest improvement with electricity administered for this purpose, although I am aware that some of my colleagues, especially in this city, believe in its efficacy and employ it with satisfaction.

Within the last month Pansier\* contributes a number of observations on the use of the continuous current in the treatment of irido-choroiditis, and reports the disappearance of adhesions and a calming and sedative effect under its influence. The negative pole is applied to

the lids and the positive in the region of the superior cervical ganglion, with a current of five milliampères' strength. There is enough evidence to make it worthy of further trial, and it is desirable that those who have had an abundant experience should record their results.

Time does not permit the review of the many other interesting applications of electricity to ocular lesions, especially in the treatment of muscular asthenopia, paralysis of the orbital muscles, and corneal opacities.

We are prone to apply the best resources of our art to the relief of eye-strain in the widest acceptance of this term, and are ever endeavoring to perfect our methods for neutralizing refractive anomalies, imperfect balance of the external ocular muscles and deficient accommodative power. But it occurs to me we are not equally active, when all this has been accomplished, in subduing the local effects caused by long-continuance of these abnormal conditions. The picture of a hyperæmic nerve-head, imperfectly differentiated from the unduly flannel-red surrounding choroid, itself woolly in appearance and exhibiting faint dark areas in its periphery, indicating interspaces between its larger vessels, together with a streaked and slightly opaque retina, is familiar to all practical ophthalmologists. It is typical of the asthenopic and aching eye. Mydriatics, glasses, and rest do much for such eyes, but why not as well meet evident indications with remedial agents? We would medicinally treat other organs similarly affected, and why not the eye, when we can actually see the lesions, which in most of the other portions of the body can be inferred only from the symptoms? The iodide and bromide of sodium and potassium, iodide of iron, the alteratives generally and various preparations of ergot, naturally suggest themselves, and I suspect that cannabis indica has a distinct sedative influence upon the retina under these circumstances. When we remember that this congested condition of the deeper tissues of the eye may be a forerunner of organic changes, probably of cataract itself, I am persuaded that such therapeutic precautions are of great value, and if ophthalmology was in no other respect a debtor to Dr. Norris and Dr. Risley, their insistence upon the points just enunciated would always be a monument to their credit.

It is just about a decade since Koller's discovery of the anæsthetic properties of cocaine conferred upon ophthalmology an inestimable service. Since then, from time to time, other substances have come to the front, presenting their claims as local anæsthetics. Thus, we

\* *Annales d'Oculistique*, April, 1894.

have seen ouabaine, erythrophleine, lewinin, helleborein, and strophanthin struggle for recognition, and more or less quickly drop from the list of drugs useful in this respect. Often of pharmacological interest, the amount of irritation which they produce renders their practical application valueless. Whether the same fate awaits the new coca base, tropacocaine, called by Chadbourne, to whom we are indebted for a very interesting research as to its properties, tropsin, remains to be seen. Schweigger, it will be remembered, after several months' experience with this drug, reported favorably,—an experience that has been confirmed by his assistant, Dr. Silex.

Certain disadvantages connected with the use of cocaine are well-known and always avoided by careful operators, especially its power to wrinkle the corneal epithelium and to render this membrane more susceptible to the disturbing action of vigorous germicides, particularly bichloride of mercury. Recently, Mellinger, to whom we owe much for his excellent researches on sublimate opacities in the cornea, called attention to another hurtful action of cocaine,—namely, that it hinders, after section of the cornea, the development of a primary lamellar wound closure, and prevents the formation of a "coagulation support" in the parenchymatous portion of the corneal incision. These researches probably explain some cases of delayed union after cataract section and indicate the necessity of using cocaine in quantity only sufficient to anæsthetize the cornea.

Our list of mydriatics has been enriched within the past year by scopolamine, for the introduction of which we are especially indebted to Raehlmann. This drug, it will be remembered, is an atropoid alkaloid, from the roots of the *Scopolia atropoides*. Certain advantages have been claimed for it: that in smaller dose it is more active and also more sedative than atropine; that the duration of the mydriasis is shorter; that, if properly used, toxic symptoms do not occur; and, finally, that it has no unfavorable action upon intraocular pressure, even if there be pathological increase of tension.\* Raehlmann's communication has been followed by a number of reports abroad and by a few in this country, especially those of Derby in Boston and Pooley in New York, the latter observer being unwilling to commit himself to its superiority over other mydriatics. Sufficient evidence, however, has accumulated that it is a very efficient mydriatic and

cycloplegic agent, and I have no doubt that its exact status will be found when observations, which I understand are being made at present by Dr. Oliver, shall have been published.

When pyoktanin was first introduced by Stilling it threatened to make an impression on ocular therapeutics as intense as its own violent color, but gradually failure on the part of many observers to confirm the results reported by its introducer caused it to fall into disuse, although every now and then some stanch adherent of the drug comes forward and once more flaunts its claims. Perhaps, as Cordonnier has stated, much of the disappointment has been due to failure to obtain real pyoktanin, many of the violet dyes found in commerce being totally inadequate. Personally, I confess a lingering fondness for the drug in the treatment of at least one affection,—namely, purulent disease of the lachrymal passages,—although in all other respects it has failed me. It is mentioned now because it has recently been advocated, and very strongly, as an antiseptic and curative of great power in that dreadful disease, diphtheria of the conjunctiva. Sourdille, for example, uses a salve of methyl-blue (1 to 1000), because Janicke has demonstrated that Loeffler's bacillus does not grow in bouillon containing methyl-blue, even in very minute proportions. If this observation is correct, it is a very important one, and should be confirmed or refuted. The difficulty of judging of its value resides in the fact that it has been employed in connection with other remedies,—alkaline solutions and stronger antiseptics.

Time does not permit a review of the advances in the ocular applications of the antiseptics, nor, indeed, is the subject strictly pertinent to the present address. We have learned, however, from abundant experimental research, that complete sterilization of the conjunctival cul-de-sac and the ciliary margins is impossible, but that proper cleansing lessens the number and the vitality of the micro-organisms, and hence should never be omitted. Proper cleansing, however, does not mean the perfunctory introduction of strong solutions of germicides, especially sublimate, which, improperly applied, are without definite value, and are prejudicial to the corneal nutrition.

Considerable work has been done to establish the value of certain antiseptics compared with bichloride of mercury,—for example, cyanuret of mercury, so strongly urged by Chibret, trichloride of iodine, advocated by Pflueger, biniodide of mercury, endorsed by Panas and by Fenton of this city, and the recently-

\* The experiments of Lqbassow do not confirm this statement.

introduced formaldehyde, which, under special circumstances, Valude has eulogized as a substance of singular power, a recommendation which meets with confirmation in the research of Chas. Slater and S. Rideal,\* just published. Whether the tricresol, apparently destined to assume a front rank among antiseptic substances useful in general surgery, will prove of equal value to ophthalmologists, future experience will determine.

Although almost every germicide and antiseptic solution has been employed in that much-dreaded disease, ophthalmia neonatorum, nothing novel or distinctive has been added to the long list of remedies, unless, perchance, we except the revival of an old remedy,—namely, *copious irrigations* with a solution of permanganate of potassium. This drug, it will be remembered, has reached a prominent place among the remedies now employed by general surgeons in the treatment of urethral gonorrhoea, and there are indications that it should hold a place high in our esteem as an irrigating agent in the treatment of this disease.

While I do not decry the value of bichloride of mercury, properly used, in this affection, I am persuaded that it has very often been the means of seriously impairing the nutrition of the cornea on the one hand, and, on the other, has too frequently lulled the surgeon into a sense of false security, simply because he has introduced within the conjunctival cul-de-sac the solution of a drug which is credited with remarkable germicidal properties, properties which, however, are not exercised under these circumstances.

The serious nature of purulent conjunctivitis in new-born children is recognized by every educated physician, and it was perhaps no exaggeration when Rivière, of Bordeaux, declared that it alone was responsible for nearly one-third of the cases of blindness, and had placed in the care of Europe well-nigh one hundred thousand victims. We know that in our own country more than thirty-two per cent. of the blind owe their affliction to ophthalmia neonatorum, and therefore the measures to prevent it rank in importance with those employed against small-pox and tuberculosis, and demand the assiduous practice of the means which experience has taught to be effective. What these means are it is needless to detail to this audience, but I may be permitted to urge upon each physician here the necessity of his personal influence to assist in securing legislative regulations for the prevention of this appalling cause

of blindness. The matter, as you know, is in the hands of a committee of the American Medical Association, and under the guidance of so able a chairman as Dr. Lucien Howe, of Buffalo. Laws of this character have been passed in New York, Maine, Rhode Island, Minnesota, Ohio, and Maryland, and it is the sacred duty of each one of us to see that similar good legislation shall be enacted in the great State of Pennsylvania.

While, to quote from an editorial in the *Philadelphia Polyclinic*, "It is doubtless too much to claim that all cases of blindness from ophthalmia neonatorum are preventable, ophthalmic surgeons know that it would be very rare if reasonable care was exercised and efficient treatment always promptly inaugurated." When we remember that carefully-compiled statistics demonstrate that over seventy per cent. of all who become blind during the first year of life are rendered sightless by purulent ophthalmia, and that the victims of this disease represent a vast army of thousands upon thousands of human beings, there is a crying need for every measure properly conceived and properly carried out, medicinal and legislative, which shall prevent the disastrous results of this affection. He who takes a hand in this work engages, as Cohn has well said, in a labor worthy of the noblest.

#### A PRESCRIPTION FOR CHRONIC DIARRHŒA.

The *Journal de Médecine de Paris* for May 6, 1894, recommends the following:

R Salicin,  $\text{gii}$ ;

Syrup, a sufficient quantity.

Make into twenty pills, and give 1 pill every four hours.

#### THE TINCTURE OF ACONITE FOR TETANUS.

According to the *Journal de Médecine de Paris* for May 6, 1894, WEDEMAN has obtained excellent results from the use of this drug in tetanus, using the tincture in the dose of 5 drops every two hours and afterwards every four hours, or administering the following prescription:

R Chloral hydrate, gr. xxx;  
Bromide of potassium,  $\text{3i}$ ;  
Tincture of opium,  $\text{3ss}$ ;  
Tincture of aconite,  $\text{3i}$ ;  
Water,  $\text{3iii}$ .

Teaspoonful doses of this mixture may be given every hour.

\* *Lancet*, April 21, 1894.

### THE TREATMENT OF MALIGNANT GROWTHS BY TOXINES.

THE medical profession has during the past year watched with constantly increasing interest the studies of those bacteriologists and clinicians who have from time to time contributed articles upon the value of the treatment of malignant growths by means of injections of pure cultures of the micro-organism of erysipelas or of the toxins derived from this organism and the bacillus prodigiosus. One of the most valuable and interesting of these papers was that of Dr. Coley, of New York, who during the past three years has been carrying out a series of clinical experiments in this line of work. One of his recent reports, it will be remembered, was published in the *American Journal of the Medical Sciences* for May, 1893. As a result of his studies he

reached the conclusion at that time that the injection of toxins produced results almost, if not quite, as good as those obtained by the use of the micro-organism of erysipelas itself, and that their employment was not followed by some of the disadvantageous symptoms and dangers which the micro-organism itself produced. His studies also seemed to prove conclusively that this method of treatment was practically valueless in carcinoma and most useful in cases of sarcoma, particularly where this growth was situated in soft tissues. A still later report has been made by Dr. Coley to the American Surgical Association during the recent Congress in Washington, which is summarized in the *Boston Medical and Surgical Journal* for June 14, 1894, as follows:

Twenty-five cases of sarcoma, eight cases of carcinoma, and two cases of sarcoma or carcinoma were treated with the combined toxins. Including one case treated by the injections of fluid living cultures, there were five cases in which it was reasonable to hope for permanent cure.

The first—sarcoma of the neck and tonsil, twice recurrent—has gone nearly three years without treatment.

A second—sarcoma of the back and groin—is perfectly well and free from recurrence fourteen months after cessation of treatment.

A third—sarcoma of the abdomen and pelvis—is in perfect health one year after leaving the hospital, and the very small portion of the tumor which had not been wholly absorbed has remained dormant.

A fourth—sarcoma of the abdominal wall, which had entirely disappeared under two and a half months' treatment with the toxins—is perfectly well and without recurrence three months after treatment was discontinued.

A fifth—sarcoma of the iliac fossa—is well within one year since beginning of treatment, with the tumor one-third the original size, and the element of malignancy apparently destroyed.

A sixth—recurrent sarcoma of leg and thigh—is still under treatment. The sarcoma of the stump, the size of a hen's egg, has entirely disappeared.

Of the remaining nineteen cases of sarcoma treated, nine others showed marked improvement, while in eight the improvement was very slight and in two no improvement was noted.

Of the eight cases of carcinoma, all but one showed more or less improvement, and in three cases it was very marked.

All of the cases treated were inoperable and hopeless. In all the diagnosis was not only es-

tablished by eminent surgeons, but confirmed by expert pathologists.

No rational explanation of the action of the toxins upon malignant tumors could be offered, except on the assumption that such tumors were of micro-parasitic origin. Admitting this theory, evidence in favor of which is steadily increasing, explanation would be easy,—namely, antagonistic bacterial action.

The conclusions drawn from the cases treated were as follows:

1. The curative action of erysipelas upon malignant tumors is an established fact.

2. This action is much more powerful on sarcoma than carcinoma.

3. This action is chiefly due to the soluble toxins of the erysipelas streptococcus, which toxins may be isolated and used with safety and accuracy.

4. This action is greatly increased by the addition of the toxins of bacillus prodigiosus.

5. The toxins, to be of value, must come from very virulent cultures and must be freshly prepared.

6. The results obtained from the use of the toxins, without danger, are so nearly, if not quite, equal to those obtained from an attack of erysipelas, that inoculation should rarely be resorted to.

This method of treatment has been tried to a very considerable extent in Philadelphia, with results by no means as encouraging as those which have been reported by Dr. Coley. It has been found to produce either no favorable influence, or in other instances the development of a high fever and other symptoms of reaction following the injection have so increased the patient's discomfort and sapped his strength that it has seemed as if the treatment actually hurried the patient towards his end. In two cases of osteo-sarcoma in which the toxins were employed, in which condition, by the bye, Dr. Coley also expresses doubt of their value, no favorable action was discoverable to the writer of this article; in fact, he is convinced that they did harm rather than good. The question as to the real value of this method of treating cases which, under ordinary methods, are absolutely hopeless is still, of course, open to debate, and this article is written not so much with the idea of condemning the method as of reflecting the views which force themselves upon us at this time. The very fact, however, that all such cases have been considered hopeless, and that Dr. Coley has reported recoveries in some instances, should make us very cautious about throwing discredit on a remedial measure which has been successful in any cases.

## THE TREATMENT OF HIGH ARTERIAL PRESSURE.

THE fact that high arterial tension is a condition which requires medicinal interference has become more and more recognized as we have employed the nitrites with constantly increasing frequency. Indeed, it is probable that many physicians of the present day who employ nitro-glycerin or other nitrites as cardiac stimulants in reality get the good results obtained solely through the decrease in the arterial tension, which results in the easier action of the heart. In other words, the improved action of the heart after nitro-glycerin has been given is not due to the fact that it has acted as a cardiac stimulant, but rather that by decreasing the work of the heart that organ is able to perform its functions more satisfactorily. A mistake is frequently made by the careless physician when called to a case in which the heart is evidently failing. Signs of cardiac exhaustion and of dilatation divert his attention from the high arterial pressure, and, as a result, he jumps to the conclusion that the failure of the heart is due to an actual lack of strength in that viscus, when in reality its failure is produced not because it is weaker than normal, but because the arterial tension is so great that even with compensatory hypertrophy it is almost impossible for it to force the blood through the contracted blood-vessels. Too frequently, under these circumstances, the physician attempts, by the administration of digitalis, strophanthus, or other cardiac stimulants, to so increase the power of the heart that it will overcome the tremendous resistance to its normal action. Sometimes, under the effect of this stimulation, temporary improvement does take place, but the rational therapeutics of such a case demands that the pressure shall be taken away, and the heart not only allowed to rest, but also quieted, in some cases, by drugs which, if not direct cardiac depressants, certainly act as sedatives to this organ. It would seem that in many cases of high arterial tension the spasm of the vessels is due more to a condition of hyperexcitability of the vaso-motor system than to any direct pathological change in the blood-vessel wall. For this reason the administration of nervous sedatives is often of advantage, either with or without the use of nitro-glycerin. A prescription such as follows may be employed in some of these cases with advantage, particularly as it aids in relieving the restlessness of the patient, who may rebel against being confined or deprived of exercise:

R Chloral,  $\text{gii}$ ;  
 Bromide of sodium,  $\text{gii}$ ;  
 Syrup of lactucarium,  $\text{f\text{3}i}$ ;  
 Water, q. s. ad  $\text{f\text{3}iii}$  M.

Sig.—A teaspoonful should be taken in a little water every four hours, or not less than three times a day.

In many cases, as is well known, the use of nitro-glycerin, while indicated by the condition of arterial tension, is contraindicated by reason of the headache which it produces in susceptible persons, and in such instances this prescription may also be given with advantage.

*THE MEDICINAL TREATMENT OF SOME  
 OF THE CONSEQUENCES OF  
 EYE-STRAIN.*

THE contest over the value of mydriatics in the correction of errors of refraction continues to be waged in certain quarters, but we believe that the vast majority of careful ophthalmic surgeons are not disposed to reject drugs which abundant experience has proved to be among the most necessary articles in their armamentarium, in spite of the contemptuous references to the "old-fashioned" practice of dilating the pupils before endeavoring to select suitable glasses for the patient, which are occasionally heard.

In a previous issue of the THERAPEUTIC GAZETTE we point out that the cycloplegic action of atropine and other alkaloids of allied physiological properties is only one of several effects which they produce when their solutions are instilled into the conjunctival cul-de-sac under the circumstances just named. Perfectly willing to admit that the terms "congestion of the choroid," "hyperæmia of the nerve-head," "retinal striation," etc., are vague and do not indicate exactly the nature of the process which they attempt to designate, we are none the less persuaded that the retino-choroidal disturbances which are manifest to the ophthalmoscope in eyes long the subjects of strain from uncorrected ametropia do not disappear, and consequently comfort does not ensue, if the refractive error is neutralized without the use of mydriatics. Whether they act by producing perfect physiological rest for a certain number of days (and therefore atropine is the best of all of them), or whether they have some local sedative effect the nature of which we do not quite understand, or whether both of these actions are combined and associated with still others connected with their influence upon local circulatory conditions, is a matter of small importance. The fact remains that these choroidal disturbances disappear when they are

judiciously used, and that comfort and increased ocular health are results otherwise unobtainable.

We are not alone, however, dependent upon the use of mydriatics for securing these results, but may turn with confidence to certain constitutional remedies, prominent among which are the iodides of sodium and potassium, the bromide of potassium and allied salts, ergot, the iodide of iron, mercury in small doses, particularly the bichloride and biniodide, and finally cannabis indica, although perhaps the last-named drug has no selective influence upon the coats of the eye itself, but exercises beneficial influence in a more general way. No one who has watched the steady improvement in the color of a congested nerve-head, the disappearance of the so-called lozenge-like clouds in the periphery of the choroid, so well and so often described by Dr. Risley, and even fine opacities in the vitreous under such lines of treatment, can possibly doubt the efficacy of these drugs. The effort of all treatment is to restore the eye to the highest state of health, and this state cannot be reached so long as the lesions described exist.

Material aid in this respect, after the effect of the mydriatic has subsided, may be gained by the use of two local measures,—namely, hot water and a weak solution of the sulphate of eserine or the hydrochlorate of pilocarpine. It is a well-known therapeutic law that the physiological effects of remedies are frequently more accurately obtained when the drugs are given at stated intervals during the twenty-four hours. So it is with these local measures,—for example, if hot douches or hot stoups are used for exactly the same number of minutes at the same hour night and morning, the local sedation is more effectual than that which follows similar applications at irregular intervals.

Insufficiencies of the lateral orbital muscles so evidently need mechanical treatment in the majority of instances, whether this be with prisms, prismatic exercises, or operative interference, that we do not often employ drugs for their relief, unless we make an exception of strychnine, which, for a long time has been utilized on account of its stimulating effect upon the nervous apparatus, and no doubt every one has seen cases in which good results have followed this treatment. Perhaps these results have been due to the general tonic effect of the drug, just as a muscular insufficiency will often improve when the whole system is brought into better condition by any other form of constitutional treatment. There are a few cases, however, in which either strychnine itself, or, better,

as the writer of this note believes, nux vomica, in the form of a good tincture, seems to have a species of selective influence, although it is confessedly difficult to differentiate between its general action and what may be called its local tonic effect. Be this as it may, either full doses of strychnine, or ascending doses of tincture of nux vomica, the latter drug being increased until the patient is taking 50 or 60 drops three times a day, are at times followed by a marked relief from muscular asthenopia, particularly if the interni are insufficient. Necessarily this method of treatment has not always been used to the exclusion of other measures,—glasses, prisms, and exercises; hence its exact therapeutic relation is difficult to determine, but it is always a proper method to try, provided the retina is not in a state of irritability. If it is, the strychnine or nux vomica is apt to increase the aching of the eyeballs, and is contraindicated precisely as it is in the early stages of irritative lesions in the nervous centres. This fact may explain many of the failures to gain relief with these drugs, when the character of the insufficiency would seem to indicate them.

---

*THE DANGERS OF NON-STERILE ALKALOIDAL COLLYRIA IN CORNEAL LESIONS.*

---

**O**PTHALMIC surgeons are accustomed to exercise every precaution to secure sterilization of the collyria which are to be used after a section of the cornea,—for example, in the extraction of cataract, or similar operation necessitating opening of the anterior chamber. In recent times much attention has been directed to this subject, and we are now in possession not only of the best methods of chemical sterilization, but of certain ingenious tubes and flasks, by means of which at the time of the operation the solutions of cocaine, eserine, or atropine may be rapidly rendered perfectly aseptic by means of heat.

Chemical and bacteriological investigations have proved the necessity of such precautions, because, sooner or later, the solutions of the alkaloids used in ophthalmic practice are infested with micro-organisms,—namely, the micrococcus aquatilis, the bacillus liquefaciens, the proteus vulgaris, the micrococcus prodigiosus, the bacillus implexus, and with various fungi, particularly the aspergillus glaucus. Of these organisms, the proteus vulgaris, the micrococcus prodigiosus, and the bacillus implexus, when introduced into the anterior chamber, are

capable of producing a purulent inflammation of the iris, cornea, and deeper coats of the eye.

It is not alone in connection with surgical manipulations, however, that unclean solutions present dangerous features. They are almost certainly the cause of the toxic conjunctivitis (atropine, eserine, and cocaine conjunctivitis), and, probably, as Philippson long ago declared, the direct source of certain ulcers of the cornea, which, at first simple in character, become infected with these impure drops, and pass into a serpentic or sloughing condition. Recently De Wecker has called renewed attention to this danger, and has practically stated that in the vast majority of cases the use of atropine or eserine in the treatment of corneal ulceration is prejudicial to the cure of the case. He has come to rely almost entirely upon mechanical and antiseptic measures; for example, curetting the corneal ulcer while its surface is being sprayed with a boracic-acid solution, and subsequently bandaging the eye with a dry sterile dressing. While such treatment has much to commend it, we cannot, of course, entirely set aside the use of atropine under these circumstances, particularly when the iris is associated in the inflammation and we wish for the mydriatic effect of the drug. We can, however, with very little difficulty, render these alkaloidal solutions sterile when they are used by the surgeon himself or by competent attendants. It becomes a question, however, whether patients, particularly those who frequent dispensaries, should be given atropine and eserine drops for home use. When we remember that within a very few hours after these solutions come from the druggist's shop they are contaminated with fungi and, after careless handling, with positively pathogenic micro-organisms, it is extremely likely that an ordinary simple ulcer of the cornea, or perhaps an abrasion, may be readily infected, and develop into a sloughing lesion. Therefore it seems wise to insist upon the daily attendance of patients thus affected, so that skilled hands may introduce into the conjunctival cul-de-sac clean solutions, when these are needed.

If the patients can be retained within the hospital (which, unfortunately, is frequently impossible), no source of anxiety on this score is created; but it is more than doubtful whether solutions of atropine given to careless attendants, and still more carelessly used in homes far from cleanly, can be of the slightest service in bringing these corneal ulcerations to a favorable termination; and De Wecker's warning may well be considered, even if we are unwilling

to accept his somewhat sweeping assertion in regard to the valuelessness of alkaloidal collyria, under most circumstances, in the treatment of corneal ulcers.

The necessity for sterilizing solutions frequently, even when they are used by properly-accredited attendants in hospital practice, is, perhaps, too frequently overlooked. More than one recent investigation has shown that the solutions, bottles, and pipettes in treatment cases thus employed are thick with contamination. Therefore each dispensary service, where numerous cases of corneal disease require treatment, should be provided with one of the several excellent sterilizing apparatuses now on the market, which may be so readily and so promptly used that this source of contamination is easily removed.

#### THE PRECOCIOUS TREATMENT OF SYPHILIS.

IN accordance with the teaching of the great syphilographer, Fournier, perhaps the general custom the world over is to delay constitutional treatment of syphilis until secondary manifestations—that is, pronounced constitutional involvement—have established the diagnosis beyond peradventure.

Jullien, a specialist of almost as wide experience, strongly advocates a treatment quite the reverse of this. It is worthy of note that thirty years ago, Diday, questioning what might be called the expectant treatment, made a careful study of a series of cases, one set receiving practically no treatment, the other subject to the full influence of mercury as soon as the primary manifestation was unmistakable. He noted as a result that secondary manifestations were retarded about seven days, but that they were by no means prevented. He, moreover, stated that mercury thus administered seemed to lose its efficacy, and that when these delayed secondaries appeared they were more rebellious to treatment than where no drug had been administered.

Jullien, as a result of similar investigation undertaken some twenty years later, arrived at quite contrary results.

On the employment of the drug hypodermically beneficial effects were still more marked, so that secondaries were delayed not merely for days, but for several weeks, and even when they appeared they were less numerous, thus showing that the action of the virus is not only retarded, but attenuated. The question then naturally arose as to whether by a vigorous and prompt treatment not merely attenuation could

be accomplished, but absolute destruction of the specific poison. As a result of experiments in this line, he finally settled upon the hypodermic use of calomel as proving most efficacious. The preparation he uses is as follows:

R Calomel, gramme i;  
Vaseline, grammes x;  
Sig.—Administer in ten injections.

Of course this mixture must be perfectly sterile. The sublimated calomel should be washed with alcohol and dried in hot air. The vaseline should be distilled and the mixture should be made in a vessel which has been sterilized and flamed and kept perfectly aseptic. The skin is prepared as for a surgical operation, and the hypodermic needle and syringe are boiled. The injection is driven deeply into the muscular tissue of the external iliac fossa and the punctured point is dressed with collodion. Provided the kidneys are healthy, and on this point the surgeon should always assure himself before beginning treatment, there is no danger of salivation, of local septic infection, or of any other complication. The calomel lies in the tissues and is slowly absorbed. In experiments upon animals eighteen months after injection, traces of the drug were found at the seat of operation. The very fact of the drug thus becoming stored in the system necessitates most careful watch for its first constitutional symptoms. Those most commonly observed are gingivitis, thoracic oppression, and a tendency towards syncope. When any such symptoms develop, the drug should at once be suspended. Jullien holds that the moment a primary lesion is detected, if it is favorably situated, it should be excised, but whether or not this operation is performed, no time should be lost in starting the calomel treatment. The injections are made in regions approximately near the seat of primary infection. Thus, if the sore is placed upon the breast or the face, the post-scapular regions are selected. As an immediate result the primary lesion cicatrizes rapidly. Often no true ulceration takes place. This in itself is almost diagnostic of the specificity of the lesion. The series of injections is repeated at about fifteen days' interval. In about two or three or four months a few superficial mucous patches and some slight, irregular, scarcely perceptible skin lesions appear. In the first two months an injection of calomel is made every fifteen days in the dose above mentioned. The ordinary man bears 10 centigrammes very well; those in poor health receive from one-half to three-fourths of this dose. After the second month

an injection is given every twenty days, then every twenty-five or thirty days, in accordance with whether the secondary lesions present themselves or not. After six months soluble preparations may be substituted. Jullien states that he has applied these principles to thirty cases, all of which have been most carefully observed, and as a result he announces himself more than ever convinced of the fact that the most successful treatment of syphilis depends upon the vigorous administration of mercury from the onset of the primary symptom, without allowing the loss of precious time while waiting for the positive diagnosis based upon secondaries. Indeed, there is not a disease in which this principle is not generally recognized that the most successful attack is that made in the beginning.

Guyard, while practically agreeing with Jullien in regard to the importance of the early treatment of syphilis, holds that equally favorable results are to be obtained by other means. Thus, he administers sublimate by the mouth in full doses, holding that otherwise no beneficial effects are obtained. Thus, when the protiodide of mercury is given, at least four grains a day should be administered; the sublimate he gives in 1- to 2- to 3-grain doses.

This treatment proposed by Jullien, or, at least, some modification of it, certainly commends itself to the common sense of every careful student of syphilology. Recently there appeared the promise of a new and entirely efficacious method voiced by Pellizzari and based on modern pathology and coming therapeutics. He endeavored as soon as the chancre appeared to immunize the patient by blood-serum taken from patients who had already suffered from secondaries, and who exhibited no lesions. His results, satisfactory as they were, do not compare with those cited by Jullien. Though this method of immunizing is full of promise, it has not brought us anything of practical value, and we still have to fall back upon the specific which has served us so well for many years; that this has a retarding and destroying effect upon syphilitic virus none deny. This being the case, that the early use should retard and render more mild the secondaries seems self-evident. The objection to this lies in the fact that diagnosis from a primary sore alone is impossible. It is impossible, however, only in a very small percentage of cases, but it is probable that the results in large numbers of cases treated would be better were a plan similar to Jullien's followed, though it is undoubtedly true that a certain very small number of cases would be

subject to specific treatment, although they in reality had never acquired syphilis.

---

## Reports on Therapeutic Progress.

---

### *THE DIETETIC TREATMENT OF DIABETES MELLITUS.*

An interesting paper on this topic is that published in the *Medical Chronicle* for May, 1894, by WILLIAMSON.

Many substances have from time to time been employed (gluten bread, bran cakes, almond bread, etc.). The great objection to these breads are: (1) they are mostly exceedingly expensive; (2) they are often very unreliable; (3) they are not tolerated for any length of time by the patient. With a very little trouble a diabetic patient can have a number of diabetic breads and cakes prepared at his own home, and such home-made preparations are more reliable, less expensive, and more palatable than the majority of those so largely advertised by various firms. Ebstein has drawn attention to the value of a substance named, in Germany, aleuronat. This is a vegetable albumin prepared from wheat by a chemist, Dr. Hundhausen. From this substance bread can be baked by the addition of ordinary flour. It is a cheap form of albumin, and can be used as a substitute for ordinary flour in the preparation of soups, sauces, etc. It is a yellowish powder, and contains from eighty to ninety per cent. of albumin in the dry substance.

The following are the directions for the preparation of bread containing about fifty per cent. of albumin in the dry substance. Aleuronat and white flour are mixed in equal quantities:

- Two hundred grammes white flour equals about seven ounces;
- Two hundred grammes aleuronat equals about seven ounces;
- One hundred and twenty-five grammes butter (of the best quality) equals about five ounces;
- One teaspoonful of salt;
- Twenty grammes (400 grains) of baking-powder.

The flour and aleuronat are mixed in a dish warmed to a temperature of about 30° C., and the melted butter and milk (made lukewarm) gradually added, then the salt, and finally the baking-powder (one part of sodium bicarbonate and two parts of cream of tartar). The dough is well mixed, then formed into loaves, and baked at a good heat.

Cakes composed of aleuronat and cocoanut-

powder are very palatable, very cheap, and are particularly free from starch :

Two ounces of the finest desiccated cocoanut-powder;  
Two ounces of aleuronat;  
One egg;  
A little milk.

The egg is beaten up, and the aleuronat and cocoanut-powder added, together with a very small quantity of milk. The mass is stirred together until a dough is formed. This is cut into thin cakes and baked. The addition of milk is not necessary.

Pavy long ago recommended almond cakes as a substitute for bread in diabetes. The sweet almond contains nine per cent. of sugar and dextrine, but by washing the meal with boiling acidified water, the greater part of the sugar is extracted. Almond meal washed in this manner is almost free from carbohydrate. It contains twenty-four per cent. emulsin and fifty-four per cent. fat.

Owing to the large quantity of fat which they contain, these almond cakes are not easy to digest. Another objection is the price. Only wealthy patients can afford them.

Seegen gives the following directions for the preparation of almond cakes :

One hundred and twenty-five grammes (about one-quarter pound) of sweet almonds are ground as fine as possible in a stone mortar. To remove the small quantity of sugar which the almonds contain, the pounded mass is enclosed in a linen bag, and this is soaked for a quarter of an hour in boiling water to which a few drops of acetic acid have been added. The almond meal is then mixed well with three ounces of butter and two eggs. Then the yel-low of three eggs and some salt are added, and the mixture thoroughly well beaten up. The white of three eggs is beaten up into a froth and then mixed with the above. The mass is divided into cakes and baked by a gentle fire.

Saundby gives the following directions for the preparation of almond cakes :

One pound of ground almonds;  
Four eggs;  
Two tablespoonfuls of milk;  
A pinch of salt.

Beat up the eggs and stir in the almond flour; divide in twelve flat tins, and bake in a moderate oven for about forty-five minutes.

A pound and a half of cakes prepared in this manner cost one shilling and six pence.

Saundby also gives directions for the preparation of cocoanut cakes :

Three-quarters of a pound of desiccated cocoanut;  
One-quarter of a pound of ground almonds;  
Six eggs;  
Half a teacup of milk.

Beat up the eggs, and stir in the cocoanut and almond flour; divide into sixteen flat tins, and bake twenty-five minutes in a moderate oven.

Desiccated cocoanut costs four and a half pence per pound, and the cost of one and a half pounds of the above cake is one shilling two pence.

In Iceland and Lapland, Iceland moss (*cetaria*), deprived of its bitter principle, is used as an article of diet. The soluble portion is taken up by boiling water, and the decoction in cooling thickens and deposits a gelatinous mass. This soluble gelatinous substance is known as lichenin.

Saundby has published directions for the preparation of a pudding made from Iceland moss, which is much appreciated by diabetic patients.

For three hours the Iceland moss is soaked in water, then boiled in milk for three-quarters of an hour, strained, and poured into a mould and allowed to get cold. It may be sweetened, if necessary, with glycerin or saccharin.

#### CICATRICAL NARROWING OF THE OESOPHAGUS.

TRETZE (*Deut. Med. Woch.*, 1894, Nos. 16 and 17) discusses the treatment of the narrowing consequent upon swallowing corrosives. He first records a case in a man, aged twenty-six, coming under treatment early. A peri-oesophageal abscess developed, and gastrostomy had to be performed. The stricture was ultimately successfully treated by bougies, and the gastric fistula healed spontaneously. The principle of not passing a bougie for some time in such cases is very generally admitted. Gastrostomy must not be delayed too long. Any question of oesophagotomy can hardly arise here. The diagnosis of abscess cannot be made until pus is spat up. A second stricture was present lower down in this case, and probably another in the neighborhood of the pylorus. In cases of long standing the bougie should be used, but it is not always successful. The lumen of the tube may be eccentric, or a diverticulum may exist above the stricture. In such cases, where fluids pass with difficulty and the nutrition of the patient is clearly suffering, gastrostomy should be done. An example is given of a fatal case in a child, aged one and three-quarters years, where delay precluded the

idea of an operation. Again, in severe cases, where fluids are swallowed with difficulty, and even small bougies pass, yet gastrostomy may be the only means of successful treatment. Hitherto bougies have been the sovereign remedy here. The passing of bougies is not unattended with danger. A case is recorded in a boy, aged sixteen, in whom, twelve days after gastrostomy, a thread was passed with a sound through the whole length of the œsophagus, one end coming out through the nose and the other through the gastric fistula. A drainage-tube was eventually passed through the stricture, and left. Dilatation was effected, and eventually the gastric fistula was allowed to close. In cases where fluids can still be swallowed and yet no bougie can be passed, a shot, with a thread attached to it, may be swallowed (after gastrostomy), and a drainage-tube thus be got through the stricture. If this procedure is not successful, bougies may be passed up the œsophagus through the stomach. A case of a boy, aged one and three-quarters years, is recorded, in which the dilatation of the stricture (opposite the upper limit of the thorax) could not be effected by way of the stomach. Œsophagotomy was performed, and a diverticulum was found above the stricture. A silk thread with a sound was passed through the œsophagus, and a drainage-tube introduced in this way. Bougies were subsequently passed. The œsophagotomy wound closed in four weeks, and the gastric fistula in one year and three-quarters after its formation, the patient being eventually perfectly well. Another case is related in a girl, aged twenty-two, in whom, after gastrostomy, attempts were made for some time to dilate the stricture from below, but a bougie could not be passed from above. Œsophagotomy was performed, a diverticulum found, and a communication made between this latter and the descending part of the curve into which the œsophagus had been thrown. A drainage-tube was got through, and dilatation completed with bougies, the patient eventually recovering. The author draws attention to the value of gastrostomy in these cases in (1) finding out the site of and treating the stricture, and (2) maintaining the nutrition of the patient. For these temporary gastric fistulæ Witzel's method is recommended. The author holds that (1) gastrostomy should be done in severe cases more often than it has been in the past, (2) continuous dilatation with a drainage-tube is more rapid and less dangerous than with bougies, and (3) combined gastrostomy and œsophagotomy may lead to success in some cases.—*British Medical Journal*, May 26, 1894.

#### THE ACTION OF BROMETHYLFORMINE IN THE TREATMENT OF EPILEPSY.

G. BARDET (*Les Nouveaux Remèdes*, April 24, 1894) publishes the experience of Féré, who has studied the action of *bromethylformine*—a derivative of formol—in the treatment of epilepsy. The new medicament, which is supposed to be represented by this formula,  $C_2H_5N_2.C_2H_5Br$ , is well borne by the animal economy. As a sedative, it has been given to children and adult women, in doses of from 30 to 60 grains (2 to 4 grammes), without causing the untoward after-effects frequently produced by the metallic salts. The remedy under consideration appears to have rendered good service in epilepsy, as shown by the results observed in six cases of that disease reported by Féré. It is asserted that the bromethylformine acts as an excellent substitute to the potassium salt, being particularly indicated in those individuals that exhibit idiosyncrasies against the latter medicament. The bromethylformine appears somewhat weaker in its action, but it is advantageous, from the fact that it does not cause the eruptive phenomena produced by the bromide of potassium. It is affirmed also that in those cases in which the cutaneous trouble was present as a consequence of the administration of the potassium salt, the ingestion of bromethylformine effected the disappearance of said eruption. This remedy is recommended in doses of from 3 to  $3\frac{3}{4}$  drachms (12 to 15 grammes) a day.

#### THE THERAPEUTIC USES OF THE GLYCERO-PHOSPHATES.

In a preliminary communication, ALBERT ROBIN (*Gazette Médicale*, April 28, 1894) treats of the uses of the glycerophosphates in clinical medicine, and concludes as follows:

1. The glycerophosphates are powerful therapeutic agents, ameliorating the general nutrition through an action upon the nervous system.
2. They are especially indicated in nervous depression.
3. Hypodermically injected, these remedies produce effects still more pronounced than those of the testicular juice, whose medicinal virtue depends upon the amount of organic phosphorus which it contains. The employment of the glycerophosphates, definite products, and the dose of which can be regulated, is preferable to that of the testicular liquid, an uncertain remedy and susceptible of alteration.
4. The observations so far made point to the

possibility that the subcutaneous injections of the glycero-phosphates can be utilized in the treatment of nervous asthenia (whatever the cause of the trouble), of phosphated albuminurias, of phosphaturias, of Addison's disease, of the various forms of sciatica, and of facial tic douloureux. In locomotor ataxia the results have been uncertain, but they point to a diminution of the lancinating pains occurring in this disease.

#### APPENDICITIS.

PERIER contributes a note upon this subject to the *Journal de Médecine de Paris* for April 22, 1894. In children he directs that the pain shall be relieved by small doses of extract of opium or by small quantities of morphine. For the vomiting he directs that small pieces of ice or frozen champagne should be given, and that a rectal injection shall be used night and morning, composed as follows:

R Borax,  $\text{giii}$ ;  
Boiled water,  $\text{Oii}$ .

One-half of this to be used in each injection.

If, after this has been done for two days, no symptoms of amelioration ensue, surgical measures should be resorted to. The diet should be absolutely a liquid one, with rest in bed, small quantities of pure water or milk given frequently, and everything done to keep the patient in good condition for operative procedures.

#### THE TREATMENT OF URTICARIA.

In the *Journal de Médecine de Paris* for April 22, 1894, is an article upon this disease. The indications which are to be met in its treatment are the removal of the cause and of the symptoms. It is to be remembered that among the causal factors are a large number of vegetable substances and parasites, and that, in addition, fish, shell-fish, and similar articles of food may produce these symptoms. Among the important drugs which produce urticaria are antipyrin, arsenic, copaiba, chloral, salicylic acid, santonin, the iodides, bromides, and turpentine. Often these eruptions can be relieved by external applications, and of course the causative factor in the eruption should be removed. Certain dermatologists regard urticaria as a disorder of vaso-motor innervation, depending upon a diathesis, and have therefore based their treatment as follows: For vaso-motor disorders they administer sulphate of quinine in the dose of 4 grains twice a day, or 10 grains of ergotine divided in morning and

night doses; or, again, 10 to 20 drops of tincture of belladonna during each day; or, again, they substitute for belladonna the sulphate of atropine in the dose of  $\frac{1}{160}$  grain twice a day.

Brocq recommends the employment of ergotine and belladonna and quinine as follows:

R Hydrochlorate of quinine, gr. i;  
Ergotine, gr. i;  
Extract of belladonna, gr. ss;  
Glycerin, q. s.

Make into one pill and administer 8 to 16 pills, giving 2 pills at a time.

For the urticarial diathesis a severe alimentary régime should be instituted. Red meats and similar substances should be avoided and only white meats taken. Heavy rich foods are also to be avoided. Should an arthritic diathesis be present, alkalies, such as bicarbonate of sodium or Vichy water should be used, or one of the mild purgative alkaline waters resorted to.

Should the urticaria be due to dyspepsia with constipation, the following prescription may be given:

R Benzonaphthol,  
Powdered rhubarb,  
Calcined magnesia, of each, gr. v.

Make into one cachet, and administer such a cachet half an hour before each meal.

Should diarrhoea be present, order:

R Betanaphthol,  
Salicylate of bismuth,  
Prepared chalk, of each, gr. v.

To be put into one cachet, which is to be taken after each meal.

Should nervous irritation be sufficient to prevent sleep, some mild hypnotic may be given,—such, for example, as a small dose of opium, or sulphonal in the dose of 8 grains. Should the nervous irritation be very great, as much as 30 grains may be given in a day; or, in other cases, cachets containing as much as 4 grains of chloralose may be given four times a day. Often, too, bromide of potassium, in moderate dose, with extract of valerian is useful. For the local treatment, lotions and powders are chiefly indicated. Baths are also useful. The patient is directed to take a bath of moderate temperature for a quarter of an hour. The bath contains one litre of vinegar, one litre of glycerin, and two drachms of corrosive sublimate. It should be taken in a porcelain or wooden tub. In relation to lotions there is much room for choice. Some recommend ether in the proportion of one-third, others

vinegar one-third, or, again, Cologne-water in the proportion of one-third, or the following prescription may be used as a lotion :

R Corrosive sublimate,  
Chloride of ammonium, of each, gr. ii;  
Aqua lauro cerasi, ℥iiss;  
Distilled water, ℥viii.

Of the powders to be employed after the bath, we may use simple powdered starch, one-fourth of oxide of zinc, one-tenth of salicylate of bismuth, or one-fiftieth part of camphor. Of the salves, those which contain menthol or phenol are of most value, as, for example, the following prescription :

R Vaseline, ℥i;  
Oxide of zinc, gr. xlv to gr. lxxv;  
Menthol or phenol, gr. v.

#### THE ABSORPTION OF IRON.

MACALLUM (*Journ. of Phys.*, April, 1894) finds that inorganic iron is absorbed (in guinea-pigs) by the intestinal mucous membrane. Whatever iron salt was administered, whether the phosphate, chloride, sulphate, or "peptonate," when the dose was not very large, the evidence of its absorption was very plain in the villi of the upper end of the small intestine, but in them only. When the dose was large, the presence of iron in the villi was observed far down the intestine, but the reaction for iron was less distinct the more remote the villus from the pylorus. With very large doses of the phosphate or "peptonate," the villi near the cæcum gave an intense reaction. It is suggested that the reason for this difference is that, when the dose of iron is small, and when consequently the quantity of iron in the chyme is small, it is wholly precipitated by the alkaline, biliary, and pancreatic secretions; as these three fluids do not at once and completely mingle, the iron is not at once precipitated, and consequently absorption goes on in the first few inches of the intestine. The acidity of a larger dose of iron salt may be sufficiently great to destroy the alkalinity of the chyme after admixture with the bile and pancreatic juice, and, when this is the case, the unprecipitated excess of iron salt will go on down the intestine and be absorbed lower down. When the oxide or the reduced metal is given, a certain quantity of the acid of the chyme is taken up in effecting their solution, and therefore in the intestine the alkalinity of the bile and pancreatic juice must go further in the precipitation of the iron. Speaking generally,

the larger the amount of free acid in the chyme the greater must be the quantity of iron absorbed. Sulphides in the contents of the bowel will also precipitate the iron still in solution. On an ordinary diet, therefore, the extent of intestinal mucous membrane which absorbs iron must be, in proportion to that which does not, remarkably small. Macallum, however, thinks it possible that in anæmia there may be a diminution in the amount of the biliary and pancreatic secretions, a condition which, for the reason above stated, would prevent precipitation, and thus favor absorption. His grounds for stating that iron salts are absorbed—a fact which has been denied—are drawn from microscopical examination of the mucous membrane under various conditions. In well-fed guinea-pigs taking iron the intestinal mucous membrane, after treatment with alcohol, assumes, when treated with ammonium sulphide, a more or less dark color, due to the formation of sulphide of iron, which, under the microscope, is seen to be limited to the sub-epithelial portions of the tips of the villi. Here it is deposited in leucocytes which surround the end of the lacteal vessel. When the dose of iron is larger, or, apparently, when the administration is continued for a long time, the iron is present also in the epithelial cells themselves, and passes from them by a process of internal secretion into the plasma of the venules. These venules are the portal radicles, and leucocytes containing iron are found in capillaries of the liver, and the peripheral cells of the lobules contain iron. Similar leucocytes are found in the spleen. Beyond this point the iron was not traced, and the question whether it is ultimately assimilated and fixed as inorganic iron remains unsettled; but the research serves to prove that iron salts have not, as has been asserted, merely a stimulant action on the epithelial cells of the mucous membrane. Any stimulant action they may exert is a concomitant of their absorption. Though some of the subepithelial leucocytes of the villi appear thus to carry part of the absorbed iron into the general circulation, the more important agent in the transference of the inorganic iron from the villi to other parts of the body is the blood plasma.—*British Medical Journal*, May 5, 1894.

#### THE TREATMENT OF CHOREA.

*L'Union Médicale* for May 12, 1894, gives the following :

Intellectual and physical rest, with sulphur-water baths and bitter tonics, such as quinine

and arsenic for mild cases. In other instances which are more severe, great care should be taken as to the hygienic and gymnastic treatment of a patient, and if insomnia is marked, bromide of potassium should be given but not continued for a long time.

A useful prescription in these cases is,—

R Valerianate of zinc,  
Extract of belladonna,  
Subnitrate of bismuth, of each, gr. xv.

To be made into forty pills, 1 or 2 of which should be given three times a day.

If arsenic is indicated, it is well to employ the arsenate of sodium in the dose of  $\frac{1}{16}$  to  $\frac{1}{8}$  grain progressively increased. Sometimes good results follow from spraying the back of the neck with ether or chloride of methyl. If the case is a very grave one, from 15 to 30 grains of antipyrin may be given a day in fractional doses, and chloral resorted to to produce nervous quiet. It is also well if the patient is strong enough to give a cold douche morning and night, followed, after two or three minutes, by active friction to produce reaction. Should the case become exceedingly severe, inhalations of chloroform are used.

#### TREATMENT OF DYSMENORRHEA.

DR. SCHWARZE (*Therapeutische Monatshefte*, May, 1894) discusses, first, dysmenorrhœas associated with pathological ante flexion and with retro flexion of the vaginal uterus, and with different forms of deficient development of the uterus; secondly, all dysmenorrhœas without recognizable anatomical change.

The first group have this in common, that they may all be referred to a deficient muscular development, to flabbiness or delicacy of the walls of the organ. He thinks that in stenoses of the external and internal os, it is the hypoplasia, not the stenosis, which is the chief factor. So, too, with pathological ante flexion and retro flexion, defective development, not change in position, plays the chief rôle.

In the case of girls in the period of development, general treatment of the frequently associated anæmia and chlorosis is to be employed, including internal treatment in addition to baths, and residence in the country or mountains. In obviating the pain during menstruation, rest and antipyrin, phenacetin, antifebrin, exalgin, and salicylate of sodium play a great rôle.

Frequently the pains disappear under this

treatment, and frequently they do not, in spite of the fact that the anæmia is overcome and the patients become blooming. Ergot sometimes succeeds in such cases, but more often fails. Now the treatment becomes more difficult. It is necessary to mitigate the periodical pains with narcotics. So long as this can be done with codeine or cautious doses of opium, or with atropine or belladonna, there is nothing to be said against it. Frequently these are not sufficient; but beware of the use of morphine. It is least likely to induce a habit in those cases in which only the first menstruations are painful.

We possess, however, two agents not sufficiently appreciated. The first of these is the gymnastic, mechanical treatment of the disease, which was introduced by Thure-Brandt. It is applicable to non-inflammatory cases. The movements which Thure-Brandt recommends are (1) percussion of the loins; (2) rolling of the thigh; (3) with the patient in a standing position, the knees are bent and stretched against her apposition; (4) rolling of the feet; (5) separating the knees and leaning backwards. The movements are performed at home, if possible daily, at any rate daily for one week before menstruation. Favorable results follow this treatment. Schwarze asserts that patients who dance or ride horseback some days before menstruation have much less pain, or none at all.

But in well-developed, not anæmic women, who suffer violently from dysmenorrhœa, special gymnastics are not to the purpose. Here, in non-inflammatory cases, viburnum prunifolium gives brilliant results, which are not to be obtained with any other remedy, except morphine. Schwarze gives a teaspoonful of the fluid extract three times daily, beginning from five to seven days before menstruation.

Schwarze is opposed to local massage in the dysmenorrhœa of maidens, but thinks it is a powerful aid in sterile women. The simplest local measure is the introduction of a sound into the uterine cavity shortly before menstruation. In cases in which introduction of a sound gives transient improvement only, cure is not often obtained with bougies. Dilatation is best done several days in succession, a short time before menstruation.

Electricity he always recommends in severe cases before dilatation. The most satisfactory way is with the galvanic current, with the negative pole, an aluminum sound, introduced into the uterus, and the positive pole, in the form of a flat electrode as large as possible, laid upon the abdomen. A current strength of fifty

to one hundred and fifty milliamperes is employed.

In cases which resist all treatment for years, castration is indicated. But it may be that the nervous disturbances have reached so high a degree that separation will not occur. In other cases the dysmenorrhœa is only one manifestation of a neuropathic condition.

Finally, Brunnberg, of Upsala, has treated twenty-four cases of severe dysmenorrhœa with hypnotism, and cured fourteen and improved seven.

#### SERUM TREATMENT OF DIPHTHERIA.

EHRlich, KOSSEL, and WASSERMANN (*Deut. Med. Woch.*, April 19, 1894) relate their experiences in continuation of the researches of Behring in Professor Koch's institute. The serum was obtained from goats artificially made immune; the milk from these animals also contains the protective substances. The immunity was induced by giving them increasing doses of dead diphtheria cultures. The authors adopt the method of ascertaining the amount of antitoxines present by means of neutralization; making use of a virus equivalent to 3 in 1000 grammes body-weight. The immunity-producing unit is such that .1 cubic centimetre suffices to neutralize .8 of the virus. The authors have treated two hundred and twenty unselected cases of diphtheria in children with the curative serum. The injections were never known to be harmful. At first a single injection equivalent to one hundred and thirty to two hundred immunity units was used, but later the dose was repeated in severe cases. Of the two hundred and twenty cases, sixty-seven were tracheotomized, the mortality being 44.9 per cent. Among the remaining one hundred and fifty-three, the mortality was only 23.6 per cent. In six treated on the first day, there was no death, and in sixty-six treated on the second day there were recoveries amounting to ninety-seven per cent., whereas as in twenty-three treated on the fifth day, the percentage of recoveries fell to 56.5 per cent. The steady decrease in the number of recoveries observed here, according to the time when the patient was first treated, is not seen under any method of treatment, whereas it is in keeping with the experimental evidence. In one-half the fatal cases, the disease was so advanced as to make recovery almost out of the question. In the other half, perhaps, several might have been saved if sufficient serum had been at hand to give several doses. Some children showed great improvement in the first two days, but eventually became slowly worse,

and died ten to fourteen days later of nephritis and especially of cardiac failure. With larger doses an effect on the temperature and pulse, critical in character, was mostly observed. Following their experience, the authors hope that the number of cases of nephritis and paralysis may be lessened. They conclude that (1) the serum should be used as soon as possible; (2) in slight cases two hundred units, but in severe as well as tracheotomized cases four hundred units should be given; and (3) the treatment should be repeated on the same or the following day, according to the severity of the symptoms; the total amount given may be five hundred to one thousand or fifteen hundred units. These figures apply only to the serum used by the authors.—*British Medical Journal*, May 5, 1894.

#### PHENACETIN IN RHEUMATISM.

According to the *Journal de Médecine de Paris* for April 29, 1894, useful results are obtained in cases of acute rheumatism by applying phenacetin externally to the painful parts. The following prescription may be used:

R Phenacetin, gr. lxxv;  
 Lanolin, ʒvi;  
 Olive oil, a sufficient quantity.  
 To be rubbed about the inflamed part.

Or,

R Phenacetin, gr. lxxv;  
 Alcohol, Oii.

In this solution dip compresses and apply to the painful parts.

#### TREATMENT OF DIABETES MELLITUS WITH SALICYLATE OF SODIUM.

DR. ADOLF MICHAELIS (*Therapeutische Monatshefte*, May, 1894) refers to others who have reported the use of salicylate of sodium in diabetes, and then reports a case.

The man was fifty-eight years old, of strong constitution, excellent appetite, and good digestion. Diabetes was discovered in 1877, and was possibly due to an injury to the back. Upon a diet that was not strict, which was undertaken only during a year's cure at Carlsbad, the percentage of sugar varied between one and four, the specific gravity from 1020 to 1036. Albumin, acetone or diacetic acid were never recognized. From the middle of September to November 23, 1890, he took daily 8 to 10 grains of salicylic acid for rheumatic disturbances. At the end of that time he developed a series of gastric and cerebral symptoms proved to be due to salicylic-acid poisoning. The urine was free from sugar; specific gravity, 1016. The salicylic acid was stopped, and the sugar

promptly reappeared, and varied, as before, according to diet, between one and four per cent. The patient was not under examination while taking the salicylic acid, so that one cannot say how long sugar had been absent.

#### WALNUT LEAVES IN SCROFULA.

G. P. RÓDIONOFF, of Moscow (*Méditsinskoie Obzrenie*, No 2, 1894), on the ground of extensive observations of five years' duration, recommends the old-fashioned popular treatment of scrofula by a prolonged course of a decoction of walnut leaves (*Folia nucis juglandis*), which should be used both internally and externally in the form of local washes and general baths, made two or three times weekly. Little children should be given half a cupful, older ones a cupful or even a "jugful" of the "tea" every morning and evening. The leaves prove especially beneficial in cases of itching, eruptions, and enlarged glands. In the author's hands the treatment, the duration of which varied from two months to two years, failed only in a few exceptionally refractory cases, and in impatient and unmanageable children who did not take the "tea" in a regular manner.—*British Medical Journal*, April 28, 1894.

#### A DEATH FROM BROMIDE OF ETHYL.

*L'Union Médicale*, May 8, 1894, states that MENDOZA reports a case of death following anæsthesia produced by bromide of ethyl. Ten seconds after the application of the compress to the face the patient's color became cyanotic and the veins turgescient, the eyes were moved convulsively, the pupils were widely dilated. Rhythmic tractions of the tongue and artificial respirations were practised thirty minutes and active flagellations resorted to without effect. The cause of death seemed to be respiratory failure.

#### THE TREATMENT OF NOCTURNAL ENURESIS.

DONALD MACALISTER, in the *Practitioner* for May, 1894, writes of this subject. He points out that patients suffering from this troublesome affection, which has proved rebellious to the ordinary methods of treatment, come not infrequently under the notice of the physician at the age of puberty. During childhood the complaint has been tolerated, and simple means of relief, disciplinary and other, have alone been tried. A little perfunctory medication,

or, it may be, such surgical treatment as circumcision or "cold sounding," is all that has been attempted, and yet the enuresis persists. As the little patient advances in age the disability becomes more urgent; and when the time comes for sending him or her to a boarding-school or away from home, the parents grow increasingly anxious to have the habit broken.

MacAlister in such cases, having first ascertained that no condition requiring surgical interference exists, uses atropine in doses gradually increased to the full limit of tolerance, and in no instance, out of some twenty cases, has he failed to bring about a cure. The following history illustrates the method adopted: A youth of fourteen had passed the examination for admission to a large public school, which he was to join in three months. From early childhood he had been accustomed to "wet the bed" twice or thrice a week. He had been treated from time to time by several practitioners, with ergot, tincture of belladonna in ro-minim doses, Parish's syrup, bromides, cauterization of the urethra with solution of nitrate of silver, blistering of the perineum, and ultimately circumcision. Each new treatment checked the enuresis for a time, but soon it recurred; and when coming under observation first it was as troublesome as ever. The house-master had informed the parents that he could not receive a boarder so affected, and they were in despair lest his infirmity should prevent his admission to the school and so spoil his career. They were eager to try anything in reason for his relief, and consequently carried out the directions given with praiseworthy care. The prescription ran thus:

R Liquoris atropinæ sulphatis, ʒiiss;  
Liquoris strychninæ hydrochloratis, m̄xlvi;  
Syrupi aurantii, ad ʒi.

Sig.—5 drops of the syrup to be taken in a tablespoonful of water at 9 P.M.; to be increased as directed.

The directions were: That no drink should be taken after 6 P.M., that the drops should be taken at 9, that the boy should go to bed after emptying the bladder at 10; that he should be waked to pass water at 12 when the parents retired, and again at 6 A.M. when the servants rose. 5 drops of the syrup were to be taken nightly for three nights, 10 drops for the next three, 15 for the next three, and so on until in the fourth week 30 drops were taken. During this time no "mishap" occurred; there was considerable dilatation of the pupils, and some dryness of the tongue and throat, but no untoward symptom. The dose was continued

at 30 drops for a week, when enuresis again took place. The dose was again increased every three nights by five drops at a time until 50 drops (representing about  $\frac{1}{10}$  grain of sulphate of atropine) were being taken nightly. Accommodation at this time was so affected that the boy could not see to write, though he was perfectly well in other respects. As at this point he had to enter for a two days' written examination, a solution of salicylate of eserine was instilled into the eyes, without stopping the atropine. This enabled him to see sufficiently well to take the examination and to pass with credit. As he and his parents had from previous experience been impressed with the notion that the third week of treatment was a critical one, and that at the end of six weeks a second relapse was to be feared, they were directed to continue increasing the dose up to 60 drops, and to continue this dose for a week. No "mishap," however, occurred, and the dose was then decreased ten drops every three nights, until, after nine weeks of treatment, it was discontinued; the enuresis never returned.

In other cases the writer has used gradually-increasing doses of the tincture of belladonna; but the uncertain strength of this preparation, and the large quantity that has to be taken to obtain its full physiological effect, have caused him to fall back upon sulphate of atropine as more eligible in every respect. In one patient, a girl of seventeen, he pushed the dosage up to 25 minims of the solution nightly, with ultimate success. In no instance have the secondary effects been at all alarming, or, indeed, more than slightly inconvenient. The patients themselves are usually so keenly anxious to be relieved of their infirmity that the inconveniences are cheerfully borne, when it is explained that they will pass off entirely when the medicine is stopped. Cerebral or cardiac disturbances have not been observed.

The secret of success in obstinate cases lies in courageous overdosing. If ordinary means have failed, atropine will not succeed, unless it is pushed to the utmost. The well-known tolerance of the drug by young patients should give the physician confidence in putting the subjects of enuresis under its full influence. The addition of strychnine to the mixture probably diminishes the depressant effect of large doses of atropine, and increases the sensitiveness of the vesical centres to reflexes from the bladder-walls. Some patients have said that, whereas they had been accustomed to wake only to find that the bladder had emptied itself spontaneously, they now were able to get up in time to pass water.

#### A NEW METHOD OF USING COCAINE FOR LOCAL ANÆSTHESIA.

KROGIUS (*Centralbl. f. Chir.*, No. 11, 1894) describes a new method of producing cocaine analgesia, which is based on the fact that when a solution of this agent is injected into the subcutaneous tissue near to a nerve-trunk it causes loss of sensation over a large zone corresponding to the peripheral distribution of this nerve. In order to reach the selected nerve-trunk with certainty, and to apply the cocaine to several of its branches at the same time, the author, in injecting the subcutaneous tissue, passes his needle across the long axis of the limb, and as the needle is thrust along the solution is gradually discharged. An injection made in this way across the root of a finger will, in the course of ten minutes, result in analgesia of the whole digit,—not of the skin only, but also of the tendons, the periosteum, and all the deep structures. If one or two injections be made transversely near the wrist, a considerable extent of the palm of the hand may be thus rendered analgesic. The sensibility of the ulnar side of the hand as far as the roots of the last two fingers may, it is stated, be abolished by injecting a solution of cocaine over the ulnar nerve at the back of the elbow. By injecting over both supraorbital notches, analgesia may be produced in the whole of the middle portion of the forehead. The analgesia caused by this method of using cocaine attains its greatest intensity and extent from five to ten minutes after the injection, and is maintained for a quarter of an hour or even longer. The author injects only a weak (two-per-cent.) solution of cocaine, and keeps the patient recumbent for at least a quarter of an hour after the operation. This method has been practised with success at Helsingfors in two hundred minor operations, such as amputation of the fingers and toes, excision of palmar fascia, and phimosis.—*British Medical Journal*, May 26, 1894.

#### RESECTION OF INGUINAL ARTIFICIAL ANUS.

MR. HERBERT ALLINGHAM showed a patient who had recovered from a previous operation, but all the motions were passing by the inguinal opening, and the spur about the opening was getting more prominent, in spite of an attempt to reduce it daily by pressure with the finger. This being the case, it appeared to him useless to attempt any plastic operation to close the artificial anus. The patient having been anesthetized, a sponge was first put into the artificial anus. The skin around the artifi-

cial anus was then divided, and the peritoneum opened as soon as the mass was entirely freed from the skin around; the anus and gut were next pulled well out of the abdomen. To do this it was necessary to separate some omentum from the gut, it having become adherent to it as a result of the fixing up of the gut to the opening in the belly-wall at the first operation. The sigmoid flexure having a fairly long mesentery, it was easily drawn well out of the belly. The abdominal cavity being well protected by sponges, two drainage-tubes were passed through the mesentery and secured with clip forceps around the gut about three inches above and below the artificial anus. About four inches of the gut with the anal opening in it were then cut away, a piece of the mesentery being also divided. A continuous silk suture was used to bring the mucous membrane of the upper end of the gut to the mucous membrane of the lower end of the divided gut. This suture was passed from one to the other very loosely all around. Then a Mayo Robson's bobbin was inserted between the loose stitches into both ends of the divided gut, and when well inserted the continuous stitch was drawn up tight, so bringing the mucous membrane of both ends of the gut firmly together over the bobbin, the bobbin acting as an excellent frame to keep the ends of the bowel together and also to allow of the careful insertion of Lembert's sutures, uniting the peritoneal surface of the upper to the lower end of the divided gut. A few sutures were then used to unite the cut in the mesentery. The bowel was then washed and returned, the abdominal wound being united with silkworm-gut suture in the usual manner.

It is satisfactory to note that the patient has made a perfect recovery and has left the hospital.—*Medical Press and Circular*, May 16, 1894.

#### THE TREATMENT OF LEAD-POISONING BY MONOSULPHATE OF SODIUM.

The *Journal de Médecine de Paris* for April 29, 1894, points out that PEYRON in 1891 stated that the monosulphate of sodium is an excellent drug to antidote the effects of acute lead-poisoning, for the reason that it aids very extraordinarily in the elimination of the lead from the organism. The experiments carried out by the investigator upon dogs proved this point beyond doubt.

#### MYXEDEMA AND THYROID EXTRACT.

CRARY, of New York, writes of this topic in the *American Journal of the Medical Sciences*

for April, 1894, and concludes that the effects of thyroid administration may be summed up as follows:

Increased metabolism, shown by,—

1. Elevation of temperature.
2. Increased appetite, with more complete absorption of nitrogenous foods.
3. Loss of weight, with nitrogen excreted in excess of that taken in the food.
4. Growth of skeleton in the very young.
5. Marked improvement in body nutrition generally.
6. Increased activity of mucous membranes, skin, and kidneys.

The rheumatic symptoms and the anæmia are not only not relieved, but are most frequently aggravated.

#### THE TREATMENT OF HABITUAL CONSTIPATION IN THE NEW-BORN.

The *Journal de Médecine de Paris* for April 22, 1894, gives the following directions for treating this condition:

Regulate the nursing; see that it is done every two or three hours. If the child is not nourished at the breast it may be necessary to feed it from the bottle, and under these circumstances cow's milk should be chosen which is very rich in cream. A small rectal injection of warm water may be given morning and night at the same hour, and if this is unsuccessful in producing a movement a small suppository of coca butter may be given, or a few drops of glycerin and water injected. It is also useful to use general massage over the abdomen with camphorated oil. A warm bath should be given every day, and the child should get as much fresh air as possible.

In somewhat older children care should be taken that the diet is regulated and that sweets are avoided, while vegetables, such as beans, prunes, and similar substances, are used. Injections or glycerin suppositories may be used once a day. Before each meal a teaspoonful of a syrup composed as follows may be given:

R Syrup of rhubarb,  
Syrup of gentian, of each,  $\mathfrak{z}\text{iv}$ .

Or in the morning a teaspoonful of the following prescription:

R Castor oil,  
Syrup of orange-flowers, of each,  $\mathfrak{z}\text{vi}$ .  
Shake well.

In addition, abdominal massage, baths, and out-door life are very useful.

[The disadvantage of employing either rhu-barb or castor oil is the fact that they both tend to produce constipation after making the bowels act. *Cascara sagrada cordial* would be a much better prescription, in the dose of from 1 to 3 teaspoonfuls.—ED.]

In still older children, in addition to regulating the diet, the child should be taught to eat slowly and masticate its food thoroughly, and in the morning to take a teaspoonful of the following mixture :

R Calcined magnesia,  
Sulphur,  
Cream of tartar, of each, ℥vi.  
Oil of anise, ℥xv.

Recourse may also be had to rectal injections and glycerin suppositories, or the following prescription may be given by rectal injection :

R Infusion of senna leaves, gr. lxxv to gr. cl;  
Water, ℥iv to ℥viii.

Should there evidently be marked atony of the liver, once or twice a week a powder composed of calomel and scammony, of each 4 to 6 grains in a small cachet or in syrup, may be used. In still other cases, before the evening meal, a pilule containing  $\frac{1}{16}$  to  $\frac{1}{8}$  grain of podophyllin may be administered. Where there is insufficient intestinal secretion, citrate of magnesium may be given once a week, or a small wineglassful of some purgative mineral water. Should there be inactivity of the intestine, 8 to 12 drops of the following prescription may be used :

R Tincture of nux vomica, ℥xxx;  
Tincture of belladonna,  
Fluid extract of cascara sagrada, of each, ℥ii.

Hydrotherapy, exercise, massage, and electricity with faradization of the abdominal walls and the use of the continuous electric current are also valuable therapeutic aids. Should there be evidences of intestinal obstruction, with stercoraceous vomiting, with constipation, meteorism, and a cylindrical tumor showing obstruction, the child should have a hot bath, after this copious intestinal irrigation of hot boric-acid solution, to which is added 1 or 2 teaspoonfuls of glycerin, and if the obstruction does not seem to be severe, 2 to 6 drachms of castor oil. A liquid diet, consisting chiefly of milk flavored with coffee, is to be used.

#### COMPOUND TINCTURE OF COAL-TAR.

In the *American Journal of the Medical Sciences* for April, 1894, DUHRING writes a paper on compound tincture of coal-tar.

Summing up the result of his investigations, we may conclude,—

1. That the best tincture of coal-tar is made with the aid of tincture of quillaia.
2. That the strength of the tincture of quillaia should be 1 to 4, with ninety-five per cent. alcohol.
3. That the coal-tar (1 part) should be digested with the tincture of quillaia (6 parts), with frequent agitation, for not less than eight days, and preferably for a longer period, and finally filtered.
4. The resultant product is a brown-black, clear tincture, which, upon the addition of water, forms a cleanly yellowish emulsion, the color and certain other characters varying with the kind of coal-tar employed.
5. The tincture is stimulating and is prescribed usually largely diluted, with from 10 to 60 parts of water, as a wash, and is useful where tar is indicated, as in certain forms of eczema, psoriasis, pruritus, and other inflammatory diseases of the skin. It is often more useful when employed weak than strong.
6. This preparation, which may be designated as "compound tincture of coal-tar," takes the place of several similarly composed proprietary preparations, known as "liquor carbonis detergens" and "coal-tar saponine."

#### PRESCRIPTIONS.

For whooping-cough in an infant :

R Sulphonal, gr. i;  
Creosoti, ℥ii;  
Syrupi tolutani,  
Aque, of each, ℥ii.  
Misce et fiat mistura.

2 teaspoonfuls to be given every two hours.

For amenorrhœa :

R Hydrargyri perchloridi, gr.  $\frac{1}{4}$ ;  
Sodii arseniatis, gr. i;  
Ferri sulphatis exsiccatae, gr. xxx;  
Potassii carbonatis, gr. xv;  
Extracti nucis vomicae, gr. v.  
Misce et divide in pilulas xxx.  
1 pill to be taken before each meal.

For bronchorrhœa :

R Copaiba, ℥iii;  
Spiritus chloroformi, ℥i;  
Mucilaginis acaciae, ℥vii;  
Liquoris potassae, ℥i;  
Aque cinnamomi, q. s. ad ℥viii.  
Misce et fiat mistura.

An eighth part to be taken three times daily.

For bronchitic asthma :

- R Extracti stramonii, gr.  $\frac{1}{8}$ ;  
Potassii iodidi, gr. v;  
Ammonii carbonatis, gr. iv;  
Tincturæ lobeliae ætheræ,  $\mathfrak{M}$  v;  
Aquæ chloroformi, q. s. ad  $\mathfrak{Z}$ ss.  
Misce et fiat mistura.

A tablespoonful every four to six hours.

Paste for eczema :

- R Acidi salicylici,  $\mathfrak{z}$ i;  
Zinci oxidi,  $\mathfrak{z}$ iii;  
Pulveris amyli,  $\mathfrak{z}$ iv;  
Adipis lanæ hydrosi,  $\mathfrak{z}$ i. M.  
Fiat unguentum.  
To be applied daily.

—*Practitioner*, June, 1894.

#### POISONING BY GUAIACOL.

FRIEDENWALD writes in the *Maryland Medical Journal* for May 12, 1894, that the external application of guaiacol for the reduction of febrile conditions has been given a prominent place in recent medical journalism. It is important, therefore, to direct attention to the toxic symptoms in the first fatal case of guaiacol-poisoning.

Professor Oscar Wyss, of Zurich, reports in the *Deutsche Medicinische Wochenschrift* of March 28, 1894, the case of a girl nine years of age, who had been accidentally given 5 cubic centimetres (75 drops) of guaiacol. In a short time she became unconscious; the conjunctivæ became injected, the corneal reflexes diminished, and the pupils no longer reacted to light; there were frequent attempts at vomiting, and the saliva flowed from the mouth in large quantities. The pulse became rapid, the sensibility of the skin much diminished. Finally, the patient began to vomit; the physician detected the odor of guaiacol. The stomach was washed out, but she did not rally. The cyanosis gradually diminished, and instead of it a deadly pallor was observed; the respiration became frequent. Three and a half hours after the guaiacol had been swallowed the patient passed one hundred cubic centimetres of brownish-red urine.

The spleen and liver soon enlarged, and the temperature fell to 35.5° C. (96° F.), and small hemorrhages were observed upon the skin of the arms and legs. The urine contained albumin, blood, and casts, and Ehrlich's carbolic-acid test was positive.

Jaundice soon appeared, the stupor increased, and the patient died on the third day.

The autopsy revealed an acute gastritis and

enteritis, parenchymatous degeneration of the liver, acute hemorrhagic nephritis, parenchymatous degeneration of the heart-muscle, and ecchymoses in the pleura, peritoneum, endocardium, and pericardium; the spleen was much enlarged.

Kobert, in his text-book on "Intoxicationen," points out that after 1-gramme (15 drops) doses of guaiacol slight appearances of poisoning may supervene. These are characterized by a burning feeling in the stomach, nausea, etc. In one case, in which fifteen grammes (3 $\frac{3}{4}$  drachms) were accidentally taken by a patient in the Dorpat Clinic, the stomach was immediately washed out and the patient was rescued. However, unconsciousness set in, the pupils became contracted, the breathing irregular, and the intensely dark appearance of the urine was very noticeable.

#### SODIUM NITRITE AS A THERAPEUTIC AGENT.

In a valuable paper on this subject in the *Practitioner* for May, 1894, SHARP reaches the following conclusions :

Sodium nitrite, being stable, may replace the less stable amyl and ethyl nitrites. It dilates all the arterioles rapidly, and so rapidly relieves the heart. Disagreeable symptoms may be overcome by prescribing it with ammonia water or spirit of chloroform and small doses of morphine. It is most useful in anginal affections and in irregular heart action. To obtain most benefit from its use it should be continued some time after all symptoms have passed off; by this means the heart is able to regain its tone and so to repair itself. The maximum dose is 4 or, at most, 5 grains, and generally 1 or 2 grains are enough. Graves's disease would appear to be aggravated by it. Bronchitis and asthma are not, in Sharp's experience, benefited by its use.

#### PEPSIN LAVEMENTS IN DYSENTERY.

Pepsin has been applied to very many of the diseases of the nosology, yet it remained for DR. SUMMERS, of Waukesha, Wis., to discover that it possesses a most satisfactory therapeutic action in dysentery. He washes out the bowel with a strong solution of pepsin ( $\frac{1}{2}$  ounce to 6 ounces of warm water) every three hours, which act, he declares, "clears off the mucous surface effectually." He next employs a soothing injection, such as laudanum and starch, as hot as can be borne. He declares that after two or three washings and injections the patient experiences great relief, and healthy action is at

once set up, when, if constitutional conditions receive due consideration, rapid healing follows.—*Medical Age*, May 10, 1894.

#### RECTAL ULCERATIONS.

SPECHT has an article on this subject in the *Northwestern Lancet* for May 1, 1894.

In describing the treatment of rectal ulcerations, the author divides them into two classes: first, those which come under the influence of the sphincter area; and, second, those above it in the rectum. The former are generally met with in the form of painful fissures and excoriations, the pain being most pronounced during the passage of the feces over the sore, or some little time after when produced by spasm. In the former variety the patient should come daily to the office for treatment, with, in some cases, a weak solution of silver nitrate, in others a 30- to 60-grain solution, up to even a saturated solution for caustic effect. Sometimes a mixture of equal parts of carbolic acid and tincture of iodine is useful. Most cases are easily cured by this plan of treatment, if the bowels are kept in as liquid a condition as possible, the patient having at least two or three passages a day, thereby causing less irritation of the sore. Another good local treatment in some of these cases is to lay a pledget of absorbent cotton, dusted with iodoform, in the bottom of the sore, and change it daily.

When this fails, and we have a persistent, irritable ulcer, division of the sphincter is the next procedure we would think of, and, as Kelsey says in regard to this operation, we do not need to cut entirely through the sphincter; still, we should go deep enough to produce a certain amount of laxity about the ulcer.

And now we come to the treatment of ulcers farther up the rectum, the ones the most tedious and difficult to heal.

Before attempting to treat this class of cases the writer obtains the co-operation of the patient by consenting to absolute rest in bed and in the horizontal position; no sitting up in bed or about the room or on a lounge, but in bed, with the hips lower than the shoulders, if possible.

To show the value of this position in bed in the cure of the latter class of rectal ulcerations, an ulcer of the leg is a fair example, where the veins are in a varicose condition, as they are apt to be likewise in the rectum. In such an ulcer on a leg in that condition we all know how difficult it is to heal it unless we bandage the limb or place it in a horizontal position; washes, powders, and ointments are without

avail unless we do this. So it is with the rectum. Although we cannot bandage it, we can do the better way, and that is to place the rectum, like the leg, in a horizontal position. We thus relieve the enlargement of the veins, and thereby allow a quicker and more abundant supply of the life-giving current of arterial blood; still more, the current is aided by giving 2 or 3 grains of opium a day internally. Opium is a good capillary stimulant, and thereby a great factor in the healing of sores. We can assist still more by giving a highly nutritious diet, mostly liquid, however, with the exception, possibly, of bread and crackers. Add to this the food tonics, cod-liver oil, iron, and strychnine, and you are certainly assisting nature to the utmost.

The opium aids the patient to rest more contentedly in bed, and although it binds up the bowels, they naturally under this absorbable diet do not move under two or three days, and what harm if we prolong it a day or two longer with the opium? Of course the bowels should not be locked up longer than the time when uneasiness is expressed by the patient, but we can then, by leaving off the opium for a period, and by the administration of oft-repeated doses in conjunction with an enema, soon have a comfortable passage. A good local medicine, and the one with which the author has had the best success, is a mixture of aristol and ichthyol made into an ointment and applied with an ointment applicator, or more convenient for the patient's use is to have the medicine made into suitable suppositories.

#### THE BEST TREATMENT OF HEMORRHOIDS.

STEVENS contributes a paper on this subject to the *Cincinnati Lancet and Clinic* for May 12, 1894. He thinks that internal hemorrhoidal tumors are best treated by direct removal. There are several methods proposed for the accomplishment of this. With the idea before us that the practitioner is to treat his cases without special preparation, because he does not see them often, the best method is that by ligature. Its advantages are that it is certain, and, if properly performed, safe; its disadvantages are mainly two. Sometimes, but not always, more or less distress, sometimes great pain even, is felt for a few days, and after this operation a patient is confined to bed some days.

The only instruments necessary are a pair of forceps, a pair of scissors, and a strong ligature. The improved method of Allingham is the one to employ. This contemplates the partial dis-

section of the base of the tumor towards the vessels which enter it from above. The operation should be done under an anæsthetic, with the sphincter stretched. The ligature is tied in the groove made by dissection around the pedicle thus formed and cut short. It comes away in about a week, and at the end of a second week the patient is usually at liberty. But before deciding upon this latter point, personally examine the former sites of the tumors. All patients do not get well rapidly; their cicatrizing power is feeble.

If the cases seen by the practitioner are sufficiently numerous to justify him in providing himself with the necessary instruments, he will find the clamp and cautery method of treatment an ideal one, and it has not been intended to prefer the ligature to it without some qualification of the statement of preference. While not so simple of performance, it is followed by less distress, and recovery is usually more speedy after it than after the ligature. The surgeon who permits his patients to walk out on the fourth day, however, as has been reported, does not decide for their best interest. A week or ten days should elapse, unless an examination shows the wounds healed. If resorted to, two or three precautions are best heeded. Do not use it on tumors high up in the rectum. Open the clamp slowly, and if there is any tendency to bleed, screw up the clamp and again apply the cautery. The cautery is sufficiently hot when dull red, and the part of the stump to which particular attention should be paid in applying the cautery is that farthest from the operator,—i.e., where the vessels enter.

Before either operation see that the bowels are thoroughly emptied, and after it introduce an opium suppository.

There are one or two other methods advised, but they are not all that could be desired. One of them, called after the name of an eminent English surgeon, consisting in excision of the "whole of the pile-producing areas," deserves to be forgotten, not because it is not simple, but because it is not safe.

A form of hemorrhoidal disease characterized by sessile granulations which bleed easily is best treated by the very old method of applying nitric acid. Introduce a speculum, dry the parts with gauze, and touch the whole granular surface again and again with a bit of cotton moistened with the acid, but containing so little that it will not run over the parts not diseased.

Lastly, before beginning any treatment, look out for complications. Especially in women

should the pelvic organs other than the rectum be examined. In children examine the urinary organs.

#### THE USE OF GLYCERIN IN HEPATIC COLIC.

*L'Union Médicale* for May 8, 1894, states that FERRAND reports the favorable results obtained by him in the treatment of hepatic colic by glycerin. The glycerin is administered by the stomach, and he believes is rapidly taken to the hepatic vessels. He believes it exercises a distinct cholagogue influence and tends to prevent hepatic colic. Should an attack of colic appear, a relatively large dose—namely, from  $\frac{1}{2}$  to 1 ounce of glycerin—should be administered. Ordinarily 1 to 3 drachms of glycerin each day, taken with some alkaline water, is quite sufficient to prevent future attacks.

#### AN OINTMENT FOR RHEUMATIC JOINTS.

The *Journal de Médecine de Paris* for May 6, 1894, states that BOURGET (of Lausanne) uses the following prescription about inflamed rheumatic joints:

R Salicylic acid,  $\mathfrak{z}$ iii;  
 Lanolin,  $\mathfrak{z}$ iii;  
 Oil of turpentine,  $\mathfrak{z}$ iii;  
 Lard,  $\mathfrak{z}$ iii.

On the application of this salve, Bourget claims that the pain is rapidly diminished, and he also thinks that a sufficient quantity of the salicylic acid is absorbed to produce a therapeutic influence.

#### THE TREATMENT OF DIPHTHERIA.

The *New York Medical Journal* for June 9, 1894, discusses this subject editorially by taking for its text an article in the *Journal des Sciences Médicales de Lille* for February 10, in which there is an analytical review, by DR. G. LEMIERRE, of various recent contributions to the periodical literature of the treatment of diphtheria. The writer begins with the self-evident statement that the number of new methods which are vaunted from time to time marks a lack of any really efficacious treatment of the disease, although there are many of these methods which, if we may believe their authors, produce marvellous results. He thus proceeds to summarize the treatments relied on by various writers whose publications he takes into account. Hübner, he says, paints the affected part two or three times a day, according to the

severity of the case, with tincture of chloride of iron diluted with from one to five times its bulk of water; then he washes the throat with lime-water and applies externally iced compresses, together with pieces of ice. Theoretically, tincture of chloride of iron is as powerfully antiseptic as corrosive sublimate, in so far as the micro-organisms of diphtheria are concerned; according to Loeffler, it kills them instantly in a solution of 1 to 125. Moreover, its use does not involve any danger of poisoning. In fifty-two cases treated in this way, only twice did death result, and in the cases of recovery the gravity of the disease was such in six of them that the author does not hesitate to conclude that death would have supervened under any other treatment. Rosenthal gives chloride of iron internally, in a two-per-cent. solution, with the addition of glycerin, from a teaspoonful to a dessertspoonful every hour, day and night. He thinks the measure unailing in preventing the angina from extending to the larynx. The temperature falls within twenty-four hours, the pulse becomes normal, the general condition is good, the pain is diminished, and the appetite is increased. In seventy-nine cases thus treated, only seven children died. Braun also uses sesquichloride of iron, but he is of the opinion that internal treatment alone is not enough. In order to destroy the false membranes more surely and more rapidly, we should not employ a solution, but an ointment, consisting of ten parts of sesquichloride of iron and twenty parts of lanolin ointment. Two applications in the course of the day often suffice, but occasionally three are necessary. Amelioration commonly shows itself within the first twenty-four hours, and at the end of three days the disease is jugulated. While with the ordinary methods of treatment he had observed forty per cent. of deaths, he witnessed only a few with this new method.

Hornig paints the throat two or three times a day with a thirty-per-cent. watery solution of pyoktanin, and then directs the patient to take a drink at once, but not to gargle. In children it is well to avoid as much as possible allowing them to expectorate after the painting, so they should be left in bed and not carried in the arms, with the head low and the legs raised, which favors the expulsion of the pyoktanin and hinders its absorption. The drug acts slowly and counteracts the poison already formed in the system. When the disease invades the nasal passages, he applies cotton tampons imbued with the same solution. He reports one hundred and forty cases thus

treated; one hundred and ten observed by himself terminated favorably.

Tullé touches the false membrane every three hours with cotton tampons impregnated with a 1-to-500 solution of corrosive sublimate slightly acidulated with tartaric acid. He remarks that it is useless to seek to remove the false membrane, for it becomes detached spontaneously on the third or fourth day. At the same time he administers regularly every half-hour  $\frac{1}{10}$  grain of calomel, a grain of sodium bicarbonate, and  $\frac{3}{8}$  grain of ipecac until an abundant action of the bowels is produced, and thereafter repeats the dose every two hours. Besides, he gives quinine sulphate, calcium chloride, calcium citrate, and iodide of iron, in varying proportion, according to the patient's age. With this treatment he reports the loss of only two children out of thirty-three.

Pilière sprays the pharynx every two hours during the day and every three hours at night with a 1-to-500 solution of corrosive sublimate in children over two years old, and with a 1-to-1000 solution in those that are younger. He has never observed any symptoms of mercurial poisoning. He raises the pharyngeal false membranes after touching them with a tampon of absorbent cotton soaked in a 1-to-30 solution of nitrate of silver. Out of ninety-eight cases, in six of which tracheotomy was required, ninety-four ended in recovery.

Wissing employs inhalations of turpentine. He causes water to be boiled day and night in the sick-room, and adds turpentine to the water, using about six ounces in the course of a day. He also makes the patient inhale the mixed vapor directly, and says that in thirty-six hours the false membrane disappears and that poisoning never occurs. Flahaut paints the false membrane every hour or two with petroleum, taking care not to use enough of the liquid for it to trickle into the larynx. Immediately after this procedure he removes the false membrane, which seems to have become detached and dissolved under the action of the petroleum. Forty cases thus treated all terminated favorably, while in the same epidemic thirty cases treated by him according to the ordinary methods resulted in twenty-one recoveries and nine deaths.

#### A PRESCRIPTION FOR HEPATIC COLIC.

The *Journal de Médecine de Paris* for May 6, 1894, recommends that poultices containing medicinal ingredients be employed, as,—

R Turpentine, ℥iii;  
Chloroform, ℥iii;  
Laudanum, ℥vi.

This should be applied over the liver.

Or that a compress of flannel wrung in water and medicated with 10 or 20 drops of chloroform be applied in its place. Every half-hour the following mixture may be given :

R Antipyrin, gr. vii to gr. xv;  
Chloroform water, ℥i;  
Cinnamon water, ℥iii;  
Hoffmann's anodyne, ℥i;  
Tincture of belladonna, gtt. x;  
Tincture of orange, ℥ii.  
To be taken at a dose.

If this mixture be vomited, the patient may be given by inhalation a little ether or chloroform, and the following injection administered by the rectum :

R Chloral, gr. vii to gr. xv;  
Wine of opium, gtt. i to gtt. iv;  
Distilled water, ℥i.

A tenth to a quarter of a grain of hydrochlorate of morphine should be given hypodermically. In the course of an hour a small glass of milk, to which has been added two to four drachms of oil or glycerin, may be added, which should be followed in turn by a full purgative dose of castor oil. Between the attacks it is well to administer full doses of bicarbonate of sodium, to order bitter tonics, and to give a mixture containing ether and turpentine, which are supposed to exercise antilithic effects. A useful prescription to take in the morning early is one composed of sublimed sulphur, cream of tartar, magnesia, of each, six drachms; oil of anise, fifteen drops. Or small pills of podophyllin containing one twelfth to one-eighth of a grain may be administered. Large rectal injections of cold water are also of value. Twice a week it is well to give one to two ounces of olive oil flavored with some peppermint for the purpose of aiding in the expulsion of any small stones. The articles of food which are permitted are milk, cream and custards, bouillon, vegetable soup, eggs, small quantities of meat, particularly chicken and veal, potatoes, boiled fish, bread in small quantities, dry white wine, and any effervescing alkaline mineral water. The articles of diet which are to be forbidden are butter and fats of all kinds, pork, mushrooms, pastries, confections, peas, all sorts of greasy foods, carrots, asparagus, tomatoes, all fruits containing much sugar, all liquors, coffee, tea, strong beers, and strong alcoholic drinks in general. A similar prescrip-

tion to that already given which contains antipyrin is also useful in nephritic colic, according to this article.

#### OBSERVATIONS ON NOSE-BLEED AND ITS TREATMENT.

KOHN, of New York, contributes an article on epistaxis to the *Medical Record* of June 9, 1894, and thinks that in considering the treatment, in view of the etiology, it is proper to consider, first, prevention, and, secondly, the means for causing the cessation of the bleeding.

In the case of a patient giving a history of repeated bleedings without any sufficient exciting cause, a most searching examination of the nose and naso-pharynx is essential; if an erosion or varicosity be found, as it frequently is, on the lower anterior portion of the cartilaginous septum, this should first be dried with absorbent cotton and then cauterized with a saturated solution of chromic acid, as advised by Bosworth and Bresgen. Chiari claims to have found such a lesion in seventy out of eighty-one cases of habitual nose-bleed, and advises the galvano-cautery beyond all other measures. The writer has seen the galvano-cautery cause nose-bleed so frequently that he hesitates to recommend it in these cases to the general practitioner. Angiomatous growths have been the cause, in some cases, of such profuse and repeated hemorrhages as to bring the patient to the verge of syncope; their radical destruction by the flat galvano-cautery is effectual in checking the recurrence of bleeding. Tumors, vascular polypi, adenoid vegetations, enlarged tonsils, if found in a patient suffering from habitual nose-bleed, must be removed.

If the child be a "mouth-breather," attention should be directed to the naso-pharynx and the adenoids, which in all probability will be found removed. Under prevention, the treatment of the generation conditions named under etiology must be considered,—viz., anæmia, chlorosis, hæmophilia, diseases of the heart, lungs, pleuræ, parenchymatous organs, etc., into which it is not the province of the writer to enter. It is mentioned for the purpose of emphasizing the necessity for a thorough physical examination of every patient suffering from nose-bleed. Suffice it to say, that if habitual constipation exist, the bowels should be regulated by mild salines; that in an enfeebled state of the system, iron, quinine, strychnine, the mineral acids, cod-liver oil, may be administered according to the indications. Fresh air, exercise in the open air, and bathing, either in fresh or salt water, are to be commended in

patients who are debilitated by repeated bleedings.

As has been mentioned under the etiology, there are still left, however, some cases in which the bleeding occurs spontaneously, without any lesion being discoverable. These occur more especially in growing children, who otherwise are in good health. Ergot has been recommended as a preventive in these cases by Morell Mackenzie. The writer has found in the fluid extract of *hydrastis canadensis* a sovereign remedy in these cases; he has had occasion to use it in a large number of cases of nose-bleed in the German Poliklinik, and has found it efficacious in preventing a recurrence in a large majority of cases. It is administered internally in 10-drop doses, in water, every two or three hours. This apparently simple treatment can be recommended with confidence in the cases above mentioned. The alkaloid hydrastinin, in the form of a hydrochlorate, has been put up in tablet form in  $\frac{1}{10}$  grain doses, and in combination with ergotin, and is a most elegant method of dispensing the drug. The *hydrastis* is prescribed, be it understood, as a preventive for the patient who at the time of his visit is not bleeding from the nose, but who gives a history of repeated bleedings. A five-per-cent. solution of the fluid extract of *hydrastis* in water may be used as a spray for the nose; it may also be used with liquid vaseline, albolene, or kindred preparations, as a spray or brushed into the nose. The drug seems to "tone" the mucous membrane, and by reason of its containing a bitter principle it has, when taken internally, a beneficial effect on the stomach, as is attested by the improved appetite following its use. Its only drawback is, that it has a tendency to cause constipation, but this may be combated by mild salines.

The thorough examination of the nose and naso-pharynx for a local lesion to account for the bleeding is not the less necessary because of the use of *hydrastis* or any other remedy which may produce a cessation of the bleeding for the time being; for, if an erosion or vascular growth be the source of the hemorrhage, the only rational course is to attack it locally. It is not always possible to find such a lesion, nor have we at all times the instruments with us for making a thorough examination. In these instances the fluid extract of *hydrastis* will be found a most reliable remedy temporarily.

Under the heading of prevention should be considered also the general laws of hygiene,—pure air in school- and sleeping-rooms, bathing, assimilable food, etc.,—to which it is unnecessary to call your attention.

So many different methods of checking an attack of nose-bleed have been recommended that a review of them will be in place before the writer describes the simple procedure which he has in most cases found satisfactory. The various methods of treatment which have been recommended may be divided into (1) non-medicinal and (2) medicinal.

Non-medicinal methods are: 1. External compression upon the bleeding nostril either by the fingers, iced cloths, ice-bags, or ice. 2. The hot nasal douche, the water having a temperature of 90° F., injected until it emerges from the non-bleeding nostril unmixed with blood. 3. Ice in the mouth, cold cloths, ice, cold metals applied to the spine, immersing the scrotum in iced water. 4. Chapman's bags, containing water at a temperature of 105° F., to the spine. 5. Cups or blisters to the hepatic or renal regions; mustard plasters to any part of the body or extremities for producing counter-irritation.

Medicinal treatment may be by: 1. Astringents in form of powder, insufflated, applied with brush or by means of the spray,—viz., the preparations of iron, the muriated tincture, Monsel's solution, diluted with glycerin; glycerite of tannin, solutions of sulphate of zinc, acetate of lead, sulphate of copper, kino, catechu. 2. Escharotics and caustics. In order to properly apply these, the blood must be rapidly touched off with pledgets of absorbent cotton or lint, so as to expose the bleeding point to view; this may then be touched with a saturated solution of chromic acid, a sixty-per-cent. solution of nitrate of silver, or a crystal of this salt may be fused on a silver probe and be thus applied; nitric acid (which must be used with great care), or the galvanocautery.

Finally, internal compression has been recommended:

1. By means of absorbent cotton pledgets, introduced into the nostril until the bleeding ceases; the number of pledgets should be counted, so that none are left behind when they are removed; or they may be connected by a strong thread, which simplifies their removal; they may be saturated with astringents in solution,—i.e., tannin, acetate of lead, sulphate of copper, etc.

2. By means of long, narrow strips of iodoform gauze, gently introduced into the bleeding nostril until this is entirely occluded, leaving the end of each strip visible at the anterior nares.

3. By means of small rubber bags, on the principle of Barnes's dilators, introduced into

the nostril empty, and then inflated with air or filled with cold water.

Finally, plugging of the posterior nares with Bellocq's canula; this should be the *dernier ressort*, and under no circumstances should be tried unless all other means fail, as it is itself not devoid of danger; cases of erysipelas, gangrene, sepsis, and even tetanus have been reported as following its use.

The writer recalls the case of a man whom he saw one week after the posterior nares had been plugged; the physician who had introduced the tampon could not remove it, it had become so tightly wedged, and was so fetid that the patient suffered from infection, and said he preferred the bleeding to the treatment. It was with difficulty that the plug was finally removed.

A twenty-per-cent. solution of antipyrin, a ten-per-cent. solution of cocaine, applied by means of cotton pledgets, which are allowed to remain *in situ*, have also been recommended as reliable remedies to stop the bleeding.

The various methods above mentioned certainly form an imposing array.

It has seemed to the writer that the simple rules for the stoppage of capillary hemorrhage are applicable to these cases; the object is, as in hemorrhage, to secure coagulation at the point of bleeding and to keep the clot in place.

The first rule, therefore, is to place the patient, and more especially the bleeding part, at rest; nervousness or fright should be quieted with assurances that there is absolutely no danger; the patient should sit upright in a chair, the head thrown slightly backward; all bands about the neck should be loosened, in order that the circulation may be unimpeded; the patient should then open the mouth as widely as possible, and should breathe through the mouth only; breathing through the nose should be entirely suspended until bleeding ceases, and should be superseded by oral breathing; blowing the nose, hawking, and spitting must be strictly interdicted; we all know how prone patients suffering from nose-bleed are to do these things. In following the instructions thus far given, the interior of the nose is placed at rest and the first indication is fulfilled; whereas, if the patient snuff up cold water, wipe or blow the nose, he displaces clots and favors the continuance of the hemorrhage.

The second rule is to tell the patient, his mouth being kept wide open, to breathe more deeply and more rapidly than he normally does; the respiration may be increased to 30

per minute; the immediate effect of this increased oxygen supply is to increase the force and frequency of the heart's action, and presumably to increase the amount of blood in the pulmonic circulation at the expense of the cerebral; whether it be due to the more thorough equalization of the blood-supply to the body and head, or to the increased muscular action incident to the increased respiratory effort, it has seemed to the writer that the nasal mucous membrane is depleted to some extent by this procedure.

The use of opium and digitalis in hæmoptysis is to a certain extent attended by the same result here obtained,—viz., a more powerful contraction of the heart-muscle.

As soon as the patient tires of the rapid breathing—which he does very soon, perhaps after thirty respirations—he may breathe normally for a few moments, when, if the bleeding has not ceased, he is told to breathe rapidly again; the mouth is to be kept open constantly, and any blood flowing into the pharynx is to be swallowed.

The fact that blood is withdrawn from the brain by this procedure is attested, in the opinion of the writer, by the dizziness which most patients experience when they resort to it, and by the pallor which the face assumes; the same symptoms have been noted by every physician during prolonged auscultatory examinations of the chest; some patients are apt to faint during such examinations; it seems to the writer that a temporary anæmia of the brain is the cause of the phenomena.

The final rule is to tell the patient to enunciate the broad vowel "A" with each expiration; the soft palate is thus brought in contact with the posterior wall of the pharynx during each expiration, the posterior nares are separated from the pharynx, and the blood is prevented from flowing into the œsophagus during the expiratory periods.

The three principal factors in this simple method of arresting nose-bleed are: first, to place the nose at rest by suspending breathing through it; second, rapid and profound respiration, acting as a respiratory and cardiac stimulant, more equally distributing the blood throughout the systemic and pulmonary circulation by abstracting it from the head; and, third, the occlusion of the posterior nares during the entire expiratory period by the intonation of the broad vowel "A" during expiration.

This method is so easily applicable that after every operation in the nose attended by bleeding the writer makes use of it; it is so much

cleaner and simpler after the snaring of a vascular polyp or the removal of an exostosis to make use of this procedure than to apply astringents that interfere with the field of operation, that it is invariably tried by the writer before any other means are applied. Of course it may in some cases of severe bleeding from a larger vessel fail; in these I would then try first the insufflation of tannin, and if this fail, the tamponing of the nostril with long, narrow strips of iodoform gauze, dipped in the glycerite of tannin, with the ends hanging out of the nostril. It is needless to dwell on the advantages of a method of arresting nasal hemorrhage in which no drugs or instruments of any kind are necessary. A few weeks ago the writer had occasion to see a severe attack of nose-bleed occur during the course of typhoid fever; had he been compelled to send to his office for instruments, drugs, etc., the patient might have succumbed in the mean time; the simple method above described had the effect of arresting the bleeding at once.

Astringents in reality cannot cope with a severe nasal hemorrhage, as the clot formed by most of them, especially the preparations of iron, does not extend down to the bleeding-point; they induce superficial coagulation, and some of them produce such a dirty, grumous compound that the field is obscured, and even though the bleeding stop, the patient feels extremely uncomfortable.

#### AN INJECTION IN DYSENTERY.

R Boric acid, ℥ss;  
Tannic acid, gr. xlv;  
Tincture of opium, gtt. xv;  
Water, Oi.

To be given after a dose of castor oil for the purpose of washing out the bowel.

#### COLLODION FOR RHEUMATISM.

The following prescription is recommended by the *Journal de Médecine de Paris* for May 6, 1894:

R Salol,  
Ether, of each, 4 parts;  
Collodion, 30 parts.

To be painted about the painful and inflamed joint.

#### PIGMENTATION OF THE SKIN DURING EXHIBITION OF ARSENIC.

M. RICHARDIÈRE (*Medical Press and Circular*, May 30, 1894), showed a patient in whom Fowler's solution, administered during only

four weeks, had caused a very marked brown pigmentation of the skin. The doses had been gradually increased, and the pigmentation displayed itself on the eighteenth day. In a few days it became well marked. It affected the skin only, not the mucous membranes. It was much more marked in some regions than others. These were the axilla, the neck, the dorsal aspect of the fingers and toes. There existed also a large number of pigmented lenticular spots, which appeared at parts where the skin had been previously bitten by insects or wounded in similar ways.

#### VARICOCELE: NEW WAY OF TYING THE VEINS.

In operating on a patient for varicocèle, Mr. MACREADY employed a method for ligaturing the veins which has been suggested by Dr. Malcolm, the anæsthetist of the hospital. The operation was performed by an incision just above the external ring, going up towards the internal ring. Mr. Macready next isolated the vas, which was held out of the way, and then freed the enlarged vein; this was then held up in the form of an inverted V, a loop of silk was passed under the V, then (after being opened) over the instrument holding up the V, and down each side of it, one free end of the silk being next passed through the loop, and both free ends securely tied, thus forming the Staffordshire knot; the portion of veins above the ligature forming the apex of the V was then cut off, and the whole wound closed. By this method the cut ends of the veins are securely attached without further ligature. The advantages claimed by this process are, that one ligature and one knot are used instead of the two ligatures and the three knots of the ordinary method of ligaturing the veins in two places, cutting away the intermediate portion, and tying the two ligatures; also that the testicle is well and thoroughly drawn up.—*Medical Press and Circular*, May 16, 1894.

#### REPORT OF THE COLLECTIVE INVESTIGATION COMMITTEE ON ANÆSTHESIA AT THE RECENT SURGICAL CONGRESS IN BERLIN.

PROFESSOR GURLT, Berlin, in presenting the report of the committee on anæsthesia, said that, on the proposition of the Society, he had carried out the investigation to a fourth year. In 1893, 63 reports had been received, of which 9 were from abroad. Fifteen reports had been sent from 21 German university clinics. The

total of last year's cases was 51,846. Of these, 32,723 were chloroform administrations, 11,617 of ether, 3896 with ether and chloroform, 750 with chloroform, ether, and alcohol (Billroth's mixture), 2769 with bromide of ethyl, 91 with nitrous oxide. The total fatalities were 20, and of these, 17 were due to chloroform. The average death-rate was 1 in 2587 administrations. The death-rate from chloroform was 1 in 1924. When the results of the previous year were added, the totals were 163,493 administrations, with 61 deaths. The rate of mortality was: chloroform, 1 in 2655; chloroform and ether, 1 in 8014; Billroth's mixture, 1 in 26,268. In fact, only 1 death had occurred from ether narcosis, and that was a case of heart-disease. In correspondence with the low death-rate from ether, its employment had largely increased of late years, from 6200 in 1892 to 11,600 in 1893. Pichet's purified ice chloroform had been used 3890 times, with 2 deaths, so it would appear that the dangers of chloroform inhalation did not lie in any accidental impurity; indeed, the facts seemed to point the other way, and that the danger was directly proportionate to the purity of the chloroform. This consideration had lately led to a different mode of administration. It had been given more slowly, and occasionally atropine and cocaine had been used with it. As regarded accidents, 255 severe cases of asphyxia had occurred, and tracheotomy had to be performed three times. König's cardiac massage, so called, was frequently used, but not always with success. Ether had, therefore, shown itself the least dangerous anæsthetic, ten times less dangerous than chloroform, but it was not without its shady side: it was dangerous in lung-affections. It was agreed to still continue the investigation.

#### A PRESCRIPTION FOR ASTHMA.

The following prescription is given by the *Journal de Médecine de Paris* for May 6, 1894:

R Chloral,  
Iodide of potassium, of each, gr. xxx;  
Water, ℥iv;  
Syrup of bitter orange, ℥vi.  
1 to 2 teaspoonfuls three times a day.

#### THE USES AND MISUSES OF ANÆSTHETICS.

SILK writes a paper on this topic in the *Lancet* for April 28, 1894. In regard to the choice of an anæsthetic, he thinks nitrous oxide, ether, and chloroform are three anæsthetics not only of very different anæsthetizing power, but the ad-

ministration of which involves very different degrees of danger. Opinions may vary widely as to the anæsthetic to be employed in any one particular instance, but we ought to regard it as a distinct misuse of anæsthetics to employ a stronger or more dangerous drug when one involving less risk would serve the purpose equally well. Here, too, while giving due weight to the nature of the operation, greater prominence should be given to the "personal equation" of the patient than is usually done. If this be done it will be found that under some circumstances a precisely similar operation may call for a different anæsthetic in different individuals. The condition of narcosis is an unnatural one, and under no circumstances can it be induced with absolute safety; although under some circumstances the risk may be so slight as not to amount to very much, still we shall do harm rather than good by attempting to ignore the dangers altogether. With nitrous oxide, for instance, the risk is reduced to a minimum; but, as one or two recent cases have shown us, an element of danger still exists. With regard to the relative safety of ether and chloroform, even the most recent utterances of the Hyderabad Chloroform Commission have failed to convince the writer that "chloroform anæsthesia is free from risk." In this connection it is interesting to note that in the years 1888 and 1889 the total death-rate from anæsthetics in England (as recorded by the registrar-general) was thirty-three and thirty-six respectively; the chloroform death-rate remaining at the same figure for each year,—i.e., thirty-two. In the two following years—i.e., in 1890 and 1891—the death-rate went up to forty-two and sixty-nine, and the chloroform rate to thirty-six and sixty-two respectively. With regard to ether, on the other hand, it is far from judicious to administer it in every case to the total exclusion of chloroform; on the contrary, its routine use is open to many objections. But even admitting many exceptions to its use, there is no doubt that from the point of view of safety, it should stand second only to nitrous oxide on our list of available anæsthetics, and that not until we have quite satisfied ourselves that it is not appropriate should we proceed to the administration of the more potent chloroform. But it has been urged, is it not better that a man should administer an anæsthetic with which he is familiar, rather than attempt to give one requiring more skill than he can pretend to, and for the proper administration of which constant practice is necessary? When the services of others possessing the necessary skill and practice are not avail-

able, this may possibly be accepted as an excuse for the individual; but it is no excuse whatever for the principle and is merely an argument, and a very powerful argument, in favor of the better recognition of systematic teaching of anæsthetics as a necessary part of the medical curriculum.

The next point to which attention is called in the misuse of anæsthetics is connected with what may be termed their mal-administration. If we could bring ourselves to admit that the induction of anæsthesia is a comparatively trivial matter, there would be no objection to relegating the duties to unskilled and youthful assistants; or, for that matter, to the nurse or even the coachman. But all the facts point against this way of looking at it, and, on the contrary, concur in inducing us to think that in any surgical operation the position of the anæsthetist is second only in point of importance to that of the operator; in fact, for the time the responsibilities involved are sometimes even greater.

In working out the statistics some years ago, the author was much struck by the fact that in the majority of instances the fatal cases recorded had occurred at the hands of men whose average standing in the profession was but little over two years. In dealing with young administrators personally, the difficulty with which one has most usually to contend is that of inducing them to concentrate their attention upon what appears to them to be the petty details of the administration; their zeal for the loftier flights of surgery rather carries them away from the matter in hand. It is usual to endeavor to correct this error by repeated insistence upon the excellent maxim that "the administration of the anæsthetic should occupy the sole and undivided attention of one man." As a corollary the administration should be in the hands of the most experienced of those who have undertaken to assist the operator; and, if it were permissible, the words might be added, "that it would often be found of advantage that a stranger should be employed for this purpose." The reason for this suggestion is that one so frequently hears of patients having taken from twenty minutes to three-quarters of an hour to get under, or of not having been properly anæsthetized during the whole course of a prolonged operation, and not infrequently this "dilatatory induction" and "under anæsthetization" are due to over-anxiety on the part of the administrator, the outcome of too intimate an acquaintance with the patient and the disease from which he is suffering. After overdosage,

which is, of course, a palpable misuse of the anæsthetic, these errors of "dilatatory induction" and "under-anæsthetization" are so serious as almost to fall into the category of misuses.

In relation to the next point, the writer refers to Mr. Christopher Heath's presidential address to the Clinical Society of London, delivered on January 25, 1889. Mr. Heath referred to what he called "the exaggerated slowness of modern surgery," and he quoted Mr. Banks, of Liverpool, and Dr. Cheever, of Boston, in confirmation of his opinion that this "slowness" is highly detrimental to the patient. As Mr. Heath expressed his opinion that this is partly in consequence of the prolonged inhalation of the anæsthetic, no more need be said of it than that the writer agrees with this entirely. It has sometimes appeared to me that the operator has had such flattering confidence in his anæsthetist as almost to forget his very existence, and surgical ardor is apt at these times to overpower all other considerations. As a result of this, undue "shock" occasionally follows the operation, even supposing that no immediate ill-effects are noticed. The use of the word "shock" leads the writer to express views not in keeping with the views of the Hyderabad Commission, which claims to have proved that "chloroform and shock are incompatibles." It is doubtful whether we can ever secure actual immunity from shock, and, even if the lighter forms are absolutely abolished, the graver ones are certainly only diminished under any anæsthetic and however far it may be pushed. If, for instance, in operations for the radical cure of hernia, or in simple oöphorectomies, careful attention be paid to the administration, it will usually be found that at the precise moment when the spermatic cord is being manipulated, or the ovary caught in the forceps, the breathing becomes shallower, the pulse flags, and possibly the pupil dilates. As far as the author's experience goes, these changes will take place with either ether or chloroform, the only differences being that under the latter the alterations are more marked and last longer. Nor are such changes prevented, though possibly they may be lessened, both in extent and duration, by the most profound degree of narcosis. In the course of the address already referred to, Mr. Heath insisted upon the importance of maintaining the strength of the patient by careful dieting and proper hygienic precautions taken before the operation as well as after, and it may have been from reading this address that the author got the idea of advising the use of

enemata of hot beef-tea about half an hour before the time fixed for the operation. This plan has been very satisfactory whenever he has had an opportunity of putting it into practice, and is particularly to be recommended when we have reason to expect that the operation will be a long and exhausting one. It is doubtful whether much real good results from the prior administration of brandy. The question of the preparation of the patient comes well within the scope of this article, because it sometimes seems that troubles and difficulties arise which are ascribed to the anæsthetic, whereas they should be more properly attributed to defects in the preparation of the patient for the ordeal which he is about to undergo. The error of underfeeding is too often committed. It is better the patient should go on the operating-table with the risk of getting sick from eating than that he should undergo an operation almost fainting from actual want of food. Then, again, a patient takes an anæsthetic a good deal better, in every sense, if he has been subjected to what one may term the "hospital régime" for a few days. This, of course, is not possible in very many instances, but the fact should be borne in mind and the suggestion acted upon whenever possible.

#### THE MANAGEMENT OF FEVERS.

In the *American Journal of the Medical Sciences* for June, 1894, BURNEY YEO, of London, writes on this subject, and in the course of his paper points out that it is well known that in the presence of putrefactive processes bacillary action is remarkably stimulated, and the intestinal lesions of typhoid fever offer a remarkable illustration of this fact. The glandular infiltration, inflammation, and ulceration observed in the walls of the ileum begin just where the intestinal contents begin to undergo putrefactive decomposition, and they become more and more intense as we descend to the ileo-cæcal valve. They are also observed in the solitary glands of the colon, but here the fluid contents of the bowels are not long retained in contact with the mucous membrane.

If we can restrain early in the disease these putrefactive changes in the intestine, we may confidently hope to restrain the morbid activity of the typhoid bacillus; and thus we see how the production of intestinal antisepsis becomes an urgent and early indication in the treatment of these cases. We are greatly indebted to Professor Bouchard for pointing out this indication so clearly and forcibly as he

has done. A calomel or other purge in the initial stage of the fever (if diarrhoea does not exist), and washing out the large intestine twice daily with naphtholated water, enter into Professor Bouchard's and the author's conception of intestinal antisepsis.

But this intestinal antisepsis cannot be carried out thoroughly without great consideration, care, and observation in the matter of feeding the patient. We must adopt a method of feeding which shall by no possibility leave a bulky residue of unabsorbed material to undergo putrefactive changes in the lower part of the small intestine, and by its presence there excite and maintain diarrhoea and provoke an extension of the ulcerative and inflammatory changes dependent on bacillary infection of the intestinal glands. For this purpose we must note carefully what digestive and absorptive activity exists in each individual case. In many this will be found to be extremely small! Let this be well noted, for the neglect to do so is responsible for much avoidable mischief. The fault usually lies in the too free administration of milk. Again and again the writer has seen milk break down utterly as a food for typhoid patients. In cases he has seen it vomited as a firm, cheesy mass soon after it has been taken into the stomach, and in many others he has observed the maintenance of diarrhoea to be dependent upon the irritation of masses of milk curd passing through the inflamed and catarrhal intestine. These are obvious instances of the failure of milk as a food. There are others, far more common, in which it will be found, if the alvine dejections be carefully examined and estimated, that nearly, if not quite all, the casein of the milk taken as food is passed undigested, not as coarse curds, but as a fine deposit from the so-called "pea-soup" stolls. Again and again he has proved this, and shown that the amount of milk absorbed is in many cases remarkably small; and to persist in giving food that is not absorbed is to persist in introducing decomposable material into the intestine when we wish to keep it free from putrefactive decomposition, and to maintain diarrhoea when we wish to keep the bowels at rest. It is the popular mania for feeding which induces us to give food when it simply passes as an irritating decomposing substance along the intestinal tube. Remember that it is useless and injurious in these cases to give food that is not absorbed. Estimate accurately the absorptive capacity of the patient. If he cannot absorb milk at all, give him some other food. If he cannot absorb four pints in the twenty-four hours, give him two; and if he

cannot absorb two pints, give him one; and if he cannot absorb more than one-half pint, give him one-half pint.

Give all food very dilute; milk should be diluted with twice its bulk of water. We wish for antiseptic and eliminative purposes to give as much pure water as the patient will drink; give it, then, as a diluent of his food. When milk, however small in quantity, absolutely disagrees, very dilute, freshly-made, clean soups, in the making of which some aromatic herbs have been used, is the best substitute. Dilute albumin water, made with the white of an egg, is also then serviceable. Give whatever intestinal antiseptic you may be using at the same time as the food, so as to keep it from putrefactive decomposition. The antiseptic principle, when applied to the feeding of typhoid patients, necessitates, then, the administration of food in a dilute form,—food that remains liquid in the body as well as outside it, and that is not prone to be suddenly rendered solid by chemical change, as undiluted milk is. The author urges the necessity of exchanging milk for other food when it is seen that much solid, though finely-reduced casein, is passing in the motions.

As to the use of alcoholic stimulants, the general tendency is to give them too early and in too large quantities. They are needed in moderation towards the end of the most severe and protracted cases, but the less severe cases do better without any. He has used in association with moderate quantities of alcohol, in protracted cases, with marked cardiac debility, infusion of coffee, with more marked and sustained stimulation of the heart, than when alcohol alone has been given.

It is not to be expected that success will uniformly attend the above method of treatment—*i.e.*, an antitoxic or antiseptic method—unless we are enabled to apply it early in the disease. Every day, every hour that is lost in allowing the products of the infective microbe to be diffused widely through the system will tend to lessen the efficacy and minimize the effects of our medicinal antagonists.

If time is lost at the onset, the virus becomes diffused, and an intense general infection may occur; and then, if the individual tissues are especially sensitive to the virus, no remedies may be able to prevent the occurrence of a fatal lesion, such as excessive hemorrhage from deep ulceration or perforation. One great advantage in establishing complete intestinal antiseptics, and in attempting for this purpose to give just as much food as will be absorbed and no more, is that we are enabled, in

the advanced period of the disease, to keep the intestinal canal at rest, a most important indication in connection with the intense ulcerative processes which are usually present there in severe forms of typhoid. The writer gives, for this purpose, small enemata of two or three ounces of starch mucilage, each containing about ten grains of tannin and five grains of Dover's powder. This not only allays intestinal irritability, but it is useful in quelling nervous excitement also.

The free use of depressing antipyretic agents merely as reducers of temperature is objected to, as they simply attack a symptom, and they should be reserved exclusively for those cases in which the symptom they attack is for the moment the all-important symptom of the disease,—*viz.*, for states of hyperpyrexia. For this purpose, occasionally, but very rarely, he uses a small dose of phenacetin (5 grains). Even in such small doses the resultant great cardiac depression is at times alarming.

With regard to the routine cold-bath treatment of typhoid, the author passes it without comment, further than stating he has seen calamitous results occasionally follow its indiscriminate application. Its essential value in certain cases of hyperpyrexia is not to be doubted. It, however, attacks a result of the disease only; it is not wholly free from risks of its own; it is difficult to apply continuously, and unless applied continuously, often fails to reduce temperature, except for a brief period. As a tiresome and inconvenient method of treatment, its great claim to adoption was the superior results it was stated to yield.

#### PENTAL.

MR. T. E. CONSTANT read a paper at the Odontological Society recently on "The Production of General Anæsthesia for Dental Operations by Means of Pental." He remarked that pental is a new drug only as regards its name and method of preparation; it is, in fact, the amylene of Snow. The manufacturer, C. A. F. Kahlbaum, of Berlin, claims for it a definite and unvarying chemical composition and freedom from all impurities. Pental, or isoamylene,  $(\text{CH}_3)_2\text{C}.\text{CH}.\text{CH}_3$ , is a colorless liquid of low specific gravity, having a constant boiling-point of  $38^\circ \text{C}$ . It is obtained from amylene hydrate by heating with acids. It is insoluble in water, but mixes with chloroform, ether, and alcohol. It is extremely volatile and inflammable. It has a peculiar and somewhat disagreeable odor, but is so little irritating that the pure vapor can be inhaled

without the slightest discomfort. In his early experiments, Mr. Constant endeavored to induce anæsthesia by the open method,—that is, by pouring the drug upon a piece of lint lying in a cone-shaped holder; but this he found unsatisfactory owing to the waste of time and the quantity used. Subsequently he devised an apparatus somewhat on the principle of the Ormesby inhaler. In the majority of cases the following phenomena were noticed: Almost immediately the pental was inhaled there were slight flushing of the face and quickening of the pulse, the increased frequency being unaccompanied by any diminution of force. Respiration, if quiet at the commencement of the inhalation, became deep and rapid when the handle of the inhaler was turned full on, but became quieter when it was turned off. The eyes, if closed, opened as the patient became anæsthetized, and had a fixed and staring look. The conjunctiva reflex was rarely lost, although in some cases it was absent after four or five inspirations. In a few instances there was profuse perspiration after about thirty seconds. The duration of the anæsthesia produced was on the average of about one and a half minutes, but varied greatly with the patient and with the character of the respiration, never having been less than a minute or more than three; there was no muscular relaxation. Occasionally the patient's eyes would follow the movements of the operator; otherwise the patient remained quite still. In about five of the one hundred and forty cases the patients declared they were perfectly conscious throughout, but felt no pain and had no desire to move. There were no after-effects, immediate or remote, in any one case where it was administered in this way. However, he had had cases where dangerous symptoms arose, and recently three fatal cases had been reported.

In conclusion, Mr. Constant said that whatever may be the safety of pental as compared with chloroform, there can be no doubt that it is more dangerous than nitrous oxide, and that the last-named agent should invariably be chosen for brief operations. Nevertheless, he was of opinion that those of the medical profession who are in the habit of administering chloroform for operations where nitrous oxide or nitrous oxide and ether could be used equally well should give the preference to pental, because, even if it be no safer than chloroform (and personally the writer believes it to be far more so), the ease of its administration, the certainty of its action, the rapidity of recovery after its use, and the entire absence of after-effects entitle it to a claim upon the considera-

tion of those who deem chloroform a justifiable anæsthetic in dental surgery.—*Lancet*, April 28, 1894.

#### TOXIC SYMPTOMS PRODUCED BY ANTI-PYRIN.

HOOD reports in the *Australian Medical Gazette* for May 15, 1894, a case of this character.

Mrs. R. W. Y. had been under treatment for some months, suffering from a very persistent and generalized lichen ruber. Intense itching and irritation were marked features of the case. During the course of the disease she was attacked with influenza, headache and pain in the back being excessive. Antipyrin (5 grains) was ordered given every two hours till relieved. After the first dose the itching and irritation of the skin became much worse. According to directions, the patient took a second dose after the two hours were up; the effect of this was indeed dire. The itching and irritation became so extreme as to render the patient exceedingly ill. Every part of the body, even those which had been healed for some time before, became crimson, and the following morning the disease seemed to be as bad as it had been months previously. Before administering the antipyrin the case had been progressing satisfactorily, and at least two-thirds of the body had recovered from this comparatively rare affection,—lichen ruber. Only ten grains of antipyrin were taken altogether, yet with such serious effect. After its discontinuance the case went on quickly to the stage before antipyrin was used, though for some time the amount of scaly *débris* given off by the skin was much greater than before. The lichen ruber has now entirely disappeared and the patient is perfectly well.

#### THE TREATMENT OF INCONTINENCE OF URINE IN CHILDREN.

According to *La Tribune Médicale* for May 26, 1894, the following treatment is advisable. After urging the necessity of patience in the treatment of such cases, it is directed that the child shall take milk, alkaline waters, cold douches, if strong enough, and that any anæmic symptoms shall be overcome by proper treatment. Where the incontinence seems to depend upon atony of the sphincter, electricity may be used, the negative pole being placed in the urethra and the positive pole over the pubis. Very feeble currents may be passed for from one to five minutes once a week. Generally twelve to fifteen applications of this kind suf-

fice. It is also well to administer strychnine carefully in such cases, or the following may be used :

- R Extract of nux vomica, gr. iv;  
Reduced iron, gr. xv;  
Powdered geranium, gr. xv.

Make into twenty pills and take 1 to 3 a day.

Or we may prescribe,—

- R Ergotin, gr. viii;  
Powdered aloes, gr. ss.  
Take 1 pill once or twice a day.

In those cases where there is irritability of the bladder, the treatment with belladonna is applicable, and the following may be used :

- R Extract of belladonna, gr. iii;  
Camphor, gr. xv;  
Castor, gr. xv.

Make into twenty pills and take 1 at night.

Or this prescription may be used in the form of a suppository. In still other instances, bromide of potassium, in the dose of 30 grains at night, may be employed; 10 to 15 grains of antipyrin used.

#### TREATMENT OF PILES BY KOSO-BUDKI'S MODIFICATION BY CHRYSAROBIN.

McLEOD reports a case of hemorrhoids treated in this manner to the *Australian Medical Gazette* of May 15, 1894.

W. M., aged 40, suffered from internal hemorrhoids for twelve years. They used to prolapse every few weeks, and especially if he indulged unduly in alcohol. He says he got relief only when they "burst," causing loss of a considerable quantity of blood. Then they did not trouble him till the next prolapse.

In January, 1893, he began using suppositories made in accordance with the following formula :

- R Chrysarobin, gr. i;  
Iodoform, gr.  $\frac{1}{4}$ ;  
Ext. belladonna, gr.  $\frac{1}{8}$ ;  
Coca butter, gr. xxx;  
Glycerin, q. s. ft. suppositor.;  
Cocaine hydrochlor., gr.  $\frac{1}{4}$ .

He used altogether three and a half dozen of these—one daily. The hemorrhoids gradually diminished in size from January till May, at which date they disappeared, and he has had no return since then. He can indulge in drink freely without inducing an attack.

An important adjunct to the treatment was the "squatting" position at stool, which he was induced to adopt. He has gained in weight, and feels better in every way.

#### SYPHILITIC EPISCLERAL GUMMA.

DEMICHERI (*Annales d'Oculistique*, June, 1894) describes two cases of episcleral gumma of the episcleral tissue. He thinks that the cure of this affection is generally effected in about two months, although the duration may be shortened by proper treatment, and under vigorous antisyphilitic remedies the disappearance of the infiltrated area is very remarkable. This treatment necessarily includes the rapid mercurialization of the patient.

#### THE NASO-PHARYNGEAL TREATMENT IN OCULAR AFFECTIONS.

GUIBERT (*Annales d'Oculistique*, June, 1894) calls attention to the relation between pathological conditions in the naso-pharynx and various ocular lesions, particularly ulcerations of the cornea and lachrymal disease, and concludes that the treatment of the naso-pharynx is of paramount importance. This should include :

1. Antisepsis of the nasal passages.

2. Operations on the nose and pharynx,—for example, the removal of polyps, vegetations, and hypertrophies. If these measures are carefully pursued, astonishingly rapid results will be obtained in the cure of these affections.\*

#### FORMULAS.

For mild conjunctivitis :

- R Boric acid, gr. x;  
Biborate of sodium, gr. iv;  
Distilled water, f $\frac{3}{4}$ i.

Sig.—Use freely three times a day.

For conjunctival hyperæmia :

- R Boric acid, gr. x;  
Hydrochlorate of cocaine, gr. ii;  
Rose-water, f $\frac{3}{4}$ ss;  
Distilled water, f $\frac{3}{4}$ ss.

Sig.—Use freely three times a day.

For subacute conjunctivitis :

- R Biborate of sodium, gr. viii;  
Camphor water,  
Distilled water, of each, f $\frac{3}{4}$ i.

Sig.—10 drops every four hours.

\* The importance of the relation of nasal disease to ulcerations of the cornea, particularly of the phlyctenular type, as well as to disease of the lachrymal passages, has frequently been referred to in the Progress columns of the THERAPEUTIC GAZETTE, as well as in the Leading Articles. There is scarcely any doubt that many, if not most, of the examples of phlyctenular keratitis practically depend upon naso-pharyngeal disease, and can only be radically and thoroughly cured when this relationship is taken into consideration with the local therapeutic measures.—ED.

The following formulas are recommended by Mittendorf:

For simple blepharitis:

R Red oxide of mercury, gr. x;  
Vaseline, f3ss.

Sig.—Apply to the edge of the lid at bedtime.

Or,

R Ammoniated mercury, gr. xx;  
Powdered camphor, gr. x;  
Vaseline, f3ss.

Sig.—Apply at night.

Or,

R Solution of subacetate of lead, gtt. x;  
Ointment of rose-water, giii.

Sig.—To be used for the more chronic forms of marginal blepharitis.

#### PARTIAL SUPPRESSION OF THE EMPLOYMENT OF COLLYRIA.

In another portion of the THERAPEUTIC GAZETTE we have referred to De Wecker's protest against the uselessness of collyria in the treatment of corneal ulceration under many circumstances. In the *Annales d'Oculistique*, June, 1894, appears another article upon this subject, in which the following points are again enumerated:

1. Disinfection of the lids and especially of the palpebral border and the roots of the cilia.
2. Curetting of the ulcers, with irrigation of the infected area.
3. Injections beneath the conjunctiva and in the neighborhood of the infiltrated area with some drops of a solution of sublimate (1 to 1000).
4. The vigorous application of an occlusive bandage without the use of collyria. This bandage should be applied with antiseptic precautions.

#### SUBCONJUNCTIVAL INJECTIONS OF SUBLIMATE IN OCULAR THERAPEUTICS.

To the numerous reports which have already appeared upon this subject, and many of which have appeared in the THERAPEUTIC GAZETTE, may be added an abstract of a thesis by RIBEIRO DA SILVA (*Annales d'Oculistique*, June, 1894), who, after enumerating the various methods of administering mercury,—namely, frictions, ingestion by the mouth, hypodermic injections, and fumigations,—traces the history of the employment of subconjunctival injections and describes the advantages and disadvantages of the treatment. According to him, the employment of sublimate thus introduced into the eye is of use, and he supports his opinion by a number of observations, which are thus classified:

1. Affections of the cornea, interstitial keratitis, and ulceration with infiltration.
2. Ocular affections consecutive to the operation of cataract.
3. Episcleritis with corneal complications.
4. Iritis.
5. Syphilitic irido-choroiditis.
6. Choroiditis with opacities in the vitreous humor.
7. Choroido-retinitis.
8. Hyalitis.
9. Absolute glaucoma. In one case a patient had had sclerotomy performed on the right eye, and violent pain in the eye was relieved by a single injection of sublimate. In a second case precisely similar pains disappeared completely after three subconjunctival injections.
10. Neuro-retinitis. In all of these affections the author, by employing the sublimate injections after the manner described by Darier and already reported in these columns, obtained excellent results.

#### EVISCERATION BULBI.

ELISABETH WOLKOMITSCH (*Annales Suisses des Sciences Médicales*, 1 Série, Liv. 8), after giving a complete exposition of the facts known in regard to evisceration, proceeds as follows:

1. Exenteration of the bulbus is generally more easily and rapidly accomplished than enucleation, in which the separate tendons must first be found and cut. [This is an astonishing assertion.—ED.]
2. Exenteration avoids the danger of meningitis, as so far no case of this complication has occurred after operation.
3. The stump left after exenteration is larger and moves more readily than that after enucleation. It is also painless and very favorable for prosthesis. [The investigations of Hotz, of Chicago, which will be found in the Detroit letter of the THERAPEUTIC GAZETTE, July, 1892, demonstrate the inaccuracy of this statement.—ED.]

Dr. Wolkomitsch thinks that the objections to this operation—namely, the greater reaction and the longer period of time which elapses before recovery takes place—are neutralized by the improvement which is obtained; for example, the appearance of the closed eye, even after removal of the artificial eye, is said to be much less disfiguring than after enucleation.

She thinks all ophthalmologists are in accord, that in cases of panophthalmitis exenteration is the only method to be adopted. According to Bunge and Braunschweig, enucleation is in-

licated in intraocular tumors which have not perforated the sclerotic nor reached the extra-orbital space, and in disease of the bulbus which tends towards a centripetal development; for example, sympathetic ophthalmitis. Enucleation may also be substituted for exenteration when it is necessary to accomplish results in the shortest possible time without regard to cosmetic effect. Optico-ciliary neurotomy may be employed in cases of certain glaucomatous eyes which are painful, but which cannot propagate inflammation. According to Braunschweig, exenteration should be done in cases of staphylococcus degeneration, in panophthalmitis, in foreign bodies in the interior of the eye, iridocyclitis, glaucoma, and sympathetic ophthalmitis; and Bunge further thinks that the operation may be used in cases of phthisis bulbi, especially when they cannot endure the insertion of an artificial eye.

According to Guaiata, the absolute indications for enucleation are malignant tumors and sympathetic ophthalmitis, and for exenteration panophthalmitis and interocular suppuration in general. The relative indications for enucleation are painful phthisis,—especially when it is traumatic, associated with foreign bodies,—and for exenteration hydrophthalmos, staphylococcus, absolute glaucoma, and hemorrhagic glaucoma.

Schweigger performs enucleation in cases of malignant interocular tumors, when sympathetic irritation has begun, resection or enucleation, and in all other cases exenteration. According to this author, exenteration is preferable to enucleation for severe wounds, excessive ruptures of the cornea and sclerotic, which are followed not only by destruction of the sight, but generally also by purulent irido-cyclitis and lead to atrophy of the eyes after a tedious course; for smaller wounds, with or without the presence of a foreign body in the eye, if followed by purulent choroiditis, in order to induce as quickly and painlessly as possible the inevitable result of atrophy.

#### EXPERIMENTAL STUDY OF THE GALVANOLYTIC-KATAPHORIC INFLUENCES ON THE EYE.

SCHOELER and ALBRAND ("Experimentelle Studie über Galvanolytische-Kataphorische Einwirkungen auf das Auge," Wiesbaden, 1894) come to the following conclusions:

1. The metabolism in the interior of the eye is greatly influenced.

2. In galvano-puncture we possess a means of producing therapeutic effects with tolerable

certainty in the interior of the eye, and reactive changes to a degree corresponding with the power of the current applied. Although it has been possible by this means permanently to cure a marked case of detachment of the retina associated with a high degree of myopia, no definite opinion upon the value of such a process in the cure of retinal detachment can be given, on account of the lack of a sufficient number of experiments upon the human eye.

3. The kataphoresis of potassium iodide in and through the eyeball is accomplished with changes in the interior of the eye, which (a) are different from those observed in galvanopuncture, and (b) are to be distinguished from those developed by simple galvanic current, as well by the value of the caustic action as by their greater intensity.

4. The paper urges the possibility of further studies in this line, as opening an inviting field for research.

#### OPHTHALMIC HEMICRANIA.

AUGUST SIEGRIST (*Annales Suisses des Sciences Médicales*, 1 Série, Liv. 10), after writing fully concerning the cause and situation of ophthalmic migraine, comes to the following conclusions:

The symptoms of ophthalmic migraine can only be explained on the supposition that it is caused by a vaso-motor disturbance which has a duplex localization; the symptoms of the migraine pointing to a localization in the dura, and those of the "flimmer's scotom" to one in the occipital cortex. As the causes of these symptoms he particularly refers (and in this reference we find the indications for treatment) to errors of refraction, especially astigmatism, to excessive over-exertion of the eyes, and to a congenital, often inherited, state of the vaso-motor system. Important etiological factors must be looked for in hunger, fear, excitement, cardiac weakness, etc., and their presence give indications for treatment.

#### THE PATHOGENESIS AND PROPHYLAXIS OF INTRAOCULAR HEMORRHAGE AFTER THE EXTRACTION OF CATARACT.

TERSON (*Annales d'Oculistique*, May, 1894) believes that affections of the general and local blood-vessels and increased arterial tension are the causes which determine intraocular hemorrhage, and urges the careful examination of the hearts of patients on whom the operation of cataract is to be performed, as well as of the general vascular system. If arterio-

sclerosis is marked, he recommends a prolonged course of iodides, and for a few days preceding the operation a suitable diet, moderate purgation, tincture of veratrum viride, and chloral at night. Every cause of emotion should be avoided; and, finally, in order to end the operation as rapidly as possible, a preliminary iridectomy is advisable. He does not believe that injections of ergotin during the hemorrhage are of any value.

#### *XEROPHTHALMOS CURED BY SUTURE OF THE EYELIDS.*

M. RUDINE (*Annales d'Oculistique*, May, 1894) relates the case of a patient who was affected with xerosis of both corneas. The author sutured the edges of both eyelids, except a small portion in the middle, hoping to suppress in this way the evaporation of liquids. The result was excellent. The cornea, which may be perceived through the hole situated between the palpebral edges, is transparent and bright, and the patient can see to thread a needle.

#### *EPITHELIOMA OF THE CORNEO-SCLERAL JUNCTION CURED BY INJECTIONS OF SUBLIMATE.*

MARTIN (*Annales d'Oculistique*, May, 1894) had a patient with an epithelioma of the corneo-scleral junction, which reappeared after removal, and he concluded to try injections of sublimate. Two weeks after they were begun nothing but a superficial corneal ulceration remained, which at the end of a fortnight had healed. There was a slight relapse seven months later, which yielded to renewed injections.

PARISOTTI, discussing this case, doubted whether the result was permanent, as relapse had already taken place in one instance, and he thinks a grave responsibility is assumed by the surgeon who advises one suffering from such an affection to retain his eye.

#### *SUBCONJUNCTIVAL INJECTIONS IN CERTAIN OCULAR AFFECTIONS.*

Bocchi (*Annales d'Oculistique*, May, 1894) adds his testimony in regard to subconjunctival injections of corrosive sublimate, to which reference has so frequently been made in the pages of the GAZETTE. He finds them efficacious in serious corneal ulcers without hypopyon, but believes that they have little effect in parenchymatous keratitis, plastic iritis, and traumatic irido-cyclitis. On the other hand,

syphilitic retinitis yielded to their influence. In cases where prolonged cure is necessary he regards them with suspicion, because, according to him, sublimate injected under the conjunctiva turns to calomel, and can be found in the tissues.

#### *THE TREATMENT OF EPITHELIOMA WITH CHLORATE OF POTASSIUM.*

FUMAGALLI (*Annales d'Oculistique*, May, 1894) believes that chlorate of potassium, in the form of a salve or powder, has a cicatricial effect in cases of ulcerated epithelioma. When the chlorate of potassium does not suffice to cure the neoplasm entirely, its application has some use, because it restricts the ulceration and renders the removal of tissue by operation less extensive.

#### *THE ADVANTAGES AND DISADVANTAGES OF ELECTROLYSIS IN THE TREATMENT OF STRICTURE OF THE LACHRYMAL DUCT.*

LAGRANGE (*Annales d'Oculistique*, May, 1894) thinks that electrolysis deserves to rank with Bowman's method in the treatment of affections of the lachrymal ducts, but it must not be used to the exclusion of other methods. It is useful in order to make Bowman's method easier and more complete. Weak currents should be used for two or three minutes only, as currents exceeding six or eight milliamperes create sloughs which are followed by incurable strictures. Weak currents, on the other hand, soften the mucous membrane and make the introduction of a large calibre probe an easy matter. He believes that the electrolyzer exercises a strong antiseptic influence on affections of the nasal canal. He concludes that electrolysis is a very useful method in preparing the mucous membrane for dilatation with probes; second, that it is dangerous to undertake to cause dilatation by the action of the electric current alone; and, third, that a very valuable antiseptic action is added to its mechanical effect.

#### *TREATMENT OF BLEPHARITIS BY CORROSIVE SUBLIMATE.*

ESSAD (*Annales d'Oculistique*, May, 1894), after referring to the fact that ciliary blepharitis—the blepharitis glandulo-ciliaris of Desmarres—is an affection insensible to most medications,—for example, calomel, boracic acid, red and yellow oxide of mercury, cauterization with nitrate of silver, tincture of iodine, oil of cade, etc.,—reports that he has had excellent

success with the adoption of Despagnet's method with sublimate dissolved in glycerin as a vehicle.

#### PECULIAR ACTION OF SULPHATE OF DUBOISIA.

DR. H. F. HANSELL (*Philadelphia Polyclinic*, June 16, 1894) reports the case of an unmarried girl, aged nineteen, who received, for the purpose of correcting an error of refraction, a prescription of duboisia sulphate, two grains to the ounce. After using this for one day the lids of both eyes were nearly closed by an acute inflammation of the skin and infiltration of the underlying connective tissue. During the next twenty-four hours she instilled the drug three times. When again seen, both lids were almost entirely covered by the tense, red, and swollen lids; the conjunctivæ were not chemosed, the corneæ were clear. The same duboisia was used in another patient's eyes without producing similar effects. The inflammation subsided rapidly, and her family physician reported that she had recently been under treatment for pemphigus. Dr. Hansell attributes this unusual action either to idiosyncrasy or to an irritative local action upon an individual whose blood was disordered.

#### TREATMENT OF PHAGEDENIC SYPHILITIC ULCERS.

FOURNIER (*La Tribune Médicale*, June 7, 1894), in discussing the ordinary treatment for phagedenic syphilitic ulcers, advises, where other means fail, liberal applications of iodoform covered in with cotton and rubber tissue. This is often unsuccessful. In case this fails, caustics may be applied, but even these remedies are often followed by failure. Moreover, they are inapplicable when the ulcer is extremely large, or when it is placed upon the face. Under such circumstances it is well to absolutely stop all medication for a time; then, after the patient's health has been restored, to begin again with specific treatment. These cases may be cured or resist all other means of treatment.

#### PROPHYLAXIS OF POST-AMPUTATION NEURALGIA.

WITZEL (*Centralblatt f. Chir.*, No. 23, 1894), on the basis of two dissections, came to the conclusion that post-operative neuralgia was due to fixation of the nerve-endings through the bone or in firm scar tissue. This post-operative neuralgia, particularly in the case of amputation, he proposes to avoid in the follow-

ing way: After the limb is removed, even before bleeding vessels are secured, the nerve-ends are seized and drawn out as far as possible, the soft parts being stripped back with the back of a scalpel. They are then cut high up transversely. The cut end retracts deep in the soft parts, and is especially important in Pirogoff's operation to divide the bifurcation of the tibial nerve. In shoulder-joint excision the divided extremities of the nerves should always be carefully sought for, pulled out, and cut off. Primary healing is also to be sought for as a means of preventing post-operative neuralgia, since thus there is a scar tissue.

#### REMOVAL OF TYMPANIC VERTIGO BY REMOVAL OF THE INCUS.

BURNETT (*International Medical Magazine*, June, 1894) characterizes chronic tympanic vertigo as that due to adhesions and sclerosis in the drum-cavity, with consequent retraction of the membrana tympani and the chain of ossicles, and the consequent too firm pressure of the stapes into the oval window. The cure consists in liberating the stapes. This is best accomplished by removal of the incus. The reporter has operated on twenty cases for the relief of chronic tympanic vertigo. In the first seven the membrana tympani and the malleus were removed. All cases were relieved; but since there was more or less reaction, the operator determined to remove the incus alone. Thirteen cases of chronic tympanic vertigo were thus operated on, with most encouraging results. There was more or less relief in every case. Full notes of a few selected cases are appended.

#### THIAFORM.

SCHMID (*Therap. Monat.*, April, 1894, quoted by *Deut. Med. Zeit.*, June, 1894), after having tried thiaform in the treatment of burns and as an application to leg ulcers, holds that his results justify the statement that this drug is an admirable application, since it is non-toxic, easily managed, and produces no after-effects, and since it has a special quality of hastening cicatrization even when large surfaces are granulating.

Hoffmann, writing on the same topic, holds that this drug is equalled in healing power by no other therapeutic agent. Ulcers, burns, abscesses, even chancroids, yield rapidly under its use. It is absolutely non-toxic, even when used in large quantities. It is hæmostatic, locally anæsthetic, so much so that the use of

cocaine is often superfluous. It so much lessens wound secretion that drainage is unnecessary. In addition to these many advantages, the drug is odorless and exercises a powerful deodorizing effect on foul secretions.

#### LYSOL.

ANSCHUTZ and POHL (quoted by *Deut. Med. Zeit.*, June, 1894), in inaugural dissertations upon the antiseptic value of this drug, came practically to the same conclusions in regard to it. These are that it is chemically constant, that it makes a clear solution in water, that it kills micro-organisms in dilute solution, that it does not irritate the hands of the surgeon, that it is only very slightly toxic, and that it is cheap.

#### THE TREATMENT OF SALPINGO-OVARITIS.

ANVARD (*International Medical Magazine*, June, 1894) states that he has had very satisfactory results in the medical treatment of subacute salpingo-ovaritis by distention of the vagina by tamponing. The vulva and vagina are first washed out with antiseptic solution and a cusco speculum is introduced. Into this is poured a tablespoonful of glycerin with a little iodoform to prevent decomposition. Then with a pair of pincers a tampon as large as a walnut, made of cotton firmly pressed together, is introduced; this is passed into the posterior cul-de-sac of the vagina. The lateral cul-de-sacs are tamponed in the same manner, and, lastly, a tampon is placed in the anterior cul-de-sac; thus the os is surrounded with tampons, each saturated with the glycerin which has been poured into the speculum. These tampons should remain in position for two or three days, and then should be taken out by the physician in attendance. This treatment does not interfere with micturition or defecation, nor does it entirely prevent coition. It often accomplishes cures or considerable improvement in cases which seemed doomed to surgical interference. Not only are good effects observed when the adnexa are affected, but deviations of the uterus, notably retro-deviations, are most favorably influenced.

#### TREATMENT OF SPINA BIFIDA.

VAN HOOK (*North American Practitioner*, vol. vi., No. 5) holds that iodine injection is a relic of a past surgical age, and in the light of pathological studies is no longer to be prac-

tised. The advantages of this method are its ease of application and the fair percentage of cures. The objections are, however, insurmountable. Among these may be mentioned:

1. The method is a blind one, not permitting the operator to exercise any discretion as to the disposal of nerve-elements, but compelling him to bring about obliteration of the sac by the rude method of scar formation and contraction.

2. Many deaths take place immediately from the entrance of the irritant fluid into the spinal canal.

3. No adequate protection can be given to the contents of the spinal canal by the shrivelled sac and its contents. The mere obliteration of the sac is not the sole object of interference.

For the open method the following facts may be pleaded:

1. The operator may preserve and restore to the spinal canal the errant nerve-elements.

2. The meninges can at once be accurately closed under painstaking inspection by sutures, thereby protecting the spinal cord immediately.

3. The spinal canal can, if desired, be permanently closed by plastic methods, rendering recurrence impossible and giving protection to the spinal marrow.

Furthermore, the statistics of the two methods of operating are, so far, slightly more favorable to the open method. Hildebrand sums up the recoveries from injection at sixty-six per cent., while his statistics of the open method give 73.5 per cent. of recoveries. These statistics are, as Hildebrand admits, fallacious, inasmuch as they do not include all the cases of all the operators. A better comparison of the two methods will be found in comparison of the figures given by the operators who have had the greatest experience in the two procedures. Morton's own cases of injection give a percentage of recoveries of sixty-five per cent., while König and Bayer each had 76.9 per cent. of recoveries. This result, it is true, is not far from the general result obtained by adding all the statistics together.

As to the time of operating, Bayer's conclusions, as quoted by the operator, are as follows:

1. The operation for spina bifida sacralis and lumbo-sacralis is immediately and pressingly indicated in all those cases which are born with ruptured sacs, or whose sac ruptures intra-partum or bears a zona medullo-vasculosa, and which do not show paralyses, and are not complicated with severe malformations, except

club-feet. In these cases the nervous elements of the sac are to be carefully guarded.

2. It is also to be undertaken in cases which show paralysis as soon as the child is strongly developed and danger of infection threatens from the side of the exposed medullary constituents of the sac.

3. In cases which bear a sac closed and covered by normal skin the most delicate period of infancy is to be passed by as an operation period. Still, the operation, if the child is otherwise healthy, is not to be put off too long, for fear of traumatic injuries unavoidably acting upon the sac.

The modes of operating are:

1. Simple excision of the superfluous sac-wall, with suture of the remainder of the meninges and of the skin.

2. The method of Mayo Robson and of Bayer is the same as the first method, together with suture of the muscles or fasciæ over the defect.

3. Osteoplastic or chondroplastic methods. (Seneko, Botroff.)

4. A combination of excision with suture of the sac, plastic operation upon the muscles or fasciæ, and osteoplasty.

Finally, the author reports a case in point. Child, aged five months; tumor was in the lower lumbar region, forming a thin-walled cyst about three inches in diameter. The skin was opened by two curved incisions and dissected from the cyst-walls; the cyst was fully exposed and opened to one side and its contents inspected. Numerous large nerve-trunks ran freely through the sac, to be inserted at its apex; others followed the walls of the sac. The nerves were dissected free and pushed into the spinal opening. The meningeal sac was first cut through and sutured. Two flaps were raised from the lumbar fasciæ and brought together. In order to further close the spinal opening the rudimentary laminæ of the spinous processes were nicked and arched together; strong silk sutures were used to approximate the fascial flaps. The skin-flaps were carefully brought together with fine catgut. Recovery was uninterrupted.

#### A NEW METHOD OF VALVULAR GASTROSTOMY WITH A MUCOUS-MEMBRANE LINING.

ANDREWS (*Journal of the American Medical Association*, May 19, 1894) proposes a new method of valvular gastrostomy of the mucous membrane and lining; the operation is as follows:

The stomach is drawn through the external wound; incision is made very near the upper border directly downward about two inches; the lower part of the anterior wall is raised, turned out through the incision, and spread out flat. Over the lower end of the cut two incisions are made through the loose mucous membrane, one to the right and the other to the left, each extending about three-quarters of an inch laterally from the main incision. From the end of each of these two mucous-membrane incisions another cut is made downward through mucous membrane parallel to the axis of the body, about one and a half inches long. At the lower end the two incisions are turned at right angles towards each other, but not meeting, the separation of one-quarter of an inch being left between them. A velvet-eyed English catheter (No. 10 English scale) is laid along the middle of the quadrangle of mucous membrane mapped out by the last incision, and is allowed to project about one inch below. Two flaps of mucous membrane are then turned up from each side over the tube, free edges being secured to each other by Lembert stitches placed so as to turn the mucous surfaces in and bring the connective-tissue surfaces in contact. The extreme looseness of the submucous tissue allows the membrane to close over the tube without force. The raw surface left by raising the two quadrangular flaps of mucous membrane is covered in by drawing the edges on each side of the artificial channel over the latter and uniting them by suture. The stomach wound is then closed with a Czerny-Lembert suture; the edge of the orifice from which the tube projects is stitched to the skin. Finally, the wound in the abdominal wall is closed, excepting the point occupied by the tube. As yet, this operation has not been tried on the human.

#### TREATMENT OF FRACTURES OF THE JOINTS.

ROTTER (*Medicinisch-Chirurgisches Centralblatt*, No. 17, 1894) takes as typical joint-fracture those injuries, due to indirect force, so frequently observed about the knee and ankle, in which there is not only injury of the bone, but the ligaments are extensively torn and there is more or less displacement. The most important therapeutic means for combating these injuries are immobilization, massage, and the early institution of passive motion. The proper combination of these agencies occasions quick healing and the most complete functional restoration. Immobilization is the first treatment

to be instituted, not only because of the relief it gives to pain, but because by this means the lacerated parts are held in their proper position until a certain amount of repair has taken place and they have no spontaneous tendency to drop out of position. If there be displacement, this must be forcibly corrected at once. In case of fracture about the ankle-joint, the knee-joint should be bent to relax the calf muscles, and the foot should be held at right angles to the long axis of the leg. Before application of the dressing, thorough examination must be made to determine that the foot is neither displaced antero-posteriorly nor laterally. Immobilizing apparatus should be worn for eight days. Complete circular plaster bandage should never be used unless the patient is constantly under observation. Even when the patient is carefully watched, the trouble of removing this bandage is so great that it constitutes a serious disadvantage. The safer are the ordinary splints or fracture-box. These allow of the application of the ice-pack upon the seat of swelling. After eight days massage and passive motion are instituted. A plaster bandage is then applied for eight days, the foot and ankle being held in normal position. Sometimes anæsthesia is required when involuntary muscular contractures interfere with the proper position of the foot and ankle; the bandage is then removed and massage and passive motion is practised. Active movement should not be attempted before the fifth week.

#### TREATMENT OF TUBERCULOSIS OF THE TONSIL.

TUSSAUD (*Lyon Médical*, April 22, 1894), on the basis of three cases of tuberculosis of the tonsils, concludes that abuse of alcohol and tobacco are predisposing factors in the development of this affection. As treatment he prefers the galvano-cautery, carrying this not only through the diseased tissues, but into the surrounding comparatively healthy tissue, thus preventing absorption by forming a barrier of sclerotic tissue. In two of the reported cases the local lesions were cured, but, owing to persistence in bad habits, the patients ultimately perished of general tuberculosis.

#### TREATMENT OF AURAL VERTIGO.

MACKENZIE (*British Medical Journal*, No. 1740, 1894), after a discussion of the lesions, the diagnosis, and the causes of aural vertigo, holds that the prognosis is unfavorable so far

as recurrences are concerned, unless the condition is due to a foreign body.

The treatment of an acute attack requires that the patient should be put in a recumbent position so long as the vertigo is increased by standing up. The excitability of the nervous centres is subdued by bromide of potassium given in moderate doses. In gouty cases, bromide of lithium, also the salts of potassium, colchicum, and salicylate of sodium are often of service, especially when preceded by a mercurial purge. Counter-irritation, in the form of a small blister behind the ear, is sometimes of benefit. Any local disorders of the middle or external ear should receive attention. During the intervals between paroxysms, quinine, 3 or 4 grains three times a day, and in some cases double this dose, is of service. Salicylate of sodium appears to do good; pilocarpine is recommended given hypodermically, beginning with 3-minim doses of four-per-cent. solution every day, and increasing the dose to  $\frac{1}{16}$ ,  $\frac{1}{8}$ , or even  $\frac{1}{4}$  if the drug is well borne. The arterial tension should be well observed. For the purpose of keeping this down, mercury is particularly serviceable, an occasional blue pill being given once or twice a week, or, in place of this, calomel may be used, 3 to 5 grains, to be taken whenever there are premonitory symptoms, such as increased tinnitus, fulness in the head, or headache.

#### FRACTURED PENIS.

MENDE (quoted in *Monatsshefte f. Prakt. Derm.*, Bd. xviii., No. 9) reports a case of fractured penis. The patient, aged forty, ran with erect penis against the back of a chair. He experienced severe pain. Catheterization the following day drew blood only. The penis was greatly swollen, bluish-black towards the symphysis, and curved with the convexity below. Fluctuation was felt behind the glans where the bending was most marked. Repeated efforts at catheterization failed. The boutonnière operation was performed and a Nélaton catheter passed through the peritoneal opening. Some days later the penis was opened freely on the base, the torn urethra was sutured, and the patient recovered, with complete restoration of function.

#### CONGENITAL HYDROCELE OF THE NECK CURED BY DRAINAGE AND COMPRESSION.

DICKINSON (*British Medical Journal*, May 12, 1894) reports a case of congenital hydro-

cele of the neck cured by drainage and compression. The patient was three years old. At birth the hydrocele was noticed and gradually increased until it extended from the sternal line of the left clavicle in front to the middle line behind, and entirely filled the sulcus between the neck and the shoulder. By means of a trocar and canula eight ounces of greenish-brown albuminous fluid were withdrawn; a small incision then allowed of digital exploration; the cyst was drained by means of several strands of fishing-gut. The discharge became muco-purulent, owing, no doubt, to sepsis; the temperature ran up, the seton cut out, and the wound continued to discharge more or less freely till it healed, five weeks after the operation.

#### PREVENTION OF CATHETERIZATION CYSTITIS.

GROSGLICK (*Monat. f. Prak. Derm.*, Bd. xiii., No. 9) holds that since the urethra contains many micro-organisms which, in spite of all antiseptic precautions, may be pushed into the bladder by a clean catheter, and since disinfection of the urethra is neither possible by local washings nor by the administration of antiseptics by the mouth, and since urinary retention offers the most favorable culture-field, this dangerous complication is best avoided by the most scrupulous cleanliness, by soft rather than metallic instruments, since there is less insult to the mucous membrane by the slow progressive evacuation of the urine even in cases of retention of short standing, since a sudden evacuation occasions bladder hyperæmia, which is most favorable to the growth of micro-organisms. Catheterization should be repeated every six hours until the bladder can be evacuated spontaneously. If for any reason periodic catheterization is not possible, a permanent catheter should be employed.

#### PERFORATION OF A CHRONIC ULCER OF THE DUODENUM SUCCESSFULLY TREATED BY EXCISION.

DEAN (*British Medical Journal*, May 12, 1894) reports a case successfully treated by excision. The patient, a woman of twenty-seven, entered the hospital complaining of intense abdominal pain. She vomited frequently; she had a feeble pulse of 120; a rapid and small respiration; her belly was moderately tympanitic. Diagnosis of acute general peritonitis was made and operation performed. On opening the peritoneal cavity

purulent fluid escaped. In the region of the gall-bladder some flakes of lymph were found, in the centre of which gas bubbled, forming a froth. This gas was found to come from the duodenum, perforation being there situated three-quarters of an inch from the pylorus. Around the perforation a distinct induration could be felt. This indurated area was excised, and the elliptical opening thus made into the duodenum was sewed up by silk sutures, according to Lembert's method. The peritoneal cavity was washed out with warm weak boracic lotion, well sponged, and the wound closed. The patient recovered without incident, and was up and about three weeks after operation. Two weeks later she was attacked by acute intestinal obstruction due to a band. A second operation was performed, in which she perished. On post-mortem examination two perforations were found, each the seat of ulceration, above the seat of constriction for which the last operation was performed.

#### ABDOMINAL HYSTERECTOMY IN WHICH THE URETER WAS RESECTED AND IMPLANTED INTO THE BLADDER.

PENROSE (*Kansas City Medical Index*, No. 5, 1894) reports the following case of immediate implantation into the bladder of a ureter which had been divided during a coeliotomy.

A white woman, aged forty years, had a scirrhus cancer of the cervix uteri. Growth extended as high as the internal os, and infiltrated the left broad ligament, in a dense hard mass, to a distance of about one inch from the cervix. There was no involvement of the vagina. No symptoms of ureter obstruction.

Coeliotomy performed July, 1893. It was found that the left ureter passed directly through the hard mass in the left broad ligament, and in order to remove completely all diseased tissue, it was necessary to excise about one inch of the ureter,—the portion involved in the broad ligament.

After the uterus had been cut away at the vaginal junction, the distal end of the ureter was ligated with silk, the vagina closed, the peritoneum sutured over the seat of operation as much as possible, and the proximal portion of the ureter then implanted into the body of the bladder. The operation was similar to that used by Van Hook for uniting a ureter after complete transverse division, by lateral implantation of the proximal into the distal portion (*Journal American Medical Association*, March 4, 1893). An incision was made antero-posteriorly in the body of the bladder

somewhat less than half an inch in length. A needle armed with fine silk was passed through the bladder-wall from without in, at a point about a third of an inch from the edge of the incision on the right, and brought out through the incision. It was then carried through the right wall of the ureter close to the extremity, carried back through the incision in the bladder, and passed through the bladder-wall from within out, close to its point of entrance. A similar suture was passed on the left side of the incision in the bladder and through the left side of the wall of the divided ureter. Traction on these sutures dragged the ureter into the bladder, and when tied they held it in this position.

The loose peritoneum, which formed a partial investment to the ureter, was drawn down and sutured to the peritoneum of the bladder by a continuous silk suture around the line of union of the ureter with the bladder; the abdomen was closed without drain. A soft-rubber catheter was introduced through the urethra and retained for three days. The patient made an unusually easy recovery.

A recently-reported case of Dr. H. A. Kelly, where a divided ureter was immediately united by lateral implantation of the proximal into the distal portion, and the case just reported, go to show that the advice of our surgical textbooks should be modified, and that, if the patient is able to endure a slightly-prolonged operation, and the anatomical conditions are suitable, it is better immediately to implant the proximal portion of the ureter into the distal portion, or into the bladder.

#### HYSTEROPEXY IN CASES OF INTRAC- TABLE RETROFLEXION.

BRAITHWAITE (*British Medical Journal*, May 19, 1894) suggests the following modification of the mode of performing the operation of ventro-fixation of the uterus in cases of intrac-table retroflexion, which he supports with ten cases operated upon by the method given below.

The central incision in the abdominal wall is made, as usual, low down, and with its lower end not more than an inch, or even less, above the pubes; but he cuts only through the peritoneum itself in the upper half of the incision; in the lower half it is left intact, with as much fascia and cellular tissue as possible, the muscles, however, being drawn aside. Two fingers of the left hand are then passed in and the uterus pulled up to, and held firmly in contact with, the uncut peritoneum exposed in the

lower half of the wound. The fundus is then just visible above the edge of the peritoneum. The anterior surface of the uterus is now fastened to the peritoneum by silkworm-gut sutures, nearly as done by Drs. Napier and Schacht.

This plan of operating has several advantages. Two sutures can be placed from above downward at the extreme edges of the anterior surface of the uterus, in addition to the usual transverse ones. This insures a more complete and extensive coaptation of the peritoneum. It also does away with the objection raised by H. A. Kelly, that the adhesion produced elongates, so that soon the uterus is merely suspended by a band.

#### TUBERCULOSIS OF THE BLADDER.

At a meeting of the Brooklyn Surgical Society, November 16, 1893, DR. PILCHER (*Brooklyn Medical Journal*, vol. viii., No. 6) presented the following interesting case:

A man some twenty-five years of age applied to the Methodist Hospital for relief from chronic cystitis. He had some cough and emaciation, but the severity of his bladder-troubles exceeded all else. Symptoms had progressed for a year. For a period of ten days he was kept under observation at the hospital, during which time, from every half-hour to one hour, he would urinate with great pain, the urine containing characteristic deposits of cystitis. A cystoscopic examination was made, but owing to the rapid supervention of hemorrhage it was impossible to prolong examination to any great extent or derive any special information. Upon rectal examination, a thickened condition of the vesiculæ seminales was distinctly defined and a special nodular deposit in the right vesicle was evident to the touch. The usual treatment for cystitis was carried out during his stay, including systematic washings of the bladder by mild antiseptic agents, but without benefit. Examinations for tubercle-bacilli in the urinary deposits met with negative results. However, notwithstanding the failure to find bacilli, the pulmonary trouble lent force to the belief of tuberculosis of the bladder.

He was therefore subjected to suprapubic cystotomy, in which operation Dr. Bristow's method of dilating the bladder with air instead of water was employed. The appearance of the bladder shown would indicate that had water been used for dilatation it would have resulted in extravasation of its contents, on account of the existence of certain diverticula with very thin walls; also the bladder was like

a flaccid bag, having very little expulsive power and not contracting when it was opened.

Section disclosed a small abscess cavity in the supravescical space, just behind the symphysis. This was opened and evacuated; then, the incision being continued, the bladder was opened and its contents permitted to escape. The weak condition of the patient forbade further surgical interference. The granular condition of the mucosa was noted. The patient made a good recovery. The iodoform tampon applied at the time of operation was withdrawn on the third day, and from that time until the time of his death, some six weeks later, his bladder-symptoms were greatly relieved. Drainage through the suprapubic opening was sufficient to enable the bladder to be readily relieved. A portion of the time a double drainage-tube was kept in the opening, and at other times a simple iodoform gauze mesh was placed in the opening. The bladder was washed out daily; and at varying intervals, averaging twice a week, half an ounce of a ten-per-cent. iodoform emulsion was injected into the bladder and permitted to remain.

Post-mortem examination revealed diffuse tuberculosis of both lungs, with advanced destruction of portions of them, with diffuse tubercular deposits in the small intestines, and a granular condition of the mucous membrane of the bladder throughout its whole extent. This was less marked in the mucous surface of the trigone, the smooth reddish surface of which was suggestive of recently-healed ulceration. The ureters were free from disease, nor was the kidney involved. A curious feature was, that on either side of the bladder there was an attachment of a loop of small intestine, and by long traction the inflammatory adhesion has been elongated so as to form a band and a diverticulum from the bladder on each side.

Pilcher also cites the case of a young man, aged twenty-one, with tubercular antecedents, suffering from bladder-symptoms indicating the presence of profound disturbance, on whom suprapubic cystotomy was done by him, and a patch about the size of a half-dollar, at the lower lateral wall of the bladder, exposed, presenting a velvety surface deeply congested. Bacilli were absent from the discharges in this case as well. For several months drainage through the suprapubic opening was continued. Finally, the fistula was allowed to close, all his symptoms subsided, and up to this report (nearly two years) he remains well.

In still another case the author had recourse to the above means with similar satisfactory results.

In discussing the paper, Dr. Wood said that a young woman under his care, giving symptoms indicating bladder tuberculosis, was subjected to suprapubic cystotomy some three years ago; a small ulceration was found, scraped, and treated with iodoform. The symptoms subsided and the suprapubic wound was allowed to close. A few months afterwards she suffered from a return of symptoms. The bladder was reopened and the ulcerated spot again recognized in the same position, a little larger. It was treated as before, with the addition of lactic acid. A year later no recurrence was noted.

#### *EFFECTS OF ERYSIPELAS ON EPITHELIAL CANCER.*

COLLINS (*Kansas City Medical Index*, No. 5, 1894) reports the following case:

Eighteen months ago his attention was called by a patient to an ulcer nearly opposite the ear on his right cheek. This ulcer was one and a half inches in longest diameter, one inch in the shortest, forming an oval with irregular edges. The discharge was slightly purulent, tinged with blood. The granulations were soft and bled on the slightest touch.

The patient stated that twenty years ago there appeared at this point a small elevation, which frequently formed a scab, which every ten or twelve days would fall off and then reform, giving but little trouble and receiving but little treatment.

Nineteen years ago he was treated for a time with ointments and lotions, also some medicine was administered without special benefit. He was then assured that this was skin cancer and incurable. The ulcer gradually increased in size and depth. Some benefit was derived from a lotion of zinc sulphate and salt, dissolved in water to make a mild astringent solution. The ulceration, however, continued giving considerable pain, but much annoyance by its presence.

On November 12 he suffered from an attack of erysipelas of the face. This ran no unusual course, spreading rapidly from the tip of the nose, over the scalp, to the nape of the neck. The external dressing was of ichthyol and lanolin, which seemed to give relief and comfort.

As the erysipelas faded out and desquamations followed, the ulcer seemed to assume a more healthy appearance. Granulations of a normal character developed, and in about two weeks the ulcer was entirely healed. The cicatrix on March 1 is slightly indurated, but smooth and firm, presenting the appearance of normal cicatricial tissue.

## INGROWING TOE-NAIL.

TOUSEY (*New York Medical Journal*, May 19, 1894) has modified Cotting's operation by applying Thiersch's skin-grafting on the second day, shortening the time of healing by a week. Cotting's operation consists in excising the overlapping soft tissues; this can be performed under cocaine. The method of performing this operation is as follows: The point of the scalpel, with its edge held vertically forward, is placed at the side of the nail close to the matrix, and is pushed vertically through the toe close to the nail. The knife is then carried forward, converting the part of the toe external to the nail into a flap. The edge of the knife is then turned backward, and this flap is entirely severed by an oblique cut outward and backward. The nail is not cut at all and the matrix is not even exposed, but the side of the toe is hollowed out so that the side of the nail projects at all points beyond the flesh. The area thus denuded is about the size of a silver quarter of a dollar. The dressing consists of simple gauze for a week, then gauze moistened with balsam of Peru, the dressings being changed every three days. Complete cicatrization takes at least three weeks, and the surface requires a protective dressing for a week or two beyond that.

Tousey, to hasten cicatrization, applied iodoform gauze as the first dressing; two days later he removed this by soaking in sterilized salt solution, thus occasioning no bleeding. A graft sufficiently large to cover the entire raw surface was taken from either the leg or the arm. Over this graft rubber tissue and gauze moistened with sterilized salt solution (0.6 per cent.) was applied, and was changed every other day for a week, at the end of which time the surface was found healed.

## APPLICATION FOR BURNS.

The following is UNNA's prescription for burns (*Medical Press and Circular*, May 23, 1894):

R Lanolini, parts x;  
Adipis benzoati, parts xx;  
Aq. calcis, parts xxx.

## EPIDIDYMITIS.

ROLLET (*Medical Press and Circular*, May 23, 1894) holds that when epididymitis occurs as a complication of gonorrhoea, irrigation of the entire urethra should not be intermitted, since otherwise there is danger of the second

testicle becoming involved. The best treatment, in his opinion, is salicylate of sodium, a drachm and a half daily, or tincture of pulsatilla, 10 drops three times daily. The action of this agent is not as constant as that first named. Refrigeration is the best means of allaying pain; this is produced either by application of ice to the inflamed parts or by the spray of chloride of ethyl. The latter must be used with caution, on account of the sensitiveness of skin of scrotum. Reclus recommends the application of compresses of warm water. Rollet has been using for some time back, with considerable satisfaction, guaiacol, which he applies by means of a brush over the surface daily; not more than 1 gramme, or 20 drops, is used each time. The pain produced by the agent is slight and of short duration, while that appertaining to the malady disappears in about two hours, and the temperature falls.

## ARTIFICIAL HYPERÆMIA IN THE TREATMENT OF DELAYED UNION.

BUECHNER (*Journal of the American Medical Association*, May 26, 1894) calls attention to artificial hyperæmia in the treatment of delayed union,—a comparatively unknown, but very efficient, method.

Helferich proves, by citing cases where an increased blood-supply, caused by some pathologic condition, produces a thickening of bone in adults and a lengthening, or thickening, or both, in children, that hyperæmia plays a prominent part in the formation of new bone. It will not, however, cause the production of callus, but will only increase it when started by some other natural or artificial means.

To illustrate this method, Helferich takes a fracture of the humerus for an example. He first applies a flannel bandage from the fingers to a point about an inch and a half below the fracture; at the same distance (an inch and a half) above the fracture he applies a piece of rubber bandage or tubing tightly enough to retard the return of the venous blood, but not to interfere with the arterial circulation. This produces a marked congestion in the parts surrounding the fracture which are left uncovered by the bandages. At first the constriction is only allowed to remain a short time, but the duration of its application is rapidly increased until it is soon left on day and night. The writer has found its almost continuous application for a period of ten days sufficient in the cases in which it has effected a cure.

During the use of this method the fracture

should be properly immobilized. In the case of the upper extremity this is easily accomplished by the use of splints. In fractures of the leg a plaster-of-Paris dressing is employed, and the constrictor applied at its upper margin. To admit of the swelling and congestion at the desired point, the plaster dressing is applied quite snugly, the part where the congestion is desired being either heavily padded with cotton or large fenestræ being cut in the dressing. In fractures of the femur the Buck extension is used, the flannel bandage and constrictor being applied as in the case of the humerus.

This method should not be used where there is any tendency to a varicose condition of the veins. Helferich says it will not produce this condition in normal vessels. The same writer reports eight cases "in which, at the time a fracture is usually healed, there was very little or no callus." Six were fractures of the leg and two of the thigh. By the use of this method alone he accomplished a cure in each case in a few weeks. He also reports four cases—three of the leg and one of the forearm—in which it was employed subsequent to the nailing together of the fragments. All resulted in cures.

These cases indicate that in constriction and the resulting hyperæmia we have a valuable adjunct to the better-known methods of treatment in delayed union and pseudarthrosis.

#### BASSINI'S OPERATION.

FOWLER (*Brooklyn Medical Journal*, No. 6, vol. viii.) states that the object of Bassini's operation is to restore the normal location and tension of the displaced and relaxed structures. He accomplishes this in the following manner: The sac, together with the fascia lata and pectineal fascia, is exposed by an incision, which is placed parallel with and just below Poupart's ligament. The sac and its neck are isolated by blunt dissection to a point beyond the crest of the pubes. The sac is opened and its contents caught by a clamp to prevent untwisting, a ligature passed through the twisted portion and the neck securely ligated. The portion of the sac beyond the ligature is now cut away and the stump replaced, so as to expose the parts forming the canal and the oval ring. The latter is now closed as follows: The first suture is applied close to the spine of the pubes and passes through Poupart's ligament, after which the latter is somewhat elevated, and the suture is made to include the pectineal fascia at the level of the pelvic crest. The following sutures

are placed in a similar manner, approaching the crural vein; the fourth includes the falciform fold of the fascia lata and the pectineal fascia. None of the sutures are tied until all are placed in position. In securing the sutures, Bassini ties first those placed above. A C-shaped suture line arises in consequence of the tightening of the first three sutures, which is considerably depressed at its middle. The skin is now sutured separately. The operation occupies from fifteen to thirty minutes. Patients are allowed up after ten days; no truss worn.

Bassini's experience with this method includes fifty-four operations in fifty-one individuals (forty women and eleven men); the youngest of these was seventeen and the oldest seventy. Recovery took place in all cases without complication. Eight left the hospital after nine days, twelve after ten days, five after eleven days, and four after twelve days. The remaining twenty-one left the hospital after from thirteen to twenty days. None of the patients have since worn a truss and all are able to work. The time of observation extends over periods varying from three to nine years in twenty-seven cases; between two and three years in fourteen cases; the remainder for less than two years. In at least forty-one cases the cure remained permanent for periods extending from two to nine years.

#### STERILIZED CATGUT IN A CONVENIENT AND PORTABLE FORM.\*

KILIANI (*Medical Record*, May 19, 1894) advises that catgut should be sterilized as follows:

Dry catgut, not kept in oil, is put in absolute alcohol for twenty-four hours to remove all moisture, is cut off in pieces of two and three yards' length, one of which is rolled on a glass rod and then put in a glass tube open at one end and with a little hole in the other, through which a short end of catgut is pulled. The glass rod is removed and the roll of catgut is in the glass tube. This tube, with its contents, is put in a second glass tube a little wider and longer, with one end open. Then the tube is put in a dry hot-air sterilizing apparatus, the temperature of which is brought within one hour up to 176° F. This is to cause evaporation of the alcohol and water. The open end is then closed by melting the glass, and the hermetically-sealed tube is put again into the sterilizing oven, the temperature of which is brought within one hour up to the course of two hours more to 140° C. (284° F.), which is kept up for a whole hour. Another hour is consumed in letting the temperature gradually sink

again; then the outer tube is scratched with a file and it is ready for use. Immediately before using it, the outer tube is broken and the inner tube, with its contents, put for two minutes into the solution in which the instruments are lying.

This is Reverdin's method, slightly modified as to the method in which the catgut is stored.

#### TREATMENT OF DIPHTHERIA.

OLSON (quoted by the *Universal Medical Journal*, June, 1894) orders the following dissolved in spray in diphtheria:

- R Oil of eucalyptus,  $\text{zii}$ ;  
Benzoate of sodium,  $\text{zi}$ ;  
Bicarbonate of sodium,  $\text{zii}$ ;  
Glycerin,  $\text{zii}$ ;  
Lime-water, enough for a quart.

Sig.—Spray on the membranes for from three to five minutes every half-hour.

#### SUCCESSFUL LIGATURE OF COMMON CAROTID AFTER SECONDARY HEMORRHAGE FROM THE INTERNAL MAXILLARY.

JONES (*British Medical Journal*, June 16, 1894), in a case under his charge, which had been operated on for an epithelioma so extensive as to require the removal of the left half of the axilla, reports successful ligature of common carotid after secondary hemorrhage from the internal maxillary. Secondary hemorrhage occurred some two weeks after operation. He ligated the common carotid artery, then injected twenty ounces of warm saline solution into the median cephalic vein. The patient recovered.

#### TREATMENT OF PHARYNGEAL DIPHTHERIA.

HAMILTON, in cases of pharyngeal diphtheria, advises the following:

- R Mercury biniodide, gr. ii;  
Oil of peppermint,  $\text{mii}$ ;  
Sugar,  $\text{zi}$ . M.

Sig.—Place from 5 to 10 grains in powder every hour or two on the tongue, not giving any water for a few minutes afterwards.

The author advises that if laryngeal or tracheo-laryngeal symptoms develop, a quart of unslaked lime should be placed in a vessel of appropriate size and half an ounce of turpentine poured on it, then enough boiling water to completely cover the lime; the vessel should

be placed under a cotton sheet, thrown also over the head of the nurse and affected child. A cloud of vapor will be emitted for ten minutes at each sitting, which can be repeated hourly, if required, for the paroxysms of difficult breathing.—*Universal Medical Journal*, June, 1894.

#### FRACTURE OF DISLOCATED HUMERUS.

MCBURNIE (*Annals of Surgery*, April, 1894) was called to see a patient who, nine days before his visit, had broken his humerus and dislocated the head of the bone. The upper fragment was exposed and drilled and a strong hook screwed in it, thus allowing direct traction and after some difficulty replacement of the bone. The patient recovered with a useful arm.

#### EXTIRPATION OF THE LEFT LOBE OF THE LIVER.

TRICOMI (*Rev. de Chir.*, 1894, quoted by *British Medical Journal*, June 16, 1894) was consulted by a young man suffering from tumor of the liver the size of a fist. Around the base of the latter an elastic ligature was secured. The hepatic layer of perineum was dissected up around this ligature and stitched to the parietal. After two weeks the ligature came away and the tumor still remained fixed. An attempt to remove it by wire ligature was no more successful, nor did the thermo-cautery prove any more satisfactory, since it did not arrest bleeding. Some days later the growth was cut away and bleeding was stopped by the thermo-cautery and iron solution. In about two months the wound was quite healed. In this relation Ceccherelli and Bianchi's method of arresting hemorrhage from the liver is of interest. This consists of the application of a quilled suture. The portion of the liver which it is proposed to excise is circumscribed by two strips of whalebone, each perforated from end to end by several holes. A long needle armed with a double thread is passed through the hole at one end of one strip of whalebone, then through the liver-structure, and finally through the hole at the corresponding end of the second strip. Other ligatures are passed through all the other holes in both strips and through the intervening portions of liver. One of the ends of the first ligature is tied to the cut end on the opposite side, and then all the ends are closely tied together along the whole length of one strip of whalebone and afterwards along the second strip. In this way the interposed liver-tissue is closely constricted and gradually crushed.

All the ligatures having been secured, the liver may be freely incised without dread of hemorrhage. In order to avoid leaving a large raw surface exposed, and to guard against secondary hemorrhage, it is recommended that the free ends of the ligatures attached to one strip of whalebone be passed across the divided pedicle and tied to those of the other strip. In this way the hepatic tissue may be compressed at the seat of section.

#### JANET'S METHOD OF TREATING GONORRHOEA.

ANDREY (*Monat. f. Prak. Derm.*, Bd. xviii., No. 11) writes enthusiastically of Janet's method of treating gonorrhoea. This consists in irrigation of the entire urethra with solutions of permanganate of potassium varying in strength. The meatus, glans, and foreskin are first carefully cleansed. All these surfaces are then powdered with a mixture of talc and boric acid. No internal treatment is used at all; even alcohol need not be absolutely forbidden. The patient is warned that the treatment is somewhat painful. Complications are conspicuous by their absence. The armamentarium consists of a vessel holding from three to four pints of liquid, to which is attached a rubber tube two and a half yards long. A couple of glass nozzles with round points are kept in antiseptic solution. These are conical, and so made that they can be passed into the urethra at least two-fifths of an inch. One of these is attached to the end of a rubber tube. The reservoir is so arranged that it can be hoisted to a height sufficient to overcome the resistance of the compressor urethræ muscle, —usually three feet; exceptionally six or seven feet are required. The patient first empties his bladder, then lies down on his back, and after cleansing of the external parts, introduces the glass canula, which is attached to the tube of the reservoir, and turns on the stream. After a few ounces have passed into the urethra and out again by the sides of the canula, the meatus is clasped closely around the latter, and, the reservoir is watched to see when the liquid begins to flow into the bladder. Sometimes this lasts a few seconds; occasionally, some time elapses before this resistance is overcome. The stream is interrupted at intervals by pressure on the rubber tube, thus repeatedly distending the anterior urethra. Sometimes the resistance of the sphincter is not overcome by the first treatment, practice being necessary on the part of the patient. He is instructed to make an effort at urination. This facilitates

deep irrigation. When the patient experiences a strong desire to urinate this indicates that the bladder is full. It is better to inject not more than a half-pint to one pint. The glass tube is withdrawn, and the patient is instructed to urinate, occasionally stopping the stream by putting the finger over the meatus, this action distending the urethra. The bladder is distended once again after this and is again emptied. The strength of the solution varies from 1 to 1000 to 1 to 6000 of permanganate of potassium. The stream should be repeated every twenty-four hours. In very recent cases twice daily; in old cases these daily treatments should suffice to bring about a cure. When the patient presents himself in the florid stage, eighteen to twenty days is usually necessary. These washings are only stopped when the gonococcus is no longer found in the discharge. As long as the latter is white and thick it probably contains these micro-organisms. Immediately after the injection there is swelling of the entire penis, including the foreskin, and an abundant reddish serous discharge. Urination is painful. This continues for four or five hours, and is a favorable sign.

Contraindications to this treatment are the presence of cystitis or follicular urethritis. Epididymitis is a distinct indication for its employment. The report states that eighty per cent. of his cases were well in ten days; fifteen per cent. required longer treatment; five per cent. left his hospital uncured. The results are placed on very recent and very old gonorrhoeas. Usually, after this there is still a discharge, which lasts for four or five weeks and then disappears spontaneously. Eight or ten days after treatment coitus is allowed, the patient being instructed to wear a condom to avoid reinfection.

#### SURGICAL INTERVENTION IN INJURIES OF THE SPINAL CORD.

BEREZKINE (*La Tribune Médicale*, June 7, 1894) communicates a case of successful intervention for the relief of symptoms dependent upon traumatism of the cord. A young man shot himself with a revolver in the præcordial region. There resulted complete paraplegia, retention of urine and feces, anæsthesia in the lower part of the belly and the legs, the wound of entrance was about the level of the sixth rib, about an inch within the left nipple-line. The eleventh dorsal vertebra was painful on pressure. A longitudinal incision was made along the spinal processes of the eleventh and twelfth dorsal vertebrae and of the first lumbar. Every-

thing was found normal, the wound was closed. Ten day's later, as there was no change in the patient's condition, laminectomy of the three lower dorsal and first lumbar vetebræ was performed. When the dura mater was incised and the cord pushed to the right, a foreign body was felt in the body of the eleventh vertebra; this was extracted by means of a longitudinal incision of the cord and dura mater. Four days after operation micturition and defecation were normal. The patient regained the power of motion and anæsthesia was rapidly disappearing.

#### *PAINFUL CYSTITIS TREATED BY DRAINAGE OF THE BLADDER.*

LUMEAU (*Anal. de la Polioclinique*, No. 20, 1894) holds that suprapubic drainage is always to be preferred in the treatment of painful cystitis, since thus is allowed at the time of operation a thorough inspection of the interior of the bladder and the removal of tumor, stones, or other mechanical causes keeping up irritation. In tubercular cases especially this method should be employed, since the perineal route usually aggravates the trouble.

#### *LACTATE OF COCAINE IN CYSTITIS.*

WITZACK (cited by the *Journ. de Méd. de Paris*, No. 22, 14 anée) employs the following formula in the treatment of tubercular cystitis, holding that the lactate of cocaine greatly lessens or entirely relieves the pain incident to the employment of the lactic acid:

R Lactate of cocaine, 2 parts;  
Lactic acid and distilled water, 10 parts.

After having emptied and washed out the bladder, about 15 drops of the solution are applied to the ulcerated spot.

#### *WOOL FATS.*

IHLE, writing upon various wool fats,—namely, lanolin, adeps lanæ, œsypus,—holds that the latter is better borne in the great majority of cases than any other fatty preparation, not excepting resorcin, since it never dries and does not decompose. The paste he employs is made up of equal parts of œsypus, zinc oxide, and olive oil. When adeps lanæ is employed, the most suitable combination is as follows:

R Adeps lanæ, 15 parts;  
Zinc oxide, 10 parts;  
Olive oil, 5 parts.

Adeps lanæ is admirably adapted for the

making of mercurial ointment, according to the following formula:

R Hydrarg., 20 parts;  
Adeps lanæ, 50 parts;  
Benzoat., 10 parts;  
Ol. bergamot, 3 parts.

In the treatment of seborrhœa the author employs the following prescription:

R Resorcin, 5 parts;  
Ol. ricini, 15 parts;  
Balsam of Peru, 3 parts;  
Spiritus vini, 77 parts.

This is used in the morning, and in the evening there is rubbed into the head,—

R Adeps lanæ, 40 parts;  
Ol. amygdal.,  
Sulph. præcipitat., of each, 5 parts;  
Oil of rose, 1 drop.

—*Anal. de la Polioclinique*, No. 20, 1894.

#### *THE ANTISEPTIC VALUE OF ICHTHYOL.*

ABEL (quoted by *Deut. Med. Zeit.*, June, 1894), as a result of bacteriological research, found that preparations of ichthyol in weak solution quickly killed pyogenic streptococci, but the staphylococci and certain bacilli resist its toxic action. He advises that the drug should be kept pure or in fifty-per-cent. solution, since in weaker preparations the staphylococci of pus may remain alive for a long time, and thus such dilutions may actually infect a previous sterile wound. All weaker solutions should be sterilized by boiling before applying to raw surfaces.

#### *EIGHT HUNDRED AND FIFTY-TWO OPERATIONS FOR STONE IN THE BLADDER.*

Since 1877 (*British Medical Journal*, June 16, 1894), FREYER has operated on eight hundred and fifty-two cases of stone in the bladder,—two hundred and forty-five by perineal lithotomy, six by suprapubic lithotomy, three by rapid dilatation of the urethra in females, and five hundred and ninety-eight by litholapaxy. Every patient suffering from stone was operated on, no matter in what condition he presented himself; nor was any patient lost sight of until a cure had been effected. In the litholapaxy series a full fenestrated lithotrite was used to avoid the danger of *débris* becoming impacted. Bigelow's simplified aspirator is the one employed. The canulæ are only slightly curved, with the eye on the concave surface close to the end. They range from No. 6 to

18 English. Of the five hundred and ninety-eight cases of litholapaxy, there were four hundred and thirty-four adults and one hundred and sixty-four children. The adults varied in age from sixteen to ninety-six years, the average being forty-eight and a quarter years; the children from one and one-half to under sixteen years, the average being just seven years, three of them twice. Indeed, it may be stated that recurrence is as frequent after lithotomy as after litholapaxy. Great stress is laid on completing the operation in the first sitting. In five hundred and ninety operations in only eight was it necessary to have recourse to a second sitting, and in only two cases designedly. The time occupied by the operation varied from a couple of minutes to two hours. If possible, the stone should be entirely crushed upon the first introduction of the lithotrite. Patients were usually anæsthetized, but lately the operator has been in the habit of operating without anæsthesia when the urethra is capacious, or by producing local anæsthesia with cocaine. Where stricture complicated, this was at once treated either by rapid dilatation or by cutting. Moderate enlargement of the prostate was no serious impediment to the operation. Very great enlargement of course requires suprapubic operation. In these cases of hypertrophied prostate there is always much bleeding, and this renders complete evacuation more difficult, since the fragments of calculus are liable to become embedded in clots of blood, which have to be broken up by the aspirator and then removed with the entangled *débris* of stone. Where cysts complicated the disorder no special treatment was adopted. Kidney-disease, in all its stages, was frequently present, but, so far as the performance of litholapaxy goes, the author never desists, no matter what the state of the kidneys may be. Among the five hundred and ninety-eight litholapaxy operations there were thirteen females. One stone weighed over six and a quarter ounces; it was uric acid and unusually hard. Encysted calculi were also attacked by the lithotrite, since these stones usually lie in wide-mouthed pouches. When possible, the stone was generally withdrawn into the wider cavity of the bladder. If this was not possible, it was crushed *in situ*. The diagnosis, especially in cases of small stones, was established by means of an aspirator and canula. When the calculi are small, most careful sounding may fail to discover them. If, however, a full-sized canula is employed, the aspirator applied, and the process of pumping in and exhausting water, moving the eye of the canula about in

the bladder in various directions, and inserting it into pouches, should such exist, should a small stone be present, it will be carried with force against the eye of the canula by the outward stream, and a ringing click announces its existence. The reporter was in the habit of always performing lithotomy in children, having had a record of one hundred and ninety-seven cases, with only one death. Since 1885 he has performed litholapaxy one hundred and fifty-eight times, with two deaths. His first one hundred and nineteen cases were all successful; he then lost two cases consecutively. Among the five hundred and ninety-eight litholapaxy operations there were eleven deaths: nine among four hundred and twenty-six operations on adults, and two among one hundred and sixty-four on children; five cases perished of exhaustion, two of peritonitis, one of acute pyæmia, one of acute nephritis, and two of acute cystitis.

The eleven deaths in five hundred and ninety-eight litholapaxy operations—namely, four hundred and thirty-four adults, with nine deaths, and one hundred and sixty-four children, with two deaths—give a mortality of 1.84 per cent. on the whole, or about two per cent. in adults and 1.22 per cent. in children. There were two hundred and fifty-four lithotomies in his practice, with eleven deaths,—namely, fifty-four adults, with ten deaths, and two hundred children, with one death, giving a mortality of four and one-third per cent. on the whole, or eighteen and one-half per cent. in the adult, with one-half per cent. in children.

Freyer announces that he is an entire convert to the operation of litholapaxy in nearly all cases. Of his last three hundred cases of stone he was forced to resort to the cutting operation in six instances. He therefore strongly opposes Sir Henry Thompson's adage to the effect that suprapubic lithotomy is indicated in cases of large calculi.

#### CONSERVATIVE TREATMENT OF FEMALE PELVIC ORGANS.

GOODELL (*University Medical Magazine*, July, 1894), after considering the above subject at length, arrives at the conclusion that it is manifest that during the period of woman's menstrual life her mental, physical, and social welfare depend greatly upon the continuance of the catamenial and reproductive functions. Therefore, the conservation of those organs which preside over these functions is of the utmost importance, and should be so regarded by the physician.

The fatality of chronic diseases of the ap-

pendages is greatly overrated, and that factor need not greatly disturb us or hurry us on to hasty operative interference by abdominal section. Polk's method of curetting the womb and packing its cavity is commended.

Many women with adherent tubes and ovaries, and pus in these organs, suffer either no inconvenience whatever or very little indeed from that condition *per se*. There are, again, others who have pains and aches only at their monthly periods. Let, however, their health break down from grippe, from influenza, from malaria, from overwork, or from nerve-strain, then symptoms may arise from their hitherto latent pelvic lesions. In most of these cases no surgical operation whatever is needed; for, if the woman can be restored to her former condition of health, she will lose her local symptoms and become symptomatically well. Goodell reports curing cases with all the objective and subjective symptoms of ovarian or of tubal abscess by the use of rest, massage, and electricity, by a general building up of the whole system, and by topical treatment. In some few of these cases this treatment was followed by conception, pregnancy, and parturition.

Supposing simple therapeutic measures fail, or that the use of the curette and of uterine drainage are not followed by relief and the surgeon is driven to surgical interference, after breaking up the adhesions, he should never remove the healthy appendage unless the menopause has been already established, or unless there exists a good reason for hastening it on, such as the presence of a uterine fibroid or of uterine disease or the insanity of the patient. On the other hand, should both ovaries be intrinsically diseased, and their tubes contain much pus, both uterine appendages should be totally removed no matter what the age of the patient. Generally the pus is limited to the tubes, and in that case one ovary, barring its adhesions,—which, of course, must be broken,—is healthy enough to be left behind. In such case the tube alone, if possible, should be removed, and not the healthy ovary, or the healthy ovaries, if both happen to be sound. Nor is it needful to remove the womb on account of disease of its adnexa. Some of the author's most notable cures have been in cases in which the tubes were so rotten that they were either pinched off close to the womb, or else were removed by a wedge-shaped incision in the womb itself, the uterine wound either being closed by suture or seared by the actual cautery.

In such cases, unless contraindicated, Goodell endeavors to leave behind at least a small fragment. In several cases in which a piece of

an ovary not larger than a bean was left behind, not any menstrual or sexual changes whatever took place in the women. Should the uterine appendages be merely adherent and not intrinsically diseased to any extent during active menstrual life, they should be released, and, perhaps, the worse of the two extirpated, but not both.

From his own large experience, Goodell states that in the majority of women who have been castrated the sexual impulse soon abates in intensity, much sooner than after the natural menopause; and that in many cases after the lapse of a few years it wholly disappears.

#### NEPHRITIS IN ITS SURGICAL ASPECTS.

KEYES (*American Journal of the Medical Sciences*, June, 1894) reaches the following conclusions after a thorough discussion of the above subject:

1. Healthy urine is sterile.
2. Purulent urine is always microbic.
3. Microbic infection takes place from within the body by a number of methods in the course of disease; it is often brought about by instrumental manoeuvres on the part of the surgeon.
4. A healthy organism and vigorous bladder may cope successfully with microbic invasion and rid itself spontaneously, or with a little aid, of all damage arising therefrom, showing little or even no inflammatory response.
5. A suitable condition of the patient's soil is essential to the propagation and perpetuation of inflammatory phenomena upon the urinary tract, after microbic invasion.
6. This condition, intensified by traumatism and physical weakness, notably of the degenerative variety, is most intense when there is vesical distention with atony, and when the ureters are dilated and the kidneys involved in the changes incident to tension below,—namely, atrophy and sclerosis above, with or without surface catarrh.
7. Under these circumstances surgical pyelonephritis is most likely to declare itself as a result of microbic infection from below (occasionally from above), in the course of suppurative disease or after operative interference.
8. Asepsis, antisepsis, and sterilization of urine are ends to be aimed at in genito-urinary surgery; but, like all other greatest goods, not yet attained in perfection. Much, however, can be done by local means in a prophylactic and curative way; little by internal medication, and possibly as much more than by any other means by flushing the urinary passages with natural mineral waters.

*TAPPING OF LATERAL VENTRICLES.*

FRANK (quoted by the *Universal Medical Journal*, June, 1894), after a study of the subject of tapping of the lateral ventricles, comes to the following conclusions: 1, For distention of the ventricles from acute, simple, or tubercular meningitis, is clearly indicated, and, other things being equal, promises recovery; 2, for effusion of blood into the ventricles from trauma or disease, makes recovery a possibility; 3, for abscess involving the ventricles, is immediately and imperatively demanded; 4, for effusion into the ventricles from brain tumors, may afford relief to symptoms; 5, for chronic hydrocephalus, moderate distention of the ventricles, without enlargement of head, may afford relief; 6, for chronic hydrocephalus, great distention of ventricles, enlargement of head will lead to a fatal result.

*HOT BICHLORIDE POULTICE.*

ROGERS (*Northwestern Lancet*, June 15, 1894) warmly commends, in the treatment of variously assorted septic conditions, bichloride poultice after incision and for drainage. Where this is necessary, the affected part is splinted and is completely enveloped in hot bichloride gauze, or cloths wrung in a hot 1 to 3000 bichloride solution. Over this is placed a thick layer of absorbent cotton wrung out in the same solution. The whole is entirely covered by a pad of oiled silk, retained in position by a roller bandage. He holds that wherever the ancient flaxseed poultice is indicated, the bichloride can be substituted with eminently more satisfactory results.

*THE VALUE OF CAUSTICS IN THE TREATMENT OF MALIGNANT DISEASE.*

In the discussion of the above subject at the meeting of the American Medical Association, in the Section on Surgery, held in San Francisco, June 5, 1894, which was opened by Dr. H. O. Marcy, he stated his belief that malignant disease is, 1, local; 2, constitutional. Also, he receives far better results from local operations by the use of the knife, carefully eliminating the tissue wide of the area of disease, so far as we can ascertain its position. He believes caustics simply make an open wound subject to further infection.

DR. SHIELDS called attention to the fact that when we apply a caustic, no matter how slight or how strong it may be, with the hope of curing a malignant disease, we are applying it to a tissue which is undergoing rapid cellular

change, and are liable to make a non-malignant growth a very malignant one. He also points out that there is a condition in post-syphilitic gummatous growths which does not allow of immediate cure by the use of iodide of potassium, and that one should give a very careful consideration, especially to tumor of the tongue of syphilitic history before he proceeds to remove the tongue.

DR. GRISWOLD agreed with the foregoing conclusions and reported the case of a woman coming to him for operation five years ago. Her system was involved, but through the operation she has lived much longer than she possibly could have done without operation or recourse to milder measures. This reporter describes his method of applying caustics in epithelioma on the face, hand, or lip, where the patients refuse to submit to the knife. The caustic is made of sulphate of zinc, dried so that the water of crystallization is all driven off by heat, till it bubbles up after the water of crystallization is driven off, and then powdered in a mortar promptly and quickly, so that it shall not absorb water from the air; put it in a bottle and pour in enough chemically pure sulphuric acid, so that when it stirs up it will make a paste so thick that when you put a little stick or little glass rod in it, a good-sized drop will adhere to that stick or glass rod and not drop off. Have plenty of absorbent cotton or plaster, and apply that all over the surface. It is a little painful, but in about ten minutes it destroys the tissue to the depth of about one-eighth of an inch. Then take the point of your pen-knife and scrape it off until it begins to bleed, to the quick; then apply it again, and after four or five applications the physician must use his judgment as to whether he has got the cells out or not. Dr. Griswold has met with but one failure in twenty operations. It may take an hour and a half or two hours, according to the size of the epithelioma. Any simple ointment is afterwards applied.

ILLUSTRATED DICTIONARY OF MEDICINE, BIOLOGY, AND ALLIED SCIENCES. By George M. Gould, A.M., M.D. Philadelphia: P. Blakiston, Son & Co., 1894.

We are told in the title-page of this magnificent work of reference that it includes the pronunciation, accentuation, derivation, and definition of the terms used in medicine and the various sciences closely related to that art, and

on looking through the sixteen-hundred-odd pages of which the work is composed, we cannot help being impressed with the fact that the author has carried out to the letter the statements as to the scope of the work contained on his title-page and in his preface. The author very distinctly prefers the newer methods of spelling which he has introduced into the columns of the *Medical News*, of which he is editor, but has been sufficiently broad in his ideas to give the spelling of many words in both the new and old form, although throwing his influence in favor of the former. He advises the dropping of the diphthong, and distinctly favors phonetic spelling. So far as we can judge, the dictionary deserves to at once take a high rank among the medical lexicons of the world. It cannot, of necessity, be as full as is that of Foster, with its four enormous volumes, nor as ready for reference as the smaller dictionary which Dr. Gould has already prepared. As it stands, it is a work showing not only a wide knowledge of all those branches of learning required of the lexicographer, but as a marvellous piece of work to have been done by practically one individual. In such a book mistakes must necessarily occur. Thus we notice that the old-fashioned and practically useless antidotes for phosphorus are given under phosphorus, on page 1072,—namely, sulphate of copper and French oil of turpentine. The first of these has been proved to produce death more rapidly than the phosphorus, and the second to be absolutely unobtainable under ordinary circumstances, and useless when employed. Again, in the table on poisons, on page 1136, we notice that acetanilid and antipyrin are characterized as corrosive poisons, which they certainly are not under any circumstances. Much less can they be considered such if Dr. Gould's own definition is to be relied upon,—namely, "a substance that destroys organic tissue either by direct chemic means or by inflammation and suppuration." These drugs may destroy the blood and other tissues by direct chemic means, but certainly not by what we ordinarily mean by a corrosive action. We also notice that under the remedial measures to be employed in poisoning by chloroform, strychnine is not mentioned, and in poisoning by the various poisonous fungi nothing is said of the value of atropine, which is practically a specific in many such cases. Under snake-bite no mention is made of the value of permanganate of potassium and strychnine, which are certainly the two most powerful antidotes that we have to-day, as proved in the case of the first drug by the experiments of Weir Mitchell and

Reichert, and its practical application by many clinicians, while the employment of strychnine has been heralded the world over with an enormous number of successful cases by its originator, Dr. Müller, of Australia, and many of his followers.

### NOTE ON STRYCHNINE NITRATE IN DIPSOMANIA.

To the Editors of the THERAPEUTIC GAZETTE.

DEAR SIR:—It seems to me time that some one should file a demurrer to the emphasis which is given the acidulous radical in the literature upon the use of strychnine nitrate in dipsomania and allied states. Strychnine and nux vomica were used for the alcohol habit half a century ago, and its therapy in these cases is exactly based upon its physiological action. This dynamic action resides in the alkaloid and not in the acidulous radical of any of its salts. Any salt in appropriate dose will produce that therapeutic effect which is considered very valuable by all clinical observers with experience in treating drunkards and tobacco users.

In modern times a royal road to notoriety has been discovered, the toll on which is simply to present some rare base combined with an old and valuable acid, as a new bromide, and then publishing a paper on the "new" drug in the old diseases in which the old salts have been long used, or else some old base is combined with an acid which forms a salt not much used, and the "new" salt is highly lauded as a discovery in therapeutics. In the present case the profession seems to have even followed the lead of the leading charlatan of the century, and to consider nitrate of strychnine a new remedy without a substitute.

A somewhat large clinical experience carefully digested, has enabled me to say to those who learn only at the bedside, that sulphate of strychnine is equally as valuable as is the nitrate in the treatment of all habits. The proper and scientific method of expression is to use the term strychnine in discussions of this subject. As regards the facts, I regard strychnine as simply invaluable in all cases of alcohol, tobacco, or morphine habit, especially after the cure is nearly completed.

### THE PHARMACOLOGY OF FOURTEEN MEXICAN PLANTS.

A PAPER PRESENTED TO THE SECTION ON THERAPEUTICS OF  
THE PAN-AMERICAN MEDICAL CONGRESS.

BY FERNANDO ALTAMIRANO, M.D., CITY OF  
MEXICO.

I WISH to present to the Pan-American Medical Congress the results obtained by several Mexican physicians in the study of some indigenous plants. I have compiled whatever work has been accomplished by the Instituto

Médico Nacional (National Medical Institute) regarding the botanical classification, chemical composition, and physiological action of said plants, and in many cases I will refer to their most common therapeutic applications. May this study prove of some interest to the distinguished members of the Congress.

*BOCONIA ARBOREA (Watson—Papaveraceæ).*

*Habitat.*—This plant is known in Michoacan under the common name of inguande, in Morelos under that of llora-sangre (weeping-blood), and in Córdoba it is called gordolobo. It grows abundantly in Michoacan, near Uruapan and

Tengambato. The part of the plant most generally used is the bark. This yields a yellowish juice which contains the active principles. According to M. Lozano (1893), the bark has the following

**Chemical Composition.**—Water, 10,000; salts, 9500; fats, 1320; acid resin, 9364; boconine (alkaloid), 5116; gum, 1875; dextrin, 5775; oxalic and tartaric acids, 2430; coloring matters, cellulose, etc., 44,990; losses, 9620. The alkaloid was termed *boconine* by Lazo de la Vega, who also made an analysis of the bark. The substance known as boconine is really a mixture of several alkaloids. Lozano has determined four of these, which he has named as follows: *Boconirubine*, *boconixanthine*, *boconichlorine*, and *boconiiodine*, names given on account of the coloration they produce with concentrated sulphuric acid (in the order in which the alkaloids are mentioned),—that is, red, yellow, green, and violet. Again, the salts of the first body are red, those of the second body yellow, and those of the third and fourth alkaloids white. All these salts are crystallizable.

**Physiological Action.**—Boconine, a mixture of three alkaloids, produces anæsthesia of the peripheral nerves at the point of injection. This is followed by an action on the nerve-centres, causing vascular dilatation and hemorrhages. While the drug exercises cerebral disturbances, it does not produce loss of consciousness. The powder of the drug, administered by the stomach, causes emetic effects, due, probably, to the presence of resinous principles.

**Therapeutic Uses.**—The powder has been applied, with good effect, to produce local anæsthesia in surgical operations.

*CACALIA CERVARIFOLIA (D. C.—Compositæ).*

**Habitat.**—State of Chihuahua. The plant is commonly called *matarique*, the word signifying "pain-killer." The root, the part of the plant in common use, has an aromatic odor and a bitter taste, and is covered with yellow resinous points.

**Chemical Composition.**—Cacalia contains the following: Resin, essence, glycogen, tannin, glucose, and an alkaloid.

**Physiological Action.**—In doses of .10 gramme, the alcoholic extract of the plant causes in frogs paralysis of the voluntary muscles, diminished sensibility, and cardiac arrest. On dogs, an intravenous injection of the same extract, of .50 gramme, produces general analgesia, depression of cardiac energy, and respiratory disturbances, all these phenomena disappearing in the

course of two hours. In man, 30 grammes of the tincture have caused vomiting, intestinal pain, diarrhoea, cramps, and lypothymic symptoms.

**Therapeutic Uses.**—Externally, the drug, in the form of frictions, is serviceable in the pains of neuralgia, excoriations, and burns; its antiseptic properties enhance the cicatrization of wounds. It has been employed against putrid dyspepsias, constipation, and meteorism. Its principal use, according to Dr. Ceballos, is as an analgesic to combat muscular, rheumatic, and articular pains.

**Administration.**—The tincture is given in doses of from 15 to 30 grammes, but its effects on the heart should be carefully watched. Externally, it is applied to wounds in the form of a watery solution of the strength of twenty per cent.

*CALEA ZACATECHICHI (Schl.—Compositæ).*

**Habitat.**—Córdoba and Orizaba, of the State of Vera Cruz. Its common name—*zacatechichi*—signifies "bitter herb." It is certainly very bitter, and is used by the laity in certain diseases of the stomach.

**Chemical Composition.**—According to Armendáriz, *calea* contains chlorophyll, coloring matter, essential oil, acid resin, a volatile acid, a bitter principle, tannin, and salts.

**Therapeutic Uses.**—In the hospitals the plant has been employed, with good results, in the treatment of dyspepsias, gastric catarrh, anorexia, atonic diarrhoea, etc. The remedy increases the appetite, facilitates digestion, and combats constipation.

**Administration.**—A decoction in the proportion of five per cent., the extract in 1-gramme doses every twenty-four hours, and the tincture in quantities of 4 grammes in the same time, are employed.

*CALLIANDRA GRANDIFLORA (Benth.—Leguminosæ).*

**Habitat.**—This plant, commonly known under the names of *pambotano*, *xoloxochitl*, and *cabellitos*, vegetates in the States of Vera Cruz, Morelos, and Michoacan, and in the Valley of Mexico. The parts of the plant used are the rootlets, which are rhizomes, of a fasciculated, tortuous, fibrous, and woody character, having a peculiar persistent acrid taste.

**Chemical Composition.**—*Pambotano* is made up of fatty matters, wax, essence, tannin, resin, red coloring matter, and a glucoside.

**Action and Uses.**—A decoction or the extract of the plant produces no marked effect on frogs or dogs, whether the substance is administered

by the stomach or subcutaneously, once or for several consecutive days. In man, it has been tried in numerous cases of malarial disease, but so far it has proved of no avail. The remedy has never caused the disappearance of the hæmatozoa of Laveran. The plant cannot, therefore, be considered as a reliable drug to use in the treatment of intermittent fevers, notwithstanding its great reputation as an antiperiodic among the laity. It might be of service in chronic paludal intoxication, to combat the diarrhoea and gastric disturbances, owing to its antiseptic properties. A decoction is the preparation most commonly employed. Sixty grammes of the plant are placed in five hundred grammes of water. This is boiled until it is reduced to two-thirds of the original amount. Long boiling is necessary to dissolve the extractive principles.

*CORIARIA ATROPURPUREA (D. C.—Coriaria).*

*Habitat.*—*Coriaria* is also known as tlalocopetate, and is abundantly found in Ameca-Ameca, of the State of Mexico. It is highly poisonous, and cases of poisoning occur every year among country children who eat the fruit.

*Chemical Composition.*—According to Francisco Rio de la Loza, *coriaria* is composed chiefly of water, fats, resin, tannin, gallic acid, yellow coloring matter, coriamartine (active principle), and salts. Coriamartine is a solid white substance, made up of hexagonal crystals. It is but little soluble in cold water; it is readily so in alcohol, ether, and chloroform. Sulphuric acid gives to it at first a yellow color, decomposing afterwards with the production of a white powder-like substance. Hydriodic acid gives with the drug a clear yellow hue. The volatile and fixed alkalies give to solutions of coriamartine a rose coloration, which soon turns yellow.

*HECTIA GLOMERATA (Zucc) AND H. HARGENTEA (Baker—Bromeliaceæ).*

*Habitat.*—The common name of this plant is guapilla. It is abundantly met with in the States of San Luis de Potosi, Querétaro, in Mixtecapan, and other points. It is especially found in rocky soils. The laity use the plant as food, for emollient applications, and as a remedy for pneumonia. At the base of the leaves, on both sides, is found a yellow substance, giving the appearance of a coat of varnish. By rubbing the leaves together this coat is loosened in adhesive, thin plates, consisting of a balsam or vegetable wax, having, according to Armendáriz, the following

*Chemical Composition.*—Essential oil, 2600;

benzoic acid, 5733; acid resin, 79,267; neutral resin, 2100; gum, 40; mineral salts soluble in water, 1360; mineral salts insoluble in water, and losses, 8800. This natural product, owing to its chemical composition, has been classified as a body analogous to benzoin, but presents different peculiarities. It may be known under the name of *bromelian benzoin*. Its properties are these: It has a greenish-yellow color, an aromatic odor, and somewhat sweetish taste; it is soft, and can easily be compressed between the fingers. It melts at 72° C., and has a specific gravity of 1.183 at 18° C. The substance is inflammable, and burns with a smoky reddish flame, producing an odor of benzoin. It is soluble in sulphuric ether, absolute alcohol, and in a mixture of alcohol and chloroform; it is almost insoluble in water, in petroleum ether, in benzine, sulphide of carbon, and alcohol at 50° C. The product exhibits a dark-green color with nitric acid; a green, turning into a violet-blue, with sulphuric acid. The alkalies dissolve it, producing a reddish liquid. By a process of sublimation, in the presence of alkalies and water, benzoic acid has been obtained, but this acid was not obtained by the dry method. The applications of bromelian benzoin depend upon the composition of the drug. It may be used as a substitute for the benzoin balsams, etc. The remedy under consideration may be obtained at a low cost, owing to the abundance of the plant from which it is extracted.

*ERYTHRINA CORALLOIDES (D. C.—Leguminosæ).*

*Habitat.*—This tree is vulgarly called tzompantle; the seeds are known under the name of "colorines" or "patoles." The plant grows in the Valley of Mexico and other places. It is cultivated in the gardens. The wood is used for the manufacture of corks; the flowers are employed as an article of food; the seeds are poisonous. According to the studies of Francisco Rio de la Loza, *erythrina* has the following

*Chemical Composition.*—Water, 7.15; fats, 13.35; resin soluble in ether, .32; resin soluble in alcohol, 18.47; alkaline substances, 1.61; albuminous matter, 15.87; mineral salts, 89.15; losses, .68. According to the investigations of the writer, presented to the Mexican National Academy of Medicine on July 27, 1887, the extract of *erythrina* has the following substances: Coralloidine (convulsant), coralline (inert or little active), erythroidine (powerful motor paralyzant), erythric acid (inactive), erythro-resin (emetic), an inert principle, fats,

glycogen, coloring matter, mineral salts, resin. Summarizing the physiological action of this extract, it may be said that it paralyzes the terminal plates of the motor nerves, produces convulsions, and acts as an emetic.

*Therapeutic Uses.*—The extract of erythrina has been recommended in the treatment of tetanus and epilepsy, in chorea and similar disorders. There appears to be no indication for its use as an excitant. The drug is a sure emetic for the lower animals, especially in the case of birds.

#### GAULTHERIA OVATA (*D. C.*—*Ericaceæ*).

*Habitat.*—This plant is popularly known under the name of axocopaque. It grows abundantly near Huauchinango, in Orizaba, and Jalapa. The whole plant is aromatic, and is quite frequently used as a perfume in churches and in private houses. The ancient Mexicans employed it to perfume their clothing and to preserve this from the action of moths. It was also used internally in the treatment of various diseases.

*Composition and Uses.*—The plant contains twenty per cent. of essential oil, which may be considered as the active principle, and is analogous to the essence of winter-green or *Gaultheria procumbens* of the United States of North America. Its antiseptic, diuretic, and antirheumatic properties have been made use of in practical medicine. It is especially employed in the treatment of rheumatic affections of children, as possessing advantages over the salicylate of sodium. As an antiseptic, the active principle of *Gaultheria ovata* is as efficacious as either salicylic or phenic acid, without being so toxic. It is to be preferred in the antiseptics of mucous membranes and external wounds. An infusion of the drug is the form of preparation most commonly used. This is prepared in the strength of ten per cent. It is easy to take in this manner, and is for a long time well borne by the stomach.

#### MONTANOA TOMENTOSA (*Llav. and Lex*—*Compositæ*).

*Habitat.*—Zihuatli, the Aztec name of this plant, signifies woman's medicine. It is quite common all over the republic, especially in the Valley of Mexico.

*Chemical Composition.*—Dr. Armendáriz has recently pointed out the following ingredients: Acid resin, 2140; neutral resin, 3026; chlorophyll, 27,500; organic acid (montanoic), 1560; vegetable wax, traces; gum and other principles, 2015; tannin, which colors green the salts of iron; mineral salts, 12,560; cellulose,

22,824; extractive matter, 10,110; essential oil and losses, 4705. Montanoic acid, first described by Professor Federico Altamirano, is considered the active principle of the plant, and to which its influence on the uterus is due.

*Physiological Action.*—A decoction of the leaves, given by the stomach, causes powerful uterine contractions. Montanoic acid, subcutaneously administered, produces intense pain at the point of injection, and contractions of the arterioles. For the latter effect the dose is .10 gramme, which does not cause toxic phenomena. The vaso-constrictor action of the acid is analogous to that caused by ergot. The difference lies in that zihuatli acts on the uterus, rather than on the arterioles, to produce a hæmostatic effect. Montanoa, it may be said, causes uterine contractions especially; ergot, contractions of the uterus and of the arterioles; while hydrastis affects the arterioles particularly.

*Uses.*—Zihuatli is used to increase the contractions of the gravid uterus and to enhance uterine subinvolution.

#### PSORALEA PENTAPHILLA (*Linn.*—*Leguminosæ*).

*Habitat.*—This plant grows in Querétaro, Guadalajara, Guanajuato, and other places. It is commonly called "contrayerba de Querétaro," or "whitw," or "aromatic contrayerba." The part of the plant used is the root. This appears in the form of a tuberous rhizome, four to eight centimetres long, of a brown color externally and white internally, very feculent, and having a peculiar odor. It is used by the laity as an antiperiodic and for toothache.

*Chemical Composition.*—According to M. Lozano, psoralea has the following composition: Water, 10,000; salts, 3750; fatty matter, melting at 60° C., 1880; gum, 6806; glucose, 1440; starch, 26,500; albumin, .100; cellulose, 28,750; a crystallizable acid, .400; psoraline (alkaloid), 9250; losses, 6154. Psoraline is a crystalline body of a white color, soluble in water and in alcohol, but insoluble in sulphuric ether, chloroform, and benzene. It has an aromatic odor similar to that of the root, and a bitter taste. It is precipitated by the alkaloidal reagents. With sulphuric acid, psoraline gives a violet color, which passes into green and afterwards into Prussian blue; with nitric acid it produces a light-greenish hue, which is changed to red by the action of chlorine and ammonia.

*Physiological Action.*—In doves, psoraline, in doses of from .25 to .50 gramme, subcutaneously injected, produces vomiting, muscu-

lar relaxation, and lowering of the temperature, and it may, therefore, be considered as an emetic and antithermic drug (Altamirano). According to the experiments of Dr. Tous-saint, made in the Instituto Médico Nacional, psoraline acts as an antithermic by influencing the nervous mechanism centrally.

*Therapeutic Uses.*—Although strongly recommended by the laity as an excellent antiperiodic remedy, Dr. Torres, who has tried it in the Hospital of San Andrés, found the drug of no value as such. The medicament reduced febrile temperature from  $1^{\circ}$  to  $2^{\circ}$  C. in the course of an hour, this depression lasting for about two hours. It has been employed in doses of .016 gramme. Psoraline may be considered as a good antipyretic, since it does not cause untoward effects.

ROUREA OBLONGIFOLIA (*Hook and Arn.—Conaraceæ*).

*Habitat.*—The common name of this plant is "chilillo de la Huasteca." It grows in the States of San Luis de Potosi and Vera Cruz especially, and also in other places. It is a creeper. Its fruits are eaten by certain birds (the species *Penelope purpurascens*), and the bones of these are said to be poisonous to dogs. I have made no observations in this respect. The root of the plant, however, is used to poison dogs, and also for tanning purposes, owing to the large quantities of tannic acid which it contains.

*Chemical Composition.*—According to Dr. Godoy, who has made a preliminary examination, rourea contains the following substances: Fatty matters, coloring matter, resin soluble in alcohol, resin insoluble in alcohol, tannin in abundance, a bitter principle, glucose, gum, and several other principles.

*Physiological Action.*—Four grammes of the powder administered to a dog by the stomach have produced tremors, general clonic convulsions, difficult respiration, paralysis, and dilatation of the pupil. These symptoms are slowly developed, appearing in the course of three or four days and lasting for a long time, this being especially the case in regard to the motor paralysis. In the frog, motor paralysis and cardiac disturbances are also observed (Altamirano). The plant has no use in practical medicine at present. It is employed for the purposes already mentioned.

SENECIO EHREMBERGIANUS (*T. W. Klatt—Compositæ*).

*Habitat.*—This plant grows in the States of Puebla, Zacatecas, Guanajuato, and others. It

is commonly called "yerba de la Puebla" and "izcuimpatli." Rio de la Loza gives the following

*Chemical Composition.*—Water; fatty matters; resin, gum, senecic acid (active principle); salts. Senecic acid occurs as a colorless, odorless, insipid liquid, very soluble in water, alcohol, and sulphuric acid. It reduces by heat the salts of silver, gold, Fehling's solution, etc. It is not precipitated by chloride of iron, chloride of barium, chloride of calcium, lime-water, sulphate of magnesium, etc. It reduces the bichloride of mercury to calomel. It gives no color with the concentrated acids. It easily forms senecates by saturation or by decomposing the carbonates. The alkaline senecates are deliquescent. With acetic acid and a base acetoseneccates are easily formed, these appearing in a crystalline form. This would prove to be the most useful form for pharmaceutical preparations.

*Physiological Action.*—The aceto-senecate of baryta, after a dose of .40 gramme, subcutaneously administered, produced death in a dog in the course of three hours.

THALAUMA MACROCARPA (*Zuc—Magnoliaceæ*).

*Habitat.*—Thalauma is popularly known as "yoloxochitl," or "flower of the heart." It grows in the State of Morelos, but particularly near Motzorongo, in the State of Vera Cruz.

*Chemical Composition.*—According to Dr. Armendariz, yoloxochitl contains: Fatty matters, acid resin, indifferent resin, essential oil, coloring matter, a bitter extractive, thalaumine, a resinous glucoside, and salts.

*Physiological Action.*—Experiments made with the extract of the seeds have shown that thalauma alters the red blood-corpuscles, coloring them black, produces phenomena of asphyxia, modifies the pulse-rate and the arterial pressure, and causes also decided nervous disturbances. Death is caused by cardiac paralysis (Altamirano).

*Therapeutic Uses.*—The tincture of thalauma, prepared from the flowers, is commonly used for palpitation of the heart. At present it is being tried in the hospitals.

THEVETIA ICCOTLI (*D. C.—Apocinaceæ*).

*Habitat.*—This plant, commonly known under the name of "codo de fraile," or "yoyote," grows in the States of Morelos, Michoacan, and other places.

*Chemical Composition.*—The seeds—the part of the plant in common use—contain chiefly fatty matters and thevetin, a glucoside, the active principle. Thevetin is highly poisonous,

crystallizing in colorless, brilliant plates, having a bitter taste. It destroys sensibility when placed upon the tongue, and it also acts as a powerful irritant to the nasal mucous membrane. Thevetin is little soluble in water, readily so in alcohol, and less so in sulphuric ether. Thevetin is changed into *thevetinine* (?) by acids. This last body reduces Fehling's solution.

**Physiological Action.**—Thevetin is easily absorbed by the stomach and from under the skin. It acts especially upon the heart. In the dog, in doses of 3 milligrammes, it produces, in the course of fifteen minutes, an irregular pulse, a rise of the arterial pressure, vomiting, insalivation, contraction of the trachea and probably also of the bronchial tubes, a frequent respiration, and phenomena of asphyxia. In about forty minutes there occur a depression of the arterial pressure and paralysis of the heart. It does not cause diuresis. The heart is arrested in systole. In the frog, the heart, before it is finally arrested, undergoes a period of paralysis or partial relaxation of its ventricular walls.\*

**Therapeutic Uses.**—The medical uses of the plant have not been studied as yet. The drug may be classified as an emeto-cathartic and cardiac paralyzant. It appears to be contraindicated particularly in mitral affections of the heart.

CITY OF MEXICO, August 28, 1893.

#### DIPHTHERIA, THEORETICALLY AND PRACTICALLY CONSIDERED.

A PAPER READ BEFORE THE SCHUYLKILL COUNTY MEDICAL SOCIETY.

BY JAMES STRATTON CARPENTER, M.A., M.D.,  
POTTSVILLE, PA.

THE present trend of scientific investigation in the realm of medicine is towards the discovery of a local cause for disease. It is the supreme effort on the part of investigators to isolate the disease-bearing germ and to learn its natural history,—its *habitat*, its *modus vi-*

*vendi*,—and in so doing to arrive at the starting-point of the diseased process before it shall have become a systemic affection. *A priori*, if such results were obtainable, it would very naturally simplify our methods of treatment; but practically, as we consider the various results thus far reached by scientific men, can it be asserted that in each instance where a local origin has been satisfactorily determined upon as the source of constitutional infection we have arrived at any surer methods of treatment in that disease, or have observed any lessened mortality as the result of that treatment? Does the discovery of the typhoid germ deserve the credit of the cold-bath treatment instituted by Brandt for enteric fever, a treatment which has certainly robbed that dread disease of its terrors and reduced its mortality to *nil*? Has the knowledge of a pneumococcus in any degree lessened the number of deaths which annually occur from pneumonitis, and is it not a fact that statistics show, if anything, an increased mortality from that disease in these days over what obtained from older methods of treatment, when bloodletting had not yet fallen under the ban of "higher medical criticism"? Given a case of cholera, or of tuberculosis, or of enteric fever, in each of which diseases the specific germ has been determined, and have we in any respect benefited our patient through the knowledge, experimentally determined, that their respective bacilli stand in a causal relation to each of these diseases? Have we ascertained that the "tuberculin" possesses any power over the tubercular process, and have we thereby acquired any greater control over cholera or enteric fever than might be due to the teachings of a rational therapeutics entirely uninfluenced by any germ theory of disease? Let them isolate the *materies morbi*,—the germ,—make cultures thereof, and inoculate the guinea-pig therewith, producing the same disease from which these cultures were originally obtained, and while an interesting study has been satisfactorily rounded out to its legitimate conclusion, in what respect is suffering humanity aided thereby? The utility of such investigations, it seems to me, must be limited to their bearing upon pathological processes in the light which they throw upon the natural history of disease, as well as the lessons they teach in regard to preventive medicine, but nothing more. As an example, take diphtheria. If there be a disease well calculated to try the resources of the physician to the utmost, and to test his faith in the saving power of medicines, it is to be found here. Attacking its victims often insidiously, it lies in ambush, as

\* We may say in this connection that as far back as 1879 an elaborate research of the physiological actions of *Thevetia iccotti* was made by Dr. David Cerna, constituting one of the inaugural dissertations to which a prize was awarded by the University of Pennsylvania. The paper was published in the *Philadelphia Medical Times* of May 24 and June 7, 1879. The chief conclusions arrived at by Dr. Cerna concerning the actions of thevetin appear to be confirmed by Dr. Altamirano. We are also acquainted with the fact that among the laity in Mexico an ointment made with the powdered seeds of thevetia is used in the local treatment of hemorrhoids.—ED.

it were, until with irresistible onset it invades all the air-passages, and, despite every effort made to combat it, proves fatal in an incredibly short space of time; or, with more gradual onset, it makes itself known by the usual symptoms of malaise and fever, and, running a more protracted course, takes possession of all the outposts of the respiratory tract with a tenacity that knows no yielding, until the life-centres, poisoned by the very fluid that should bring renewed vigor, fail to exercise their functions, or the heart-muscle, paralyzed by the baleful effects of the diphtheritic poison, gives up the struggle, perhaps at the very moment when we had esteemed the battle won in the eradication of all the local evidences of the disease. And why should statistics show such terribly fatal ravages of diphtheria in these enlightened days of scientific investigation, when the nature of the disease has been so thoroughly worked out that the Klebs-Loeffler bacillus is regarded by the medical world at large as the causative factor in the disease, and the theory of its local origin is practically unquestioned? Can we regard these investigations of any *real* import to disease-stricken humanity, if, while experimentally determining a specific germ to be the causal agent of diphtheria, the remedy is lacking whereby the system may be freed from that germ before its multiplication within the tissues shall have made cure an impossibility? "The cry of Rachel weeping for her children," and who is not to be comforted by promises of still more extended laboratory research, must be met with something that will insure a lessened rate of mortality in this dread disease of childhood, that destroys far too many victims, if the boasted advances in medical science of to-day are to win the confidence of those for whose benefit they were undertaken.

Does not, on the other hand, a close study of disease itself, and especially of those cases which have proved fatal in spite of the best-directed efforts, yield more substantial fruits than unlimited investigations as to the nature of certain bacilli, and result in more positive knowledge, which means improved methods of treatment, of the diseases in question? We cannot be blind to the good results thus far obtained by bacteriologists, and the world at large must ever remain debtor to such master minds as Koch, Pasteur, and others of that ilk. But we should not, on that account, abandon the direct teaching of clinical investigation, because, forsooth, the latest dogma propagated from the laboratory of even such a man as Robert Koch tends to overthrow that faith which the humblest practitioner should never

surrender unless forced thereto by every proof which clinical study alone affords. We must, then, while learning the lessons which bacteriology teaches, not be led astray by that ill-timed enthusiasm which would make of this mortal clay something which even its Creator never purposed it to become,—invulnerable to disease,—but apply those teachings to the best defence of that system which at every avenue we know to be so liable to attack. In other words, the same truism is to be stated here which may be declared of not a few diseases to which mankind is heir: there is no specific remedy for diphtheria. In spite of all the investigations made into the nature of the bacillus of diphtheria, or of the disease itself, no one has yet discovered a single remedy which, *facile princeps*, can in every case successfully cope with that arch-enemy of childhood and cause it to be proclaimed to the medical world as an infallible antidote to the diphtheritic poison. In spite of a general acceptance of the theory of the local origin of diphtheria,—a thesis first defended in a paper read before the American Medical Association at its meeting in Buffalo, N. Y., in 1878, by the writer's father, Dr. John T. Carpenter,—we must yet explain those cases of the disease which arise without any apparent local infection, and thus oppose themselves to that theory, presenting at the onset all the symptoms of a general disease with secondary manifestations in the tonsillar region. Clinical studies, however, including cases of each variety, must, when faithfully carried out, prepare the physician for meeting whatever complications may arise with the best possible measures for the relief of his patient, and, while reposing confidence in no special remedy, lend him such resources as will not fail him when the hour of need is sorest. He will not be biassed, either, towards the local view so strongly as to withhold the much-needed general remedies from his little patient, nor will he neglect the use of those topical remedies which are most certainly demanded in the careful management of every case of diphtheria, even though his prejudices should largely incline him to the belief in the general character of the disease.

These reflections are the expression of the writer's convictions based upon the results of a general practice of the past ten years, covering repeated outbreaks of the diphtheritic disease in which most malignant types of cases have been successfully treated, while others equally malignant have failed to yield to the measures employed for their relief. The treatment of diphtheria pursued by him in the case which must be his apology for this paper will best be

described in connection therewith, and while presenting nothing startling in its novelty, will, he thinks, prove of interest in demonstrating what he believes to be the cardinal principle in the successful management of the gravest of diphtheritic complications,—heart-failure,—viz., the employment of “the ounce of prevention,” which, in these cases, is doubly worth “the pound of cure.”

CASE.—Edna B., a child of eleven years, was seized with scarlatina in the first week of April, which ran its course without any serious features. In two weeks from the onset of the attack she was convalescent, and in leaving her to maternal care strict injunctions were given that the child should not leave the room until desquamation was entirely completed, as the weather was very raw, and the lower parts of the house so damp that nephritis would certainly follow any such imprudence. Ten days later I was recalled to my patient, and found her again in bed, complaining of pains in her limbs and exhibiting an œdematous condition of the lower extremities. On examining the fauces, both tonsils and the naso-pharynx were found to be covered with a dirty grayish membrane which concealed the healthy mucous surface from view. Urinary examination revealed fifty per cent. albumin and some traces of sugar. A gargle was prescribed containing carbolic acid and Monsel's solution, and, internally, corrosive sublimate,  $\frac{1}{4}$  grain every two hours, with a highly nourishing diet, and whiskey as a needed stimulant. For three days this treatment was continued, but was then abandoned, as the ptyalism occasioned by it was so distressing that it was impossible to continue it longer.

In spite of the above measures the disease had steadily progressed, and now the isthmus faucium was completely blocked with what may only be characterized as a hideous mass of gangrenous tissue, which produced a terrible fetor, permeating the atmosphere of the entire dwelling with a sickening odor readily perceptible to one entering the house two stories below that on which the sick-room was situate. The surroundings of the patient could hardly have been worse for such a case. The sick-room was a small partition under the eaves, eight by ten feet, and the ceiling so low that one could stand upright in about half that space. There was but one window for ventilation, but the determined efforts of the child to get well negated these disadvantages and made up for all the deficiencies of her nursing, as she partook willingly of large quantities of nourishment all through the attack, and submitted to

all the measures necessary for her relief, however trying.

When compelled to abandon the use of corrosive sublimate, I felt as though the nearest approach to an antidote to the diphtherial poison that I knew of had been discarded, as I have employed it the past year or two in some very malignant cases and with marked success. Here was as formidable a case, however, as I had yet faced, and the chances of successfully opposing it were, in my opinion, reduced to a minimum when compelled to abandon the mercurial treatment. The diphtheritic deposit extended over the naso-pharynx, and the tonsils and soft palate were completely covered by it, the uvula being enveloped in a gangrenous mass that, with the hypertrophied tonsils, seemed to fill up the entire lumen of the pharynx. The pulse was feeble and very rapid (140 per minute), and the added difficulties of an acute parenchymatous nephritis seemed to render hopeless the indulgence in medication of any sort whatever. The indications to be met presented themselves to me as follows: the direct effect of the unavoidable absorption of so much septic material upon the red blood-corpuscles could only be met with iron, and iron in large doses, frequently repeated, if the desired effect was to be obtained.

Before such a large absorbing surface as that already involved could be freed from the putrid material implanted upon it, the added danger of the probable paralyzant effect of the diphtheritic poison on the heart-muscle must needs be guarded against, a complication that is most fatal in this disease, diphtheritic laryngitis not excepted. I accordingly prescribed the muriated tincture of iron in the dose of 15 drops every two hours and  $\frac{1}{8}$  grain of strychnine every six hours, as a commencing dose, and a teaspoonful of brandy every two hours; for topical use, a fifty-per-cent. solution of liquor sodæ chlorinat. was ordered for spraying the throat as frequently as every half-hour, and each morning and evening I made a thorough “swabbing out” of the throat, using the same solution. After the institution of this treatment, as there was no perceptible improvement in the child's condition from day to day, I rapidly increased the dose of the iron to 35 drops every two hours, and the strychnine granules were given every four hours; the brandy was administered each hour, and large quantities of milk and broths were taken each twenty-four hours. Under this increased dosage, continued for four days successively, I at last was able to observe the loosening edges of the gangrenous mass revealing the healthy mucous membrane

beneath, and in two weeks after the relapse noted she coughed up the entire cast of the naso-pharynx, which, unfortunately, I did not see, as the mother, unable to bear the stench, had burned it along with some infected cloths. Inspection showed the throat free from all membranes and *the uvula missing*, dissected out far more neatly than the surgeon's knife could have accomplished it. It is hardly necessary to particularize longer on the progress of this case, except to state that to-day—six months from my last visit—you have seen her perfectly well and entirely free from all traces of her recent illness, save in the absence of her uvula. In spite of the severity of the conditions met with, it is satisfactory to note that there was an entire absence of all paralytic conditions, even the paralysis of deglutition, often observed after mild cases of the disease, having been avoided. The function of the uvula, about which there is as much uncertainty as attends that of the appendix vermiformis, receives no enlightenment from the history of this case, except in a negative way. If, as some writers maintain, it is concerned with vocal function, then certainly its loss would interfere to some extent with vocalization. But there is no such effect to be noted in this instance, the child's voice in no way suffering alteration subsequent to her illness. A study of the principal features of this case teaches us, first, the importance of meeting "the indications" promptly and in a decided manner; and, second, of endeavoring to prevent the occurrence of what is recognized as a fatal complication when it arises,—cardiac paralysis,—by anticipating its onset and guarding against it, so far as may be done, by the use of *strong* doses of that very best of heart tonics in asthenic diseases, strychnine. Having been accustomed to treat all grave cases of diphtheria during the past two years with corrosive sublimate internally, and having saved thereby cases which would certainly have proved fatal under more usual methods of treatment, since I employed it as a *dernier ressort* when "the iron and potassium treatment" had utterly failed to help the patient, I lost no time in using it here. For the first time in my experience with this most valuable remedy was I obliged to discontinue it on account of the ptialism it induced. And lest the criticism be made of its administration in the dose of  $\frac{1}{4}$  grain every two hours, let me state that I always have used it in proportionate doses in every case of the disease. In a recent case of malignant character, where an infant of thirteen months was the patient, I administered  $\frac{1}{4}$  grain every two hours,

increasing it to  $\frac{1}{2}$  grain, as the conditions demanded. The child recovered.

As the necessities of each case we treat must be our guide in the administration of the required remedy, so is it in diphtheria. For a patient suffering with violent pain, we should not think of administering ordinary doses of an anodyne by the mouth, but our first thought would be to control suffering with morphine hypodermically administered, and in such a dose as would meet the requirements of the case. In malignant cases of diphtheria the system shows a tolerance for the bichloride that is surprising, and it can be persisted in without fear so long as the septic conditions demand its continuance. My experience with it has convinced me that it is the remedy on which the greatest reliance may be placed, and when, as in the present instance, its constitutional effects are unfavorably manifested, there must be an idiosyncrasy on the part of the patient explanatory of it.

Obliged to discontinue this remedy, then, to what could I turn but to the iron and chlorate of potassium treatment? The latter was contraindicated on account of the coexistent desquamative nephritis, and if the chloride of iron were to accomplish any good at all, it must be from heroic doses. A tolerance of 15 drops was obtained as a commencing dose, and rapidly increased to 35 drops, every two hours, before the desired change in the patient's condition was noted, and not until several weeks after the entire disappearance of the membrane from the throat was the dosage lessened.

The second point which, in the writer's opinion, should be dwelt on more prominently by the authorities on children's diseases is the necessity for the early administration of strychnine in all cases of severe diphtheria. The two complications which are most to be feared in this disease are diphtheritic laryngitis and paralysis of the heart-muscle. In the former, whenever it may occur, we have the operation of tracheotomy as a possible remedy; in the latter we are utterly powerless when taken by surprise, and nothing can avail to save the life of our patient. Strychnine, however, when early administered and pushed even to the manifestation of its physiological effects, is amply sufficient for this terrible crisis, and has certainly been the means in my hands of averting a fatal termination in not a few instances. In the case under discussion the pulse-rate reached 160 to 170 per minute, and maintained that rapidity for several days, but the heart was all the while under the tonic and sustaining influence of the strychnine, and eventually that run-

away organ was brought under control. In another case of this disease, which terminated fatally from diphtheritic laryngitis eleven days after its seizure with scarlatina maligna (the patient an infant of eighteen months), finding the heart-muscle failing,  $\frac{1}{10}$  grain of strychnine was given, the dose being increased to  $\frac{1}{8}$  grain, until the extended head, rigid in tonic spasm, warned me that the full effect of the drug was obtained at the same time that the danger of cardiac paralysis was overcome; but for the extension of the membrane to the larynx several days later, it would certainly have saved the little patient's life. And not only in diphtheria, but in every instance where the failing pulse evidences the more dangerous condition of a failing heart-muscle, should strychnine in large doses be depended on as the sovereign remedy. In the latter days of typhoid fever, when we find a degenerated heart-muscle weakening under the continued strain of a high temperature, strychnine is especially valuable. In a recent case of this disease I employed it in the dose of  $\frac{1}{10}$  grain every four hours for several days, with the result that my patient, a young man of twenty-eight years, is now in good health, instead of having succumbed to what bade fair to be a fatal collapse when this drug was resorted to. It is true that there was some feeling of uncertainty as to his tolerance of such a dose, and on the third day a fully-developed *risus sardonicus* gave me a hint that I did not fail to act upon.

Together with strychnine as a safeguard against cardiac failure, a rigid observance of absolute rest on the part of the patient must be enforced. The head should not be permitted to be raised from the pillow, and the slightest exertion should be guarded against, not only during the attack, but for as long a time subsequently as the heart action, by its abnormal rapidity or other features, may indicate the need of care and watchfulness. In this way alone may we insure ourselves against possible accident.

What, then, has "the local theory" done for diphtheria? may well be asked. Are there many, like the physicians in charge of the Friederichshain Hospital, of Berlin,\* who, with the courage of conviction, have instituted no drug treatment for the management of diphtheria the past two years? Accepting the local theory in its fullest meaning, *local* treatment only is their cry, let constitutional needs take care of themselves as best they may! "And yet there were sixty-four per cent. of cures," it

is remarked, whether surprisedly or in a commendatory way the reader is permitted to decide for himself. Are there many who will assume such a responsibility as this in defence of theory, and calmly withhold the needed cardiac stimulants from a system debilitated by disease, although they may find local measures powerless to prevent a constitutional infection and all that is entailed thereby? And yet that is the logical outcome of the position taken by the germ theorists to-day, if we are to believe all they would lead us to infer. Their theories are plausible, but when weighed in the balances of actual clinical experiment they are found wanting. How many of the sixty-four per cent. of cures recorded in this disastrous experiment were mild cases and what proportion of the thirty-six per cent. of losses were of malignant character the report does not show; but if this be the result of what a *local treatment only* in diphtheria is able to effect, it can never be satisfactory to him whose efforts are directed towards the employment of the most rational procedures in the never-ending conflict with disease. The writer of this article regards anything beyond a five per cent. mortality in diphtheria as more than he is willing to confess himself responsible for, and responsible only because his utmost efforts, both in the direction of a local and systemic treatment, failed to overcome all the difficulties in the way; while, if he omits those cases of diphtheritic laryngitis from his table of losses, where operative interference was refused by the parents of the child, his mortality would sink to an insignificant figure. During the past two years only one case has proved fatal out of a large number of severe and so-called malignant forms of the disease, a result due almost entirely to the employment of the bichloride of mercury treatment.

As there is no "specific" for the diphtherial poison, we must occasionally meet with cases that will defy our best efforts; yet the battle has not been well fought, the best interests of our little patients have not been loyally upheld by any one who fails to perceive *all* the aspects of each case that comes under his care, and who neglects to guard against every pitfall that lies scattered along the course of this disease. It is a gantlet that must be run by the tottering feet of childhood, in the large majority of cases, and every step of the perilous way should be provided for by the physician, since nature furnishes no defence to these little patients of themselves. And he who is unmindful of the dangers to be met, improvident for the future demands of the system for strong support, will

\* THERAPEUTIC GAZETTE, January, 1894.

surely find that the moment will come when the wearied heart fails for lack of the much-needed stimulant, and another victim will be sacrificed, either through simple failure to protect his charge against possible misfortune, or, worse, through a blind adherence to a theory which contraindicates the employment of internal medication because experimentation has determined that *local* measures alone are compatible with the pathogenesis of this disease!

To sum up the whole matter, there can be, of necessity, *no routine treatment* for the disease. Some cases may require only local measures to arrest the disease, but even in these rest in bed should be insisted upon as of, perhaps, vital import to the patient. Heart-failure is equally possible in the mildest and the severest forms of the disease. One case the writer recalls, where a bright little child complained of "sore throat," but was not thought to be sick enough to be kept in bed by the attending physician, a homœopath, and while at play in the sick-room several days later suddenly died in syncope. The circumstances attending the death of the late Bishop Brooks are of so recent occurrence as to need but brief mention. Suffering from a slight cold and "sore throat," he was not supposed to be in any condition necessitating anxiety until the fatal attack of heart-failure was induced through a prolonged attack of coughing, the weakened cardiac organ, primarily affected by the diphtherial poison, not being able to bear the strain thus brought upon it. Are these examples not amply illustrative of the necessity for rest even in the mildest forms of the disease? And do they not also teach the futility of local measures being depended on to combat the general features of the disease? Is it reasonable to expect that topical applications to the throat are going to favorably affect a weakened heart-muscle, or prevent the catastrophe when the already damaged heart may be called upon for some unexpected exertion, or to withstand some unforeseen burden? Certainly not. If, then, the indications plainly point towards the need of rest in bed, even in mild cases of diphtheria, and the administration of such a heart-tonic as strychnine as a safeguard against heart-failure, when we come to the malignant cases can we in reason refuse to meet the symptoms of general septic infection with their appropriate remedies, and say we shall first destroy the local cause of this outbreak by the proper local treatment, and utterly fail to take note of anything beyond? Local treatment is of value here, as a matter of course, but it must be sup-

plemented by measures designed to overcome the septicæmia occasioned by the local lesion. It is in these cases that the bichloride treatment has been of especial value, accompanied by full doses of alcohol. But where, as in the case reported, mercury cannot be tolerated, then iron in heroic doses must be the dependence, and pushed to the fullest limit of tolerance by the stomach. By such measures as these may we hope to lessen the mortality-rate of this disease, and, unfettered by any blind devotion to a theory, work out the salvation of those intrusted to our care without fear and trembling, but with the fullest prospects of ultimate success.

*WHAT CAN BE DONE IN THE DIAGNOSIS  
AND TREATMENT OF GASTRIC  
DISEASES WITHOUT THE  
USE OF THE STOMACH-  
TUBE?*

---

BY A. L. BENEDICT, A.M., M.D., BUFFALO, N. Y.,  
Lecturer on Digestive Diseases, Buffalo Dental College; Consultant  
in Digestive Diseases, Riverside Hospital.

---

THIS question was brought forcibly to my attention by the remark of a physician who was hesitating before submitting to lavage. "Doctor," said he, "remember that a doctor doesn't like to be hurt." In this sentence, a capital illustration of the fact that a sick physician is not the ideally passive patient whom we like to encounter, was implied the aversion which nearly all patients feel to the use of instrumental or mechanical means of treatment. Objectively considered, the stomach-tube is almost absolutely safe and reliable; its use requires rather the skill of experience and good judgment than manual dexterity; it clears up, by the aid of chemical tests and inspection, the mysteries of a diseased organ; it is a valuable and rational therapeutic agent. From the patient's point of view, however, the passage of the tube is an extremely disagreeable, if not actually painful, procedure; it is more or less shocking to an æsthetic nature, and it is regarded almost as a last resort. The professional and, to an increasing degree, the lay conception of the physician who essays to treat stomach troubles in a modern and scientific fashion, is as an appendage—a very intelligent and important one, no doubt, yet distinctly an appendage—to a long, smooth rubber tube. In regard to the feelings of the patient, I believe that a middle course should be adopted between a weak concurrence with every whim and aversion and an arbitrary demand of absolute compliance with dictates which may be quite as

much whims as any notions of the patient. It is often wiser, after having given our advice conscientiously and clearly, to allow the patient to select a slower route to health or a less radical cure, if the sacrifice, in his opinion, is compensated for by additional comfort or safety or by an important pecuniary or social advantage. It is, at any rate, interesting and profitable to note the limitations to the use of the stomach-tube and, by contrast, the circumstances under which it becomes of paramount value.

The factors to be studied in a diseased stomach are (1) sensation, (2) absorption, (3) motion, (4) secretion, (5) organic changes, (6) foreign elements.

The sensation of the stomach, whether normal or perverted, can, of course, be determined only from the statements or gestures of the patient, although we must discount the overdrawn descriptions of suffering on the part of the hysterical and perhaps add to the phlegmatic utterances of others.

Absorption is estimated by the administration in capsule of .10 to .20 (ten to twenty centigrammes) of potassium iodide, which is quickly dissolved, and is eliminated in the saliva in from eight to fifteen minutes normally. This time includes the delay of melting the capsule, dissolving the salt, its absorption, circulation, and elimination, and the expulsion from the mouth. In order to have as little variation as possible, the following details should be attended to: The capsules must be thin in order to melt quickly;\* they must be freshly filled in order to prevent deliquescence. The patient must swallow the capsule quickly, with a constant quantity of water at a uniform temperature. The outside of the capsule must be free from iodide, and it is well to test the saliva immediately after swallowing to make sure that no iodide has escaped directly into the mouth and that there is none in the system from previous medication. The saliva is taken in test-tubes at three- to five-minute intervals. One or two drops of nitric acid are added to each tube to liberate iodine, and a little starch-paste or dried scale of starch dropped in. The starch forms with iodine a beautiful purple or blue tint,—purple if very little iodide has been eliminated, blue if the reaction is more marked. To save time I

sometimes give patients a set of vaccine vials in their wooden cases, numbered 5, 10, 15 to 30 (minutes), and have the saliva brought to me for the tests.

The motor power of the stomach, or rather the peristaltic movement which empties the viscus, is tested by administering salol, which remains unchanged in the acid juice of the stomach, but is decomposed into its salicylic and carbolic constituents in the alkaline secretion of the small intestine. Thence the salicylic acid is absorbed; it passes through the portal, pulmonary, and aortic circulation, reaches the kidneys, and is eliminated in the urine. This process, like that of the iodide test, is complex, yet so rapidly are the vital functions performed that salicylic acid is found in the urine long before the bulk of the stomach contents have passed through into the intestine. Therefore, notwithstanding the delay of overcoming the acidity of the chyme in the duodenum and the devious course from intestine to bladder, the test represents the first leaking through the pylorus. The salol is given in powder or wafer with the last mouthfuls of the meal. Usually a gramme is given, but this dose has caused death in one instance, and I have found fifty centigrammes sufficient. To prevent too great dilution I direct that the urine be passed immediately after the meal and thrown away. The urine should then be saved forty-five minutes, one hour, one hour and a quarter, two hours, and three hours after the meal. With the 50-centigramme dose of salol salicylic acid is found occasionally in the forty-five minute samples, in the majority of the hour samples, almost always in the hour and a quarter samples. The urine passed from two to three hours after a meal usually gives the most marked test, thus supporting the old idea that two or three hours is the time to be allowed for gastric digestion in estimating the intervals of feeding with light diet or in administering remedies designed to act particularly on the intestine.

Although experimentation by Ewald and others has shown that one hour and a quarter is the extreme normal limit of delay in the excretion of salicylic acid, it has not been proved that the delay is due solely to insufficient gastric peristalsis. Huber has proposed to modify the test by determining the time at which salicylic acid finally disappears, and he considers that if it is found more than twenty-four hours after the meal with which one gramme of salol is taken, the stomach is deficient in motor power. Yet in a case of non-acid dyspepsia in which salicylic acid appeared in the urine only

\* I was recently furnished with capsules which required twenty-five minutes to melt. To guard against error from this source, it is well to make a control test in lukewarm water, coincident with the experiment on the patient.

half an hour after the meal at which fifty centigrammes of salol were given, I found the same reaction in several samples of urine voided at various times up to forty-eight hours. Here were contradictory results, which I would explain on the ground of insufficient intestinal absorption or of some delay in elimination. The case was cured by attention to the general health and by supplying the needed hydrochloric acid for a week or two.

The test for salicylic acid is very simple. To the urine in a test-tube or in an ordinary vessel add, drop by drop, a solution of ferric chloride. The tincture will prove satisfactory, though the liquor is usually recommended. The principal source of error consists in adding too much ferric chloride. In the presence of salicylic acid a cloudiness and then a purplish-red color develops.

Some idea of the motor power of the stomach may be gained from the general musculature and energy of the patient, but the inferences may be fallacious.

The tube affords comparatively little information as to the movements of the stomach. One patient may force a jet of water out of the stomach, through the tube and across the room, while another may be unable, even though retching violently, to do more than alter the level of fluid in the funnel. The natural inference is that the former is strong, the latter weak, in his gastric muscles, but nervous excitability, reflex contraction, and the auxiliary abdominal and diaphragmatic compression have much to do with the phenomenon, and, after all, the throwing of a jet of water is only an athletic feat of the stomach and no guarantee that its normal work will be properly performed.

Klemperer has proposed to introduce a hundred cubic centimetres of pure olive oil into the stomach, and, after two hours, to siphon away what remains and compare the diminution in volume with a standard. Klemperer himself admits the inconvenience of this method, and it would seem impossible to rely on getting any positive results from the use of so small a quantity of fluid, which, nevertheless, is twice the usual purgative dose of olive oil. I have several times heard watery solutions rushing through the duodenum during lavage, and have removed much less than was introduced. In one case I kept a record of the amounts of water used so as to determine the loss. In each instance the water was siphoned away as soon and as thoroughly as possible, and thus loss by absorption was reduced to the minimum.

### *Lavage Six and a Half Hours after Eating.*

Introduced. Cubic centimetres.	Removed. Cubic centimetres.
1200	600
1600	1150
1400	1250
1400	400
200 (stoppage by raisin dis- lodged by the 200 cubic centimetres).	750
5800	4150 = 1650 cubic centimetres lost.

### *Lavage Two Hours after Breakfast of Piece of Bread.*

Introduced. Cubic centimetres.	Removed. Cubic centimetres.
1600	1175
1400	1200
1600	1400
1600	1400
1600	675
400	900
400	650
400	350
400	400
9400	8150 = 1350 cubic centimetres.

### *Lavage; Stomach Empty.*

Introduced. Cubic centimetres.	Removed. Cubic centimetres.
1300	1150
1600	1100
2000	1600
1600	1400
400	325
6900	5575 = 1325 cubic centimetres.

The conclusion is, that during the course of ordinary lavage in a person with only functional trouble, about fifteen hundred cubic centimetres of water were lost, doubtless partly by absorption, but largely by passage into the intestine. Now, while the olive oil would be practically unabsorbable from the stomach, its stimulant action on peristalsis would be relatively greater than that of water, and we would expect most of so small a volume as one hundred cubic centimetres to disappear in the course of two hours. However, it must be admitted that, if in any given case a considerable quantity of the oil could be recovered after two hours, it would be the best possible proof that the stomach was deficient in motor power. Unfortunately, the converse does not hold good, for we should expect even an inactive stomach to get rid of one hundred cubic centimetres of a fluid used elsewhere in therapeutics for the stimulation of peristalsis.

The conclusion seems obvious that the stomach-tube is practically useless for deter-

mining the motion as well as the sensation and absorption of the stomach, except that the chemical examination of the stomach contents assists in determining the motor and absorptive power. It is in the investigation of the remaining functions of the stomach,—the secretions and the course of digestion,—that the tube becomes important. It is a truism that chemical processes can be determined only by chemical tests. The alternative confronts us, therefore, of proceeding by guess-work or of obtaining a portion of the stomach contents for analysis. We may get a sample of chyme by inducing vomiting, by having the stomach-bucket or sponge swallowed and withdrawn, or by expression and suction through the stomach-tube. Of these means, the use of the tube is by far the least distasteful and the most practical. Still, in weak patients with irritable stomachs, who vomit frequently, we may avail ourselves of the stomach contents accidentally furnished and avoid the use of the tube.

Günzburg has proposed to estimate the rapidity of albuminoid digestion without recourse to the tube, by giving 10 to 20 centigrammes of potassium iodide in a closed gelatin capsule or in a small piece of rubber-dam tied with fibrin. When the gelatin or fibrin is digested, the iodide is liberated and then absorbed, and eliminated in the saliva. Günzburg's test, however, is like an equation with three unknown quantities. Finding iodine in the saliva tells us that the fibrin or gelatin has been digested and the iodide absorbed. But we do not know how much time has been consumed in absorption, nor how much hydrochloric acid there is in the stomach, nor what proportion of the albuminoids ingested has been converted into propeptone and peptone. Very often the filtered stomach contents, an hour or an hour and a half after eating, will contain a mere trace of albumin and propeptone and an abundance of peptone. So far the examination would indicate perfect digestion, but further tests and inspection will show an absence of hydrochloric acid and unchanged pieces of meat. The digestion of a thin film of gelatin or of a fibrin thread is no guarantee that there is enough acid left for the digestion of ordinary proteid foods. Thus, while Günzburg's test may give a fairly good general idea of the course of albuminoid digestion, it is neither analytical nor reliable.

Fats and carbohydrates are, in one sense, foreign elements in the stomach, since they are not digested by the gastric secretions. Sugars, being soluble, are normally absorbed from the stomach within an hour. Starch, whose cellulose has been ruptured by cooking, should be

digested by ptyalin in the stomach, also in the course of an hour, and the glucose resulting should be absorbed as soon as it is formed. The statement so often made that no starch should be found in the stomach contents more than an hour or so after eating applies to the standard meals of meat and cooked starch, but does not apply in cases in which bananas or any other form of raw starch has been taken. Raw starch must, of course, remain such until the stomach empties itself into the intestine.

Although I have said that our ideas of gastric secretion and digestion are reached by guess-work, unless we obtain a portion of the stomach contents and subject it to analysis, a little consideration will show that the word *guess-work* is used in no invidious sense, for, until the last few years, there was no other means of knowing the condition of the stomach, and there are few deeply-situated organs whose diseases we can even now diagnose except by inductive reasoning from present symptoms to pathological states previously observed post mortem. The questions which we aim to answer by chemical examination of the stomach contents are, in brief, these: 1. Are the fats and carbohydrates innocuous, or are they fermenting? 2. Are cooked starches changed into absorbable grape-sugar as rapidly as normal? 3. Are the three secretions of the stomach—rennet, pepsin, and hydrochloric acid—present in proper amounts, and do they properly digest albuminoids into peptone?

The first question is answered unfavorably by finding bacteria and yeasts microscopically and butyric and acetic acids chemically in the stomach contents. But, knowing that fatty and starchy substances have been taken, that certain foods of these classes habitually cause trouble, finding the stomach tympanitic with gas, and noting the eructation of sour gas or liquid, in which we may smell butyric and acetic acids, the diagnosis of fermentation is quite as well established.

The second question—as to the change of cooked starch into sugar—is not in itself an important one. If the pancreas can provide for any reasonable quantity of raw starch, it will probably not be overtaxed if the salivary function also devolves upon it. If the saliva is suspected of being at fault, let the patient chew a bit of raw potato, and spit into a test-tube, in which, after a few minutes, the ordinary sugar test will show whether or not enough ptyalin is secreted. Ewald's experiments have failed to find a single case of salivary incompetency even in patients with advanced dental caries or malignant disease of the mouth.

Failure of starch digestion in the stomach signifies, therefore, inhibition by some abnormal factor, which in most cases is an excess of hydrochloric acid or the presence of acid fermentation, both of which are included in the other two questions.

The third question—referring to the three secretions of the stomach—is the most important, but even this can be narrowed down in practice. Rennet is a substance of which we know almost nothing of practical importance. Ewald barely alludes to it, and his translator, Manges, sums up the researches of Raudnitz, Boas, Johnson, Klemperer, and Rosenthal in one sentence: "The result of these investigations is that rennet, like pepsin, is a constant constituent of the gastric juice, its absence indicates atrophy of the gastric mucosa; otherwise it has no practical significance." Quite frequently in infants, and occasionally in adults, there is noticed a tendency to the formation of large, hard curds from milk foods. I have in mind a woman aged forty, who vomited curds as large as butternuts, and with the toughness and peculiar agreeable odor of artificially prepared cheese-curd. This case was treated by temporarily withdrawing milk from the diet. I know of no means of determining clinically the exact excess of rennet—if, indeed, the question is a quantitative one—nor of directly modifying its secretion. Certainly the stomach-tube would have been useless to remove such large, hard masses.

Pepsin, like rennet, is an organic but unorganized ferment, a little of which seems to act as well as a good deal. It is almost always present in the stomach, and therefore it is rarely necessary to test for it. It likewise follows that its administration should be equally rare, but the great commercial value of pepsin shows how little this physiological principle is carried out in practice. Pepsin is the trump-card of a number of leading manufacturing pharmacists: their agents, so far as I can judge, are genuinely surprised to find a physician who uses pepsin in only two or three cases a year. Certainly, if the wholesale drug-houses had any fears as to the salability of pepsin, they would have it indorsed by those prominent physicians, who stand ready at all times to obtain successful results from new drugs, in blocks of twenty-five assorted cases. To give force to my own protest against the indiscriminate use of pepsin and to justify the suggestion that we may usually disregard it, let me call two witnesses. Ewald says, "To-day we know that pepsin is present in a very large number of cases, even when free hydrochloric acid is ab-

sent. . . . We should, therefore, restrict its administration to those cases in which its absence can be actually proved,—that is, to cases of advanced mucous catarrh and of atrophy." A. Lockhart Gillespie, of Edinburgh, in an article in the *International Medical Magazine* of October, 1893, expresses himself thus: "The determination of the presence of pepsin need be done only in very exceptional cases. Pepsin is rarely absent from the stomach contents. The amount of quackery indulged in in the prescribing of pepsin preparations is marvellous."

The conclusion seems obvious that the most important fact to be determined in the investigation of the gastric chemistry is the quantity of hydrochloric acid. It is even possible to classify the organic diseases according to the increase or diminution of this secretion. Gastritis of all grades, carcinoma, and usually dilatation are marked by a downward tendency in the secretion of this acid; ulcer by a marked increase.

Acute gastritis means corrosion of the stomach, either by hot water or some similar traumatism, or by an active poison. So far as the gastritis itself is concerned, the stomach-tube is clearly contraindicated. Although the old-fashioned stomach-pump is popularly associated with stories of poisoning, any form of tube is likely to become clogged, and the poison is usually best ejected by inducing vomiting. The comparatively rare cases in which narcotism prevents the action of emetics, or in which there may be a question whether the weakened stomach-wall would not be less strained by siphonage than by the act of vomiting, will not be discussed here. Subacute gastritis can scarcely ever require the tube, either for diagnosis or treatment, unless it is excited by foul fermenting soft masses. Chronic gastritis can usually be diagnosed from the state of the circulation and the history of the case; still the tube is desirable in order to verify the diagnosis, and is invaluable for treatment. Copious hot alkaline drinks taken before meals are of some service in stimulating the sluggish circulation and in washing away the tenacious mucus which dams up the feeble secretion of the glands, but one experience with lavage will teach us that the stomach must be filled and emptied several times before it is properly cleansed. Lavage with menthol vapor I have described in previous papers, and, although it would be egotistical to claim more than a further trial of this mode of treatment, it has seemed to do good in a number of cases of catarrh of the stomach.

Dilatation of the stomach can be diagnosed without the aid of the tube, although the alternation of tympany and flatness and the metallic tinkle of bubbles bursting in the half-filled stomach are valuable tests, possible only when the tube is used. In the treatment, the tube is almost indispensable to relieve the concomitant catarrh and to remove undigested remnants of food. Still, much good may be accomplished by giving predigested foods and antiseptics.

In cancer the continued absence of hydrochloric acid, as determined from the analysis of the gastric contents, is diagnostic but not pathognomonic, as was at first claimed. Few cases of cancer fail to present other indications of their nature, and, without confirmatory evidence, the non-acidity would scarcely warrant a positive diagnosis. Yet there are cases in which every hint as to the true condition must be eagerly sought. All treatment, except possibly operative, is palliative, yet the tube is useful for the treatment of the accompanying catarrh and fermentation. However, there comes a time when any mechanical interference is dangerous.

Subacidity, or occasionally non-acidity, is the usual condition in what may be termed, loosely, atonic dyspepsias. Yet, in the same day, two young married women consulted me, giving almost identical histories of gastric disturbance. One case proved to have a sufficient secretion of acid, the other almost none. Under different treatment both cases were relieved, showing that the conditions were essentially different. Thus it must be borne in mind that, although eighty or ninety per cent. of our dyspepsia cases will be relieved by the administration of hydrochloric acid, in each particular case we run a corresponding risk of ten or twenty per cent. of giving inappropriate treatment unless we examine the stomach contents.

Moreover, there is an acid neurosis, which we in Buffalo should never forget, since its clinical picture is so largely the delineation of our fellow-member, Professor Charles G. Stockton. This condition of supersecretion of hydrochloric acid may be suspected from the occurrence of dyspepsia in a neurotic individual, from the account of sharp gastric pain temporarily relieved by taking food, from highly acid eructations, and from the general characteristics of a state of over-excitement rather than depression of an organ. Still, the diagnosis needs the confirmation of chemical examination. The same neurosis culminates in peptic ulcer. The occurrence of a large hemorrhage scarcely needs the assistance of the tube to es-

tablish the diagnosis, and the treatment both of the neurosis and of the organic lesion consists of physiological rest of the stomach and such remedies as shall calm the overwrought secretory nerves. Ewald dismisses the question of using the stomach-tube in gastric ulcer with these words: "I refrain from introducing the tube in all cases of ulcer in which the diagnosis can be made in another way, and I do so, so much the more, since in these cases the examination of the stomach contents does not establish the diagnosis and since it does not aid us in the treatment."

In this review of well-known methods of diagnosis and treatment, the stand-point has been assumed of one who for some reason does not wish to use the stomach-tube. This reason may be excellent or it may be the poorest kind of an excuse. Do not understand me as deprecating the use of one of our most valuable aids to diagnosis and treatment, because I have endeavored to show how far it is unnecessary and how well we may diagnose and treat gastric diseases when some emergency or obstacle deprives us of this aid.

#### *LAVAGE IN THE TREATMENT OF GASTRIC DISORDERS, ESPECIALLY IN DISPENSARY PRACTICE.*

By JULIUS L. SALINGER, M.D.,

Lecturer on Renal Diseases in the Jefferson Medical College;  
Chief of the Medical Clinic, Jefferson Medical College  
Hospital; Physician to the Philadelphia  
Hospital, etc.

THE mechanical treatment of diseases of the stomach is of very ancient origin. The Greeks were familiar with several methods of artificially evacuating the stomach. During the Roman empire a number of appliances had been invented to produce emesis. Among the most familiar ones was the vomiting feather of Pinna. Another equally well known instrument was the digitale vomitorium, a piece of soft leather, shaped like a finger, one end remaining open so that it could admit the finger, the other end stuffed with wool, being about ten to twelve inches in length. This was introduced into the pharynx and part of the oesophagus, and vomiting promptly followed. In the eighteenth century elastic catheters were used to introduce food and medicaments into the stomach. This was, perhaps, the origin of the stomach-tube. Hunter was familiar with this procedure. Bush, an English surgeon, was the first to actually use the stomach-tube, and he may be termed the inventor. In a case of opium-poisoning he inserted a long elastic tube

into the oesophagus and stomach, filled the stomach with water, then attached an ordinary syringe and pumped out the diluted contents. In the early part of the present century a number of instruments were invented by Jukes, Ward, Read, and others to serve as stomach-pumps. These appliances were, however, never in general use. It remained for Kussmaul, in 1867, to call attention to the treatment of gastrectases by lavage, and to again introduce the use of the stomach-pump and tube. Since that time numerous other uses have been found for the stomach-pump as well in diagnosis as in treatment, and many additions have been made to our literature, in which the mechanical treatment of the stomach has received the attention that it merited. (Leube, "Die Magensonde," Erlangen, 1879.)

The instrument now generally employed in lavage consists of a soft-rubber tube (about No. 32 of the French scale) with a funnel-shaped arrangement at the top to facilitate the introduction of liquids. Plain water, preferably lukewarm, is all that is usually required, although antiseptic antifermentative substances of all kinds have their special indications, such as salol, boracic acid, hydrogen peroxide, etc.

The method of using the tube is quite easy. The patient is told to open his mouth as wide as possible, the tube is placed over the base of the tongue into the pharynx, and he is told to swallow; while deglutition is going on, the tube is speedily, though gently, pushed down the oesophagus into the stomach. About eighteen to twenty inches is all that is generally required, and usually the tube has a circle marked upon it to indicate that it has entered the stomach. The patient soon becomes accustomed to the operation, and after the first or second trial it gives him no further inconvenience. In nervous or irritable patients the throat may be painted with a four-per-cent. solution of cocaine before using the tube. A dose of 30 grains of potassium bromide on the night previous to the morning on which the tube is to be used has proved of great value in the writer's hands to check the irritability of the throat and the general nervous manifestations of patients undergoing treatment by lavage.

Before using the tube the patient's throat should be carefully inspected. Stenosis of the pharynx, due to large hypertrophied tonsils, tumors, and cicatrices, may be absolute mechanical hinderances to the introduction of the stomach-tube. Never, under any circumstances, should force be used. Examination of the organs of respiration and circulation is

also necessary. Valvular disease of the heart, aneurisms, especially of the aorta, large pulmonary cavities, acute and chronic catarrh of the larynx, are contraindications to the use of the tube. In some instances symptoms of laryngismus stridulus and fatal syncope have been reported where these conditions have been overlooked.

The advantages of the use of a soft elastic tube over a hard and unpliant instrument are obvious. No injury to the soft parts of the oesophagus or stomach can result from the use of a soft instrument. Blood has never been noticed in the washings, as frequently occurred where a hard and stiff instrument has been employed. The soft tube is more durable and less liable to break than the gutta-percha sound (the ordinary hard instrument used). The soft tube also has some disadvantages. There are cases, especially in irritable patients, in which the tube, upon its introduction into the pharynx, readily curves and bends. In such instances the use of the soft tube is almost impossible without the assistance of a local anæsthetic (cocaine). With ordinary care there is little or no danger of entering the larynx with the stomach-tube.

The stomach-pump is now rarely employed, the tube taking its place for all practical purposes. The indications for lavage are twofold: first, as to diagnosis; secondly, as to treatment.

For diagnostic purposes, lavage is of use to determine the quality and quantity of the gastric juice. The quantity of fluid that the stomach will contain can be accurately determined by pouring in a known quantity of water and filling the stomach to its fullest extent. Thus a positive diagnosis of dilatation of the stomach may be made. A test-meal may be given, and after a certain time the stomach may be washed out and the progress of digestion conclusively ascertained. By an examination of the gastric juice by means of chemical tests the presence or absence of normal or abnormal acids, pepsin, and other ferments may be detected. The relation which the gastric juice bears to normal or pathological conditions of the stomach is too well known to require further elucidation.

The most important use of lavage is, however, from its therapeutic stand-point. This mechanical treatment has for its object the elimination of injurious or toxic agents, be they introduced as such or afterwards undergoing such changes in the system as may render them harmful. The diseased mucous membrane of the stomach is directly treated, and

the diminished or lost contractibility of the stomach is favorably influenced. Lavage may, then, be employed in cases of poisoning, either alkaloidal or mineral, in acute or chronic gastritis, and especially in cases of dilatation of the stomach. It is also of decided use in the treatment of peptic or round ulcer of the stomach, in all varieties of pyrosis, cardialgia, and malignant disease of the stomach. Its employment in carcinoma of the stomach is beneficial from the fact that such disease is mostly situated at the pyloric extremity of the stomach, and by its narrowing of this orifice gastrectasis results.

It is the object of this paper to call attention to the treatment of gastric diseases by lavage in dispensary practice. Seventy-four cases in all were treated during a period of four months, from September to January. They were cases of gastric derangement, presenting general dyspeptic symptoms, such as constipation, pyrosis, headache, etc., in which the usual remedies generally prescribed had proved ineffectual. The patients with alcoholic histories were separated from the non-alcoholic. Of the total number, forty admitted the excessive use of intoxicating liquors; two were cases of gastric cancer; three had cirrhosis of the liver, with marked gastric involvement.

In all the cases (seventy-four) so treated, failure to introduce the tube occurred in but seven, and in most of these the fear of having a foreign body thrust down their throat was the principal cause of the failure. No medicine was given, the treatment depending entirely upon lavage. In none were any bad results observed due to the use of the tube. The results may be briefly stated as follows: marked improvement resulted in fifty-two, some improvement resulted in eight, no improvement resulted in four; three cases did not return for treatment.

The most marked results occurred in the patients with alcoholic histories. The acid eructations, the flatulency, the oppression in the gastric region, and in many the obstinate constipation were relieved from the beginning. The improvement was so noticeable that the patients would come and frequently ask for a repetition of the treatment. Quite as gratifying temporary results were obtained in the cases of malignant disease of the pylorus. The history of one of the patients is quite interesting, and a brief account may be here given:

Patient—man aged fifty-seven—had for four months complained of pain in the epigastrium, which had gradually increased in severity. About the same time, vomiting, usually occur-

ring about two hours after meals, had manifested itself. The vomited matter consisted of the food that the patient had taken, in a state of more or less active fermentation. Only once had "coffee-ground" vomit appeared, and that at about the third month of the duration of the illness. The patient had lost thirty-two pounds in weight, was markedly emaciated, and somewhat cachectic. On physical examination, the heart and lungs were found normal, and on palpation of the abdomen a tumor was noticed about the size of a large lemon, occupying the position of the pylorus, exceedingly tender upon even slight pressure. The tumor was not movable upon manipulation. The patient had only within a week noticed the tumor. He was given a test-meal, and free HCl could not be demonstrated by any of the accepted tests. His urine showed nothing abnormal. His temperature, taken at different intervals on succeeding days, showed a slight subnormal tendency,—97.5° to 98° F. A diagnosis of malignant disease of the pylorus was made and lavage ordered. It was found that the stomach would retain with ease five pints of water, although this quantity of fluid produced slight pain. The patient had in all thirty-four washings. He was benefited from the first lavage, the urgent symptoms of which he complained being almost entirely removed, such as cardialgia, pyrosis, flatulency, vomiting, etc. He returned one morning, saying that he considered himself well and did not require further treatment. After an absence of six weeks from the clinic, he again presented himself, with the reappearance of his former symptoms, and urgently begged for treatment.

This case is only mentioned to show what relief, although only of a temporary character, can be obtained in malignant disease. It is easily understood how, in cases of malignant pyloric disease with stenosis, and consequent dilatation of the stomach with gastric catarrh, good results are obtained by lavage. The majority of the symptoms occasioned by malignant gastric disease are due to the dilatation of the stomach with the associated gastric catarrh, and in these conditions lavage is the remedy *per se*.

Beneficial results were also obtained in cirrhosis of the liver with secondary gastric manifestations.

When the character of the ordinary dispensary patient is considered, the lack of proper hygiene, the want of a necessary diet, their inability or unwillingness to abstain from restricted diet, their usual alcoholic tendency, the results obtained by lavage in the medical

clinic of the Jefferson Medical College Hospital are quite creditable.

Where the physician has the absolute control of his patient, as in bedside, hospital, or private practice, the result in treatment is much better. In none of the cases have harmful results followed, and where the caution is employed that has been mentioned in detail above, no evil effects will follow. In many cases in private practice the patient soon learns the manœuvre himself, and many physicians can cite examples of patients that regularly carry out this procedure without their attending medical adviser.

The therapeutic uses of the tube are many. In cases of poisoning, either alkaloidal or mineral, lavage should be used. In acute or chronic gastric catarrh with subsequent gastrectasis, it will be found by far the best remedy. In peptic ulcer, cardialgia, all forms of dyspepsia, reflex vomiting, no remedy has shown itself so generally useful. In carcinoma of the pylorus with stenosis and consequent dilatation and gastric catarrh, lavage, for a time at least, produces wonderful results. It has been advised recently as a remedy for chronic constipation due to paresis of the muscular coat of the bowel.

The contraindications are few, and it certainly is a remedy that every physician should have at his command, so that its use should give the patient the benefit which so often follows the employment of systematic lavage.

#### *THE TREATMENT OF FRACTURES OF THE SHAFT OF THE FEMUR.*

READ BEFORE THE SECTION OF SURGERY, AMERICAN MEDICAL ASSOCIATION, SAN FRANCISCO, CAL., JUNE, 1894.

By LLEWELLYN ELIOT, A.M., M.D.,  
Surgeon to Eastern Dispensary; Consultant to St. Ann's  
Infant Asylum, etc., Washington, D. C.

OUR chairman having paid the high compliment of assigning the subject of "The Treatment of Fractures of the Shaft of the Femur" to me, I shall, within the time allotted, place my views before the Section in the briefest possible manner.

The causes, the symptoms, and the diagnosis of fracture of the femur being entirely foreign to my subject, no mention will be made of them. We shall likewise exclude from consideration all fractures of the femur not located between the lesser trochanter and the condyles. Although every variety of fracture is found in this bone, the transverse and the oblique are the most frequent; these fractures may be either simple, comminuted, or compound.

Having made our diagnosis, we must have the patient's bed arranged so as to allow permanent and continuous traction to be employed. This traction, in the case of adults, may be effected, after the proper adjustment of the fractured ends of the bone, through the employment of the apparatus of either Liston, Desault, MacIntyre, Thomas, the Smith anterior, the Hodgen suspension, Buck, Boyer, Neill, or the double inclined plane of Esmarch, Gross, or others, the foot of the bed being raised so as to insure counter-extension. In infants either Hamilton's apparatus or vertical extension will give satisfactory results. To enter into a description of the various devices employed in the treatment of fractures of the femur would be of no interest to you, since all are familiar with them. The employment of permanent dressings—plaster of Paris, silicate of sodium, and others of a like nature—I do not think justifiable before the third week, when union is sufficiently strong to warrant their application, although many surgeons employ them from the start, and I would hesitate quite a while before I would use any of them previous to the establishment of union of the fragments. Objections will readily present themselves. Should a compound fracture present itself, I should be still slower in applying a permanent dressing.

The questions of suturing or pegging fragments in cases of compound fracture and of amputation may be settled in a few words. Where the fragments can be properly and accurately adjusted, and the blood-supply to the limb remains good, the fragments should be sutured or pegged, and the wound treated by the open method. When, however, the soft parts are lacerated and the vessels supplying the limb are divided, amputation should be resorted to early, before the patient's strength is wasted through secondary hemorrhage, gangrene, or other causes.

The treatment of fractures of the shaft of the femur resolves itself into the following: A suitable bed, accurate apposition of the fragments, the proper application of the splint and extension, good, nutritious food, and, unless the case is one requiring amputation, the results will generally be satisfactory, although shortening occurs in very many cases.

There is one question in relation to extension in fractures of the femur to which I would like to call attention; it is the matter of the priority of the application of adhesive plaster in extension. The generally-accepted opinion is that Dr. J. K. Swift is entitled to the credit of first using it, and Professor S. D. Gross, in

his "The Anatomy, Physiology, and Diseases of the Bones and Joints," page 50, published in 1830, puts forth his claim as follows: "In complicated fractures of the leg, it not infrequently happens that the soft parts about the ankle are so much contused, or otherwise injured, as to render it impossible to employ the usual extending bands. When this is found to be the case, the difficulty may usually be remedied by applying along each side of the leg, as high up as the seat of fracture will admit, a piece of strong muslin, about two feet and a half in length, two inches and a half in width, and spread at one of its extremities with adhesive plaster. The part which is applied upon the limb should be confined by three or four circular strips, so as to keep it firmly in its place and equalize the extending power. The free extremities of the extending bands should then be tied under the sole of the foot, and be secured to the block or bar which connects the lower ends of the splints. This mode of making extension, for which we are indebted to the ingenuity of my friend and preceptor, Dr. Swift, of this place, will, I am fully persuaded, be found highly useful in practice, and satisfactorily obviate the inconveniences to which I have just alluded."

Now, for more than twenty years I have endeavored to adduce evidence so as to accord the credit to Dr. Alexander McWilliams, of this city, and to that end have searched books and journals and papers. At the time when success seemed to crown this research, I find published evidence which dissipates all contention. The following appears in "Medical and Chirurgical Observations as an Appendix to a former Publication, by Benjamin Gooch, Surgeon, London," page 108, published about 1780: "To answer the same purpose, I have confined one end of a strong strip of sticking-plaster, of a suitable length and breadth, under a circular piece of the same about the middle of the sole of the foot, carrying it over the heel up the leg and confining the other end above the calf with another circular plaster, first gently and gradually bringing down the Muscul. Gastrocnem. as far as they will readily yield; giving the limb, at the same time, the position described in my Treatise on wounds. On the like occasion, I have also fixt one strap by the circular about the foot, and another by that above the calf of the leg, passing the one through a slit in the other, and using them as the uniting bandages; but then two more circulars are requisite to confine the other ends of the longitudinal straps securely." That the studies and this publication of Gooch

did not receive attention from surgeons and other writers is evident from the fact of so many others afterwards working in the same line of thought, each unconscious of the work of the other. Among these workers was Dr. Alexander McWilliams, who treated, in 1827, a case of fracture of the femur by this method of extension at the Washington Almshouse. Failing to establish the claim of Dr. McWilliams to priority in the application of the idea of extension by means of strips of adhesive plaster, I will present such evidence as I possess, all derived from letters in my possession, to establish his claim to the credit of being the first surgeon in the United States to put into practice this idea. At that time (1827), according to the letter of Dr. Hall, the recognized surgeons of this country knew nothing of this method, and, indeed, as late as 1836, M. Larrey mentions the method only to condemn it, as will be seen in the extract taken from the minutes of the Société Royale de Médecine of June 21, 1836.

In a letter, under date of January 9, 1875, Dr. Noble Young, of this city, writes, "In regard to the matter of the invention and application of adhesive strips for the purposes of extension in cases of fracture of the femur, by the late Dr. Alexander McWilliams, I have to state it is within the recollection of his family that it occurred prior to 1829; they know this by circumstances impressing it indelibly upon their memory. He sent a model explaining the application to Paris by Dr. Hall, brother of the late David A. Hall, and received a letter from the French Academy of Medicine congratulating him and thanking him for his valuable contribution. This letter has been mislaid only within the last few years. I may add that Dr. Jos. Borrows remembers its application at the almshouse in this city before 1828, when he was a student there."

Dr. James C. Hall, under date of February 15, 1878, writes, "My evidence as to the application of adhesive strips as a means of extension in the treatment of fractures by Dr. McWilliams must be circumstantial. I came to Washington in October, 1828. After graduating (1827), I was for one year a resident physician and surgeon in the Philadelphia Almshouse, now Blockley Hospital. The visiting surgeons and clinical lecturers were Professors Gibson, Horner, Rhea, Barton, and Harlan. Very many and all kinds of fractures were treated in the House, and I am positive that I never heard McWilliams's mode either mentioned or practised during my term of service. . . . My recollection is almost positive

that my first knowledge of Dr. McWilliams's use of the strips as a means of extension was derived from an article which the doctor published in a newspaper here. I thought it was the *National Intelligencer*, but Dr. Toner has searched for it and not found it there. This has not weakened my conviction that Dr. McWilliams published in some paper an account of his method of treating fractures of the femur. . . ."

Dr. Joseph Borrows, under date of June 6, 1878, writes, "Excuse my apparent neglect in not answering until now your letter in reference to the use of adhesive plaster for the purpose of applying extension in fractures of the lower extremities.

"In the year 1827 I was one of the resident students in the Washington Asylum or Almshouse, of which Dr. Alexander McWilliams was the attending physician. Dr. McWilliams at that time exhibited and used adhesive plaster for the purpose above mentioned."

In the *Archives Générales de Médecine*, Book ii. p. 247, 1836, I find (Société Royale de Médecine, Paris, séance du 21 Juin), "Rapport de M. Larray sur un appareil à extension continue pour les fractures des extrémités inférieures; par le Docteur Williams de Washington.—Cet appareil est une copie à-peu-près entière de l'appareil de Boyer. La seule différence consiste dans une attelle interne qui se fixe à la traverse sur laquelle la vis s'appuie. M. Larray blâme la méthode en général et tous les appareils qui s'y rattachent. Il n'adopte pas davantage le double plan incliné et préfère toujours son appareil inamovible. . . ."

Dr. B. Trautman, of Philadelphia, Pa., at my request, called upon Professor Gross, asking him for some definite date of Dr. Swift's application of this method of extension, and he writes, under date of June 27, 1879, "I called on Dr. Gross several times, but he always happened to be out of town; but last week I called again and saw him. He told me that Dr. Swift employed adhesive plaster in complicated fractures first in 1829."

The record of the almshouse shows, in the morning report of July 18, 1827: "Admitted P. Brady, forty years; report of July 21, 1827, fracture of femur." This is evidently one of the cases to which Dr. Joseph Borrows refers in his letter.

In no work on surgery of this date (1827 to 1836) have I found any reference to this method of extension, so it is very evident that there had been no published development of the idea until Dr. McWilliams sent his model, a doll-baby with the apparatus applied, to Paris. Dr. J. F.

May was present at the presentation and verbally testified to the favorable reception accorded it.

To my satisfaction I have established the following facts:

1. Dr. Gooch was the first to employ adhesive plaster as a means of extension in fractures.
2. The idea was allowed to pass into oblivion.
3. Dr. Alexander McWilliams, of Washington City, was entirely ignorant of the work of Dr. Gooch.
4. Dr. Alexander McWilliams developed and put in practice the idea in 1827.
5. The claim for Dr. Swift is too vague to carry weight with it.
6. The published report of the Société Royale de Médecine is the first published account of the method after its revival by Dr. McWilliams.

1106 P STREET N. W.

#### THE TREATMENT OF PLEURITIC EFFUSIONS.

READ BEFORE A MEETING OF THE PHILADELPHIA CHAPTER OF THE ALUMNI ASSOCIATION OF THE JEFFERSON MEDICAL COLLEGE, HELD MARCH 13, 1894.

BY THOMAS G. ASHTON, M.D.,  
Chief of the Out-Patient Medical Department in the Jefferson Medical College Hospital and Demonstrator of Clinical Medicine in the Jefferson Medical College.

IT is my purpose in this paper to mention a few especial plans of treatment of pleuritic effusions rather than to give a detailed and systematic description of the various methods of treatment of the condition.

In taking up this subject one is at the outset confronted by the fact that the tendency of the day is to assign to one particular organism a pre-eminent position in the etiology of diseases of the pleura. That most cases of pleurisy are of tubercular origin is a theory the truth of which is substantiated by new facts almost every day, but we are in danger of losing sight of the fact that agencies other than the tubercle-bacillus hold important causal relations to the disease under consideration.

This tendency to give to the tubercle-bacillus chief place in the etiology of pleurisy has naturally resulted in limiting the therapeutic management of the disease, and as we have but one cause, so we are inclined to restrict ourselves to but one treatment.

Churton (*International Clinics*, Philadelphia, 1891, vol. iii.) remarks, "There is no apparent reason why there should not be as many different causes for disorder of the cell-plates, and consequent effusion into the pleural sac, as there are

admitted to be for effusion into the sac of the hip- or the knee-joint, for example." And this writer further adds, "Who, knowing how perfectly recoverable are rheumatic affections of the joints, would propose incision, or even repeated aspirations, except for mechanical reasons?"

It is, therefore, of importance, both as regards prognosis and treatment, that we assign to other agencies than the tubercle-bacillus a position in the etiology of pleurisy. That we should have fallen into the error of giving to tuberculosis a too important standing in this condition has in large part resulted from the uncertainty of the results attending examinations of the pleuritic fluid for the bacillus. From the fact that even in cases of undoubted tubercular origin the presence of the bacillus cannot always be discovered in the effused fluid, we have come to reason, and justly so in the majority of instances, that the tubercle-bacillus acts as a factor in the production of pleurisy, even though its presence cannot be detected in the effusion. That this is invariably the case, however, and that there are not other and important causes of pleurisy, must be denied.

Of these other causes, probably the poison of rheumatism is the most important. Whatever the nature of this poison may be, we know that its effects are chiefly manifested upon the serous membranes, and it is admitted that the structures of the endocardium and of the pericardium are particularly prone to suffer. If these tissues are especially susceptible to the effects of the rheumatic poison, why should not the analogous structure of the pleura be equally exposed? Nor is it a point against this view to cite the frequency with which pleurisy occurs without coincident involvement of the joints, since it is now generally admitted that we may have endocarditis resulting from the effects of rheumatism without at the same time the joints manifesting signs of the affection.

In accordance with this line of thought, Fiedler ("Jahresber. d. Gesellsch. f. Natur u. Heilkunde zu Dresden," 1891), while holding that tuberculosis plays the principal rôle in the causation of pleuritis, calls attention to what he states to be another and not infrequent variety of pleurisy,—viz., the rheumatic form; and he holds to the view that rheumatic pleurisy is etiologically upon the same basis as rheumatic endo- and pericarditis, which so often accompany articular rheumatism; and that, due to the same cause, it can occur spontaneously without involvement of the joints.

So, also, Strümpell, in the eighth edition of

his "Lehrbuch," states that as pleuritis occurs not infrequently as secondary to acute articular rheumatism, so it would appear that in other cases the rheumatic infection tends to become localized in the pleura alone, constituting what might be called a primary "rheumatic pleurisy." This authority further states, however, that it is possible to make this explanation with full certainty in only a few cases, and that most frequently it is justified only when later poly-articular swellings, endocarditis, or other evidences of a rheumatic infection develop. In other cases of apparently primary acute pleurisy, occurring perhaps after exposure, and running a rapid and favorable course, this interpretation of the etiology is to be considered as probable. Not infrequently, however, he continues, the further course of the case clears up the pathogenesis of the disease in an entirely different way.

If, therefore, the statement be correct that rheumatism is an important and not infrequent cause of pleurisy, do we do justice to our patients if we neglect the use of the specific for diseases of rheumatic origin? If the pleurisy be of rheumatic origin, by allowing the poison to remain unopposed in the system for one moment longer than is necessary, we undoubtedly subject our patient to unnecessary risk from that most dangerous of all the complications of rheumatism,—endocarditis.

At the outset, however, we are met with the difficulty of determining which of our cases of pleurisy are rheumatic in origin and which tubercular, and this difficulty will continue until we can with more certainty determine the presence of bacilli or their products in pleuritic fluids. It is possible in these cases, however, to make a therapeutic test as to the nature of the affection, as the administration of the salicylates in cases of rheumatic pleurisy is followed by a rapid decline in the morbid process.

As to the advantage derived from the use of the salicylates in pleurisy, we possess abundant evidence from the highest authorities in the literature upon the subject. Thus, Köster (*Therapeutische Monatshefte*, Berlin, 1892, vi.) reports his experience in a series of thirty-two cases of pleural effusion. In this series aspiration, on account of threatening symptoms or non-absorption, became necessary in but three, and this notwithstanding the fact that they were all cases in which the effusion was of more than ordinary amount. While admitting that the action of the salicylates is not constant, this authority states that the drug should be tried in all cases of primary exudative pleurisy.

He also recommends its use in those cases in which a friction sound is the only evidence of the existence of pleural inflammation, claiming that it quickly lessens pain and results in a speedy decline of the temperature. Nor does he restrict the usefulness of the drug to the primary form of the disease, so called, but, on the contrary, holds that it is of value even in cases of secondary origin. This would attribute to the salicylates a value other than that which they possess as an antidote to the poison of rheumatism. A similar view is also entertained by Tetz (*Therapeutische Monatshefte*, July, 1892), who claims that secondary pleurisy is susceptible of successful treatment by the salicylates.

Jaccoud, in the last edition of his "Medical Pathology" (and *Gazette des Hôpitaux*, 1889, 1890, 1891), emphatically states that in some cases a rapid cure follows the early use of the salicylates, and that the average duration of the disease is lessened. He further claims that he has, often avoided the necessity for the operation for empyema by the use of sodium salicylate. The same authority, quoting Chassagne, says that the latter prefers to either salicylate of sodium or salicylic acid the use of salol, as being better tolerated by the stomach, and at the same time accomplishing with equal facility the resorption of the effused fluid.

Again, Lameray (*L'Union Médicale*, 1891) says that exudations of several weeks' standing will yield to the salicylate treatment, and in this connection the same writer makes the following statement, than which nothing could be more positive or of greater significance: "If this treatment be instituted early, I think Estlander's operation will be, in the future, a surgical rarity."

In the eighth edition of his "Lehrbuch," Strümpell assigns first place to sodium salicylate as a diuretic in the treatment of pleuritis, because, as he says, there has been ascribed to it a specific action in pleurisy; and, further, states that it is of especial value in cases of rheumatic origin, and that many good observers affirm that a primary pleuritic exudate under treatment with sodium salicylate often undergoes rapid resorption and the case otherwise pursues a favorable course. Strümpell also claims that, in addition to its specific action, sodium salicylate also possesses an immediate diuretic effect.

There is, therefore, much difference of opinion expressed as to the manner in which the favorable action of the salicylates is exerted upon pleuritic effusions. That the effusion undergoes resorption partly as the result of the

diuretic action of the drug can admit of no doubt; but in cases of rheumatic pleuritis it would appear not unreasonable to attribute the action of the salicylates to their well-known antidotal properties in relation to the rheumatic poison. That this limits the drug's usefulness, however, many deny; and these claim for it a value in the treatment of cases other than those of rheumatic origin, and even in those cases that are secondary to other conditions. Thus, Dock (*Therapeutic Gazette*, 1893, vol. ix. 78-82) holds the view that the drug's action is specific independently of the rheumatic origin of the disease, and in this connection considers it a significant fact that, in a case of pleuritic effusion placed upon the salicylates, he was enabled to detect the presence of salicylic acid in the effusion.

The dose of the salicylates administered in the treatment of the disease under consideration is usually a large one. Aufrecht (*Berliner Klinische Wochenschrift*, 1886, No. 10) recommends salicylic acid in gramme doses five or six times daily, the patient being kept in the recumbent posture. In two or three days the quantity is reduced to 3 or 4 grammes daily, and so continued for eight or ten days. Köster gives the salicylate of sodium in doses of 1.5 grammes three or four times daily, while others recommend the substitution of salol as being better tolerated by the stomach.

In no article, though only partially embodying the treatment of pleuritic effusion, should mention of the so-called dry method of treatment be omitted. As is well known, the efficacy of this treatment depends upon so depleting the blood-serum that, through its tendency to regain its normal consistency, it will absorb the necessary fluid from the tissues. This depletion is brought about by giving fluids sparingly by the mouth at the same time that we take from the blood its watery constituents by the systematic use of concentrated saline solutions, the latter a method of treating dropsical effusions for which we are indebted to Matthew Hay. By some this treatment is supplemented by the administration of diaphoretics and diuretics. If the blood-serum be depleted, and it possess the power of regaining its normal consistency by absorbing fluid from the tissues, from no source can it obtain such an abundant supply as from the effusion which has taken place into the pleural sac. Thus, under this treatment, very large effusions frequently undergo rapid absorption.

When, in the course of pleural effusions, evidences arise of embarrassment to respiration or to circulation, and, even in the absence of

these symptoms, when the effusion is massive, no matter what may have been the cause of the trouble, we must remove the fluid by mechanical means. When the contents of the pleural sac are serous, this is now usually accomplished by aspiration.

In causing the resorption of pleural effusions by the use of drugs, the question arises whether or not there is a possibility of doing harm to the individual by the absorption and distribution to the tissues of this fluid, which, during its retention in the pleural sac, may have undergone some change that might render it noxious. This is particularly apt to be the case in pleurisy of tuberculous origin, and the possibility of exciting an acute miliary tuberculosis should not be overlooked. Indeed, some authorities hint at the advisability in every instance of pleuritic effusion of withdrawing the fluid by mechanical means, rather than run the risk of such a possibility. Thus, Rosenbach (*Real-Encyclopädie der gesammten Heilkunde*, 1885, iii. 498) says that, in the operation of aspiration, that we withdraw from the use of the economy a certain amount of albuminous material is of no significance, because we do not know what retrogressive changes this material may have undergone, and because there remains the possibility that by the taking up again into the circulation of this substance by quick absorption a latent pulmonary tuberculous deposit may receive renewed stimulation and pursue a rapid course. Undoubtedly, from this point of view, the advisability of the mechanical withdrawal of pleural effusions of tuberculous origin deserves serious consideration.

The treatment of purulent effusion into the pleural cavity is in reality a subject for the consideration of the surgeon, and I will therefore refer to it but briefly.

Cases of empyemata occurring in the adult as a primary condition, in which the effusion takes place rapidly and the consistency of the pus is thin, sometimes result in spontaneous cure after two or more simple aspirations. This is likewise true of the empyemata of childhood, at which period of life effusions are frequently purulent from the onset. Carmichael (*Edinburgh Hospital Reports*, 1893, i. 270-275) reports a large number of pleural effusions occurring in childhood, and arrives at the following conclusions in regard to the removal of the fluid from the pleural sac in this class of patients:

1. That aspiration alone is successful in many cases of limited purulent effusion.
2. That simple drainage with antiseptic pre-

cautions is all that is required in the great majority of cases.

3. That resection of the ribs is rarely needed in children.

4. That irrigation, except in septic cases, is unnecessary, and may be hurtful if not very carefully carried out.

With the possible exception of those cases of purulent effusion occurring under the above conditions, it is but trifling with the life of our patient to trust that a purulent effusion will undergo resorption. Various methods, however, have been devised to be used in connection with partial aspiration to favor the absorption of the remaining fluid, notably that advocated by Senator, who advises that the quantity of pus withdrawn from the pleural sac be replaced by an equal quantity of some antiseptic solution, which, by thinning the consistency of the pus not withdrawn, will hasten its absorption. It is manifestly irrational, however, to suppose that a pyogenic membrane, such as the pleural membrane becomes in empyema, should be capable of taking up through its lymphatics the fluid remaining within the sac, no matter how thin in consistency that fluid may be rendered.

Thus we come to the ultimate conclusion that a purulent pleural effusion is in reality an abscess, and demands the treatment of an abscess in any other locality,—viz., evacuation and free drainage. "Ubi pus, evacua."

In closing, I would draw the following conclusions:

1. That the tubercle-bacillus is the cause of the majority of cases of pleurisy.
2. That a certain number of cases of pleurisy are due to rheumatism.
3. That in the treatment of the rheumatic cases we should employ the salicylates, as having specific action in such cases.
4. That the salicylates are of value in cases of other than rheumatic origin, and their use, therefore, should not be restricted to such cases.
5. That, as a rule, purulent effusions demand evacuation and free drainage.

#### THYROID FEEDING IN PSORIASIS.

By J. ABBOTT CANTRELL, M.D.,

Professor of Diseases of the Skin in the Philadelphia Polyclinic and College for Graduates in Medicine; Dermatologist to the Philadelphia Hospital and to the St. Agnes Hospital, Philadelphia.

SINCE the reports of Bramwell (*British Medical Journal*, 1893, No. 11,933) and Davies (*British Journal of Dermatology*, 1893, vol. v., No. 257) upon the use of thyroid ex-

tract in the treatment of psoriasis, numerous clinicians have from time to time recorded their experiences with this drug, and while the notes have been either positive or negative, it will be found that most of the records have been negative; and while these reports, as a rule, do not state whether the cases have been under treatment or not, I find that the greater number of observers are of the opinion that the drug does not by any means justify its further continuance, especially in psoriasis.

At the recent meeting of the American Dermatological Association, held at Washington in the latter part of May, 1894, Dr. George Thomas Jackson, of New York, reported his experiences with its use in a number of diseases of the skin, and in every instance the drug proved of no value, and, furthermore, it had a deleterious effect in some of the cases.

Recently I find the records of a case being treated by this agent by W. Dale James (*British Journal of Dermatology* for June, 1894), in which he found, after a time, that glycosuria had been produced, and probably with this drug.

If this remedy, which has been supposed to have a beneficial effect in psoriasis or other diseases of the skin of a desquamative nature, be carried to other fields, it might or might not prove beneficial.

I myself have been led, even after seeing so much adverse criticism, to try the drug in cases of psoriasis that appeared in my clinic at the Philadelphia Polyclinic, and I hope that the following cases will prove interesting and instructive to my readers. The experience thus gained in my clinic gives credence somewhat to both sides of this question, and for this reason I take this opportunity to record my results.

**CASE I.—March 29, 1894.**—A young man, twenty-three years of age, being of slight build, five feet five inches in height, and weighing one hundred and twenty-five pounds. He stated that the present eruption began some three years before his visit, and that at the beginning the lesions were mostly confined to the legs and remained in that portion from eighteen months to two years. He had been treated by some obscure means without effect for over one year.

The eruption as witnessed on this date had remained in the same condition for several months. It was confined mostly to the trunk, although other lesions were scattered over the remainder of the body.

Upon the anterior surface of the trunk the lesions were situated on the right side of the chest and upon both sides of the abdomen.

Those on the right side of the chest, being distinctly above the nipple line, were four or five in number, and ranged in size from a nickel five-cent piece to a half-dollar.

Upon the left side of the abdomen I found one lesion, about four inches below the nipple and towards the ensiform cartilage, which was about the size of a silver dollar, also others near the umbilicus, which ranged in size from that of a silver quarter-dollar to a silver dollar.

Two lesions were found upon the right side of this region and directly below the nipple (seven inches below), and were the size of a silver dollar.

Upon the posterior surface of the trunk there were numerous lesions scattered at irregular intervals throughout the region, and ranging in size from a pin's head to that of a silver half-dollar.

Lesions of variable size were seen occupying portions of both the arms and legs.

The lesions were circinate, with the distinctive abrupt edge often witnessed in this affection. I found the peculiar mother-of-pearl and imbricated scale so characteristic of psoriasis.

Itching was present at irregular intervals to an intolerable degree.

At a previous visit he had been ordered 5 drops of the liquor potassii arsenitis, which was to be taken three times a day.

*April 6.*—Was ordered in addition to the above,—

R Thymol, gr. x;  
Ungt. zinci oxidi, ʒi;

which was to be applied thrice daily.

*April 17.*—The disease seems to be but slightly raised upon the surrounding skin; the lesions are, as a rule, small, although closely aggregated. The lower lateral sides of the chest and abdomen appear to be one mass of disease, and encroaching upon the anterior portion of the trunk, runs together and appears as if it was one mass. As there was not any change, I advised the use of cod-liver oil in 2-drachm doses three times a day.

*April 27.*—Eruption no better; was ordered olei copaibæ, 5 drops to be given three times a day.

*May 11.*—Condition about the same. Another change was made on this date, and he was given the desiccated thyroids of Parke, Davis & Co.'s manufacture. I advised beginning with 5-grain doses three times a day.

*May 18.*—Some slight change in the lesions; the scales are not so abundant, and the lesions begin to have the soft, natural, pliable feel of the normal skin.

*May 25.*—Thyroid was increased to 7 grains three times daily.

*June 1.*—Lesions are beginning to fade in color; the edges do not seem so marked; thyroid increased to 10 grains thrice daily.

*June 12.*—Felt perfectly well, although for some reason (unrecorded) the thyroid was decreased to the minimum dose.

*June 28.*—Eruption was almost the natural color of the skin. I advised increasing again to 7 grains thrice daily.

*July 12.*—All the lesions have entirely disappeared (two months after beginning treatment with thyroid).

**CASE II.**—*May 12.*—Male, aged twenty-eight, brass-worker, presented himself at the clinic for the first time, complaining of an eruption on the body. Upon examination, the lesions, which showed the characteristic appearances of psoriasis, were found at different portions of the whole body,—namely, the trunk, arms, and legs, a few being noticed upon the face. He was ordered the desiccated thyroids in doses of 5 grains thrice daily.

*May 19.*—A slight change was noticed.

*May 26.*—The lesions were beginning to show the effect as witnessed in the other case,—that is, the scales are beginning to fall off.

*June 9.*—The lesions very much improved in their outline; the edges are not so prominent; the scales have almost disappeared.

*June 16.*—The old lesions, which were almost devoid of scales, had faded in color considerably, but some new lesions were noticeable on the left forearm and right arm; thyroid increased to 10 grains thrice daily.

The patient did not return after this visit.

**CASE III.**—*June 16.*—Female, aged eighteen, general housework; the lesions, as a rule, were small; in places they formed patches; they were all covered with fine scales. She stated that she had never been treated, though the eruption had at times disappeared spontaneously. She was ordered thyroids in doses of 5 grains thrice daily.

*June 20.*—No change whatsoever; thyroid increased to 10 grains thrice daily.

*June 23.*—The lesions seem to show the change as witnessed in the first case. She did not return after this date.

**CASE IV.**—*May 24.*—Male, aged forty, policeman, five feet nine inches in height, and weighing two hundred and thirty pounds; he had been coming to the clinic, at irregular intervals, for a period of over one year, and during that time had been under several different remedies.

The lesions as witnessed on this date occu-

ried the forehead, especially around the borders of the hair. He had one lesion, the size of the palm of the hand, situated upon the median line of the chest; other and more numerous lesions were scattered over the back, arms, and legs; they were all decidedly itchy. He was ordered the thyroids in doses of 5 grains thrice daily.

*June 2.*—Thyroid increased to 10 grains.

*June 7.*—The man, being very much frightened, came to the clinic in a very nervous condition. He stated that he had pains all over his body, that his hands were tremulous, and that his knees felt as if he had no power to stand erect. He also stated that he had no appetite, and was almost unable to keep awake, either in the day or night, while on duty. Decreased again to 5 grains.

*June 21.*—Deeming that the remedy had been given sufficient trial in this case, I advised a change to some other.

After a careful study of the above cases and the strict discipline followed in the treatment of all, I feel that more benefit can be obtained by the feeding of psoriasis patients with the extract of thyroid than has been generally accredited to it; and while it is possible that some or many of the cases will not respond to its effect, I believe that all those having psoriasis, if they can take the proper dose to affect the disease, will undoubtedly be benefited by it.

Thus, it will be seen that one of my cases (Case I.), a slimly-built, delicately-formed, nervous young man, took and could take a larger dose than a large robust man (Case IV.); and while the dosage used in the first case gave the desired cure, the second case was not at all benefited by it, and, in fact, new lesions formed while he was taking it, and at the same time disagreeable effects were noticed, thus showing that the latter case did not get the proper dose to affect the disease.

We cannot expect that a remedy which has been extolled in this or that affection will give the desired result in all cases using it.

#### STERILIZATION OF CATGUT.

RÉPIN (*Revue de Thérapeutique Médico-Chirurgicale*, June 15, 1894) has found a method of sterilizing catgut by means of heat. He uses the vapor of alcohol heated to 120° C., verifying the sterilization by placing bouillon in the same tubes with the gut; if the bouillon remains clear, the gut is fit for use; but if it becomes turbid, the ligatures should be rejected, as the tubes are infected.

### THE CUMULATIVE ACTION OF DIGITALIS.

A SUBJECT which possesses a great amount of interest to the practitioner of medicine is the question as to whether the most important of the group of cardiac stimulants, digitalis, possesses in any sense what is known as a cumulative action. It is a question which has been discussed *pro* and *con* in the columns of the THERAPEUTIC GAZETTE as long ago as 1888, and in other journals and text-books, until one would have supposed that by this time distinct and definite ideas as to whether this result ever occurs would have been reached. Our attention has been called to this subject once more by the article of Dr. Beaumont Small in "Buck's Reference Handbook of the Medical Sciences" (the supplementary volume), in his article upon "Digitalis." The statements which he makes are the more worthy of notice,

in view of the fact that his contributions to this volume are certainly among the most valuable which the work contains. Not only does he bring to his contributions a wide knowledge of the literature, but he appears to have been very careful to occupy a judicial position in all his utterances in this important volume of medical learning. It is because we are forced to differ with Dr. Small that we write this editorial, being well aware of the large number of statements which he can bring forward, made by competent authorities, that the cumulative action of this drug is never seen. We take our position in this positive manner not only because we believe that such an effect may be produced theoretically, but because we have actually seen it occur in a sufficient number of cases to make us very certain of the correctness of our observation. It goes without saying that much depends upon what we mean by the term "cumulative action." We may indicate that the organ resists the action of a drug or remains free from it for a considerable period of time, and then suddenly gives way to its peculiar influence; or, on the other hand, that a large quantity of the drug is retained in the body, either in the tissues or in the organs which receive it, without entering the active circulation, and that it is only when the tissues become so loaded with the drug that they are practically saturated with it that it is poured into the circulation and immediately exercises an almost toxic influence upon the organs which are susceptible to its power. Again, cumulative action may to a certain extent depend upon frequent dosage of a drug which is very slowly eliminated, and so accumulates in the system. It is worthy of notice in passing that digitalis is probably such a drug, although the important point should not be forgotten that it is so completely destroyed in the organism by oxidation or otherwise that chemists have never been able to satisfactorily obtain either it or any derivative of it from the urine or other secretions of the body. In Dr. Small's article, which we have quoted, he states, "A cumulative action in the sense of an accumulation of the drug in the system followed by an outburst of increased action is no longer feared; no such condition occurs. Toxic symptoms arise only from an overdose or from its prolonged administration, and the condition of poisoning is preceded by its regular train of symptoms." These sentences are difficult of analysis, for he states that toxic symptoms only arise from its prolonged administration. Of course toxic symptoms arise from the prolonged administration of all drugs if the dose is a large one, as chronic poi-

sowing is finally induced. We think that this is one of the points in which a mistake is made. The question is not as to whether digitalis produces toxic symptoms after prolonged administration; it is whether the drug is capable of being administered for twenty-four or forty-eight hours without effect and then able suddenly to develop its full influence. We believe very distinctly that, under certain conditions, this is an action of digitalis, as we have already said. In the first place, aside from the slowness of its elimination, we all know that the drug has an action upon the heart which lasts for a very long period of time. Thus, we have under our care at the present moment a case of rheumatism to which a physician, who had the case before we were called in, was administering full doses of digitalis. It is now a week since this medicine was stopped, yet, notwithstanding this, the effects of the digitalis upon the heart (which are so characteristic) progressively became more and more marked for three days after the administration of the drug was discontinued, and on this—the seventh—day the pulse-rate is only 60, and the heart's action is irregular and still possesses the peculiarities of digitalis. It is impossible to believe that any physician would have administered the drug and ordered its continuance in the face of such symptoms of cardiac distress as the digitalis produced in this instance. In other words, in this, as in many other cases where the patient has been under observation during the entire administration of the drug, perfectly good evidence is obtainable to show that the full effects of the drug were suddenly developed, and that even after it was stopped its effects increased for a considerable period of time. There are two conditions in which, without any doubt, this drug is exceedingly apt to exert this cumulative action. One is seen in cases of ascites, even in those instances where the drug has been given in comparatively moderate dose, as, for example, 5 drops of the tincture three times a day, the other in cases of high fever. In the first of these cases there can be no doubt that removing the fluid from the abdominal cavity is followed by a heightened action of digitalis, when that drug has been administered for a considerable period of time prior to the paracentesis, and indeed this is also true of those cases of general anasarca where the dropsy is relieved by purgation. Those who have given digitalis to any extent in cases of fever must have seen the fact illustrated, which was first pointed out experimentally by Lauder Brunton, that digitalis fails to exert any influence, or at least its ordinary influence, upon the heart if the body tempera-

ture is above 103° F. If they have watched their cases carefully, and have continued the administration of digitalis, they will have noticed when the fever declines, either in the natural course of the disease or because of constant cold spongings, that the digitalis at once exercises its well-known influence, and speedily produces far greater effects than the moderate doses which have been given during the few hours preceding the fall could possibly have produced had their effects been distributed over hours. This is certainly an instance of the cumulative action of digitalis. We believe, on the other hand, that the development of this cumulative influence is not commonly met with in the average case of heart-disease to which the drug is administered, and the symptoms are not to be confused with the characteristic abortive beatings of the heart under the action of excessive doses of this drug; for sometimes the heart is found beating furiously, yet producing almost no radial pulse; at other times it beats with remarkable slowness—45 to 50 per minute—and then quite rapidly, or the beat is intermittent both in strength and in frequency. In still other cases when the doses of the drug have been excessive, either because of their size or cumulative action, a condition of what might be called asystole is produced, in which auscultation of the præcordium can scarcely reveal the first sound of the heart.

So far as we know, all preparations of digitalis are equally liable to produce the condition of which we write. Personally we have always found that the tincture of digitalis fulfilled all the indications, both from a pharmaceutical and therapeutic stand-point, and so prefer it to any other form of the drug.

#### THE TREATMENT OF CANCER.

COLEY, in his collection of cases of malignant growth cured by an attack of erysipelas, and Spronck, in his paper detailing the results of inoculation of the sterilized toxine of erysipelas in nineteen inoperable cases of cancer, have called the attention of the profession to a method of treatment in the line of the therapeutics of the future, and one which, though uncertain in its results and dangerous in its application, holds out a possibility of cure when the operation stage has been passed and the outlook is otherwise absolutely hopeless. The real percentage of cure is, of course, indicated not at all by collections of reported cases, since, until very recent times at least, continued or even more rapid growth of a

neoplasm after a florid erysipelas would have been considered as the natural course of events and hence not deserving of publication. Certainly every surgeon of more than fifteen years' standing will recall not one, but perhaps many, cases of cancer operation in which the growth was apparently quite removed, in which the wound and surrounding parts were attacked by erysipelas or cellulitis, and in which there was recurrence *in loco*. It is difficult to imagine an inoculation made under circumstances better calculated to demonstrate the curative power of erysipelas, and yet such accidental inoculations usually failed. Coley has shown, however, that in a small number of carefully observed, perfectly authentic cases, erysipelas inoculation has succeeded. His statement on this point is not open to doubt, and the only caution to be observed is lest the surgeon who studies collections of cases should be led into the error of hoping too much and, far worse, of promising too much.

Agnew, whose experience in the treatment of malignant growths was enormous, always held that free suppuration following cancer operations lessened the probability of recurrence, though he was one of the first in this country to accept and to teach the principle and practice of clean surgery. Wyeth states definitely that infection by pus microbes will cure sarcoma, and quotes a case in point. From his patient he removed a portion of a large sarcoma, and into the remainder injected arsenous acid. This was followed by violent inflammatory reaction and free suppuration. The patient was cured, and has remained well for ten years. Wyeth attributes the cure not in the least to the caustic action of the arsenic, since only a very small portion of the remaining growth was reached, but rather to the streptococci infection. It seems clear that reported cures of cancers by the various injections, such as pyoktanin, for instance, can be explained on the same ground; though, for the most part, these cases have been so carelessly observed, or at least so imperfectly reported, that they cannot be accepted as instances of veritable cancer cure.

A second case of sarcoma observed by Wyeth was subject to amputation of the leg, and later of the hip; a second recurrence in the hip incision was cured by an accidental attack of erysipelas, and the patient is still living five years later. In a third case an accidental erysipelas resulted fatally; in a fourth an intentional erysipelas was followed by no improvement in a sarcoma of the jaw.

Wyeth agrees with Coley that sarcoma may

be cured by sepsis, particularly by that of erysipelas, though the products of the ordinary pus microbes are also potent. He believes that the sterile products of erysipelas streptococcus are also efficacious. Inoculation into the neoplasm gives best results, though the action is ordinarily through the blood. Adenoid carcinomata react scarcely at all; epitheliomata are sometimes favorably affected.

The discussion on malignant growths, held in the Section on Surgery and Anatomy of the American Medical Association (*Journal of the American Medical Association*, June 30, 1894), was noteworthy from the fact that the modern treatments of cancer—*i.e.*, cauterization, excision, and inoculation—were fully and ably set forth, with their respective claims to recognition and adoption.

As to cauterization, though its mode of application, its action penetrating beyond the tissue immediately destroyed and destroying the cancer cells of lower vitality, while leaving uninjured the normal tissues, and admirable results following its use, were clearly demonstrated, the general consensus of opinion was decidedly against it as a routine treatment, and with this verdict the great majority of surgeons are fully in accord.

Excision, particularly early excision, in the precancerous stage, if possible, was the method of choice, and it was indicated that when the value of this operation shall be more fully recognized, the ultimate mortality of cancer will be far less appalling than at present.

As for inoculation, this shows thus far merely possibilities. The method, however, seems to teach one lesson,—*i.e.*, that suppuration in and about the site of malignant growth exerts a distinct antagonistic effect on the extension of such growth; hence it would seem perfectly logical in such operations to encourage suppuration.

## Reports on Therapeutic Progress.

---

### TRANSFUSION.

VON ZIEMSEN (*Munch. Med. Woch.*, May 1, 1894) uses the following method of transfusion. Under very strict antiseptic precautions, he withdraws, by means of a syringe holding twenty-five cubic centimetres, blood from the median vein of the giver and injects it directly into the corresponding vein of the receiver. Three assistants are required. Three glass syringes with canulæ and a large vessel containing sterilized salt solution and standing

in a water-bath are also needed. The salt solution serves the purpose of washing out the syringe before it is used anew. In this way 200 to 300 cubic centimetres of blood may be injected without fever or local reaction. Unpleasant results never occurred. The destruction of the red cells cannot be considerable, as hæmoglobinuria was never present, nor yet free hæmoglobin in the blood. According to the author's experience, the good effects of injecting blood in acute anæmia is beyond doubt. In severe progressive anæmia it is more questionable. He reports such a case in a woman, aged thirty-eight, to whom seven injections, amounting in all to 900 cubic centimetres of blood, were given with considerable benefit. Subcutaneous infusion is inferior to transfusion, but is recommended if proper assistance cannot be obtained. There may, however, be pain at the site of the infusion, and a moderate degree of fever may also occur.—*British Medical Journal*, June 16, 1894.

### THREE CASES OF ANEURISM TREATED BY VENESECTION.

DAVISON writes upon this subject in a useful paper, which he concludes as follows:

Bleeding in the treatment of aneurism is no innovation. It was, even according to Dr. Balfour, suggested by Hippocrates, and it formed the basis of the celebrated treatment of Valsalva,—a treatment which fell into discredit owing to the abuse of bleeding which it advised, and because, at the same time that it tended to consolidate the aneurism, it also tended to prevent this consolidation. Medical literature presents cases where spontaneous rupture of aneurisms has been followed by contraction of the sac, relief of symptoms of compression, healing of ruptured wound, and apparent prolongation of life. If such benefit can follow the spontaneous rupture of an aneurism, may not the same benefit be obtained by the harmless extraction of blood from a vein? The abuse of a remedy is not a sufficient cause for excluding its legitimate use, nor must the intelligent physician be bound by the fashion of the day, which at one time decrees abuse of bleeding and at another time its total rejection.

The dilatation of an aneurism is produced by the pressure of the blood stretching its coats, weakened by disease. If these coats retain contractile elements, it is evident that a diminution of the volume of blood within the aneurism, together with a diminution of the pressure of the blood, if carried to a sufficient

extent, will enable the aneurism to contract; but the lowering of blood-pressure after hemorrhage is only temporary, and after a short time this pressure regains its former force. Does it, then, follow that conjointly with the return of the force of the blood-pressure the aneurism will again dilate to its former extent, and thus bleeding come to be of no value? Certainly not, for in order that the aneurism may return to its former degree of dilatation it is necessary either that in a few days changes shall take place within its walls, lessening their power of resistance, or that the blood-pressure shall attain to a degree which it had not reached before; for if, before, a certain amount of blood-pressure was necessary to keep the aneurism in its over-distended state, now that it has contracted, to keep it again stretched as before would require the same amount of blood-pressure that maintained it distended, plus another quantity necessary to overcome the contractility of the walls now contracted, and therefore in more favorable conditions to overcome resistance. It follows, therefore, that when the walls of an aneurism retain a sufficient quantity of contractile elements, the contraction which will take place on lessening the volume and the pressure of the blood after a good bleeding may, with judicious care, be maintained even after the blood-pressure has regained its former strength. In the treatment of aneurisms three principles must be kept in view,—the contraction of the aneurism, the hypertrophy of its walls, and, lastly, the deposition of fibrin within its cavity. The first indication can be carried out by a copious depletion, together with absolute rest for several months and the ingestion of but a limited amount of liquids. The second indication can be carried out by the internal administration of iodide of potassium, as recommended by Dr. Balfour, avoiding excessive doses, which may accelerate the pulse. The third indication requires, in addition to the above measures, a diet which, without being very rich to stimulate unduly the circulation, will at the same time be nutritive enough to produce a sufficient quantity of fibrin. The principle advocated in the treatment of aneurisms is not the impoverishment of the blood, but the temporary diminution of its volume and of its pressure, so as to enable the aneurism to contract and place it thus under circumstances more favorable for the operation of other remedial agents which tend towards its consolidation. Repeated bleedings at short intervals have been known to be positively harmful; but keeping in mind the above principle, the intelligence

of the physician will indicate when and how to bleed. Judicious bleeding in the treatment of aneurisms will prove to be a valuable element, by means of which alarming symptoms of compression may be quickly removed, instant death sometimes averted, and the patient placed under favorable conditions for the prolongation of his life.—*Lancet*, May 19, 1894.

#### *TETANUS TREATED WITH ANTITOXIC SERUM.*

GIUSTI and BONAIUTI (*Gazz. degli Ospitali*, May 12, 1894) describe a case of tetanus treated with antitoxic serum. The case is remarkable on account of its clinical course, its successful issue, and the amount and power of antitoxin used. The patient, a robust man, received severe lacerated wounds on the face—one of these being deep and dividing the zygomatic process—in a railway accident. All the wounds were freely contaminated by earth, and the patient's leg was also the seat of a simple fracture. Notwithstanding prompt and careful cleansing with antiseptics, etc., some trismus and exalted sensibility made their appearance on the day after the occurrence, leading the observer to suspect the onset of tetanus. Nevertheless, the trouble disappeared, and the patient did well until January 7,—twenty-one days after the accident. Undoubted tetanus then made its appearance, characterized by great respiratory and cardiac difficulties and obstinate vomiting, in addition to the more usual symptoms of a severe case. After three days of unavailing application of the ordinary treatment,—chloral, calomel, vapor-baths, etc.,—a consultation was held with Tizzoni, who at once instituted the treatment with antitoxic serum from a highly-immunized horse (antitoxic equivalent 1 to 10,000,000). On February 1 two injections of this serum (40 and 20 cubic centimetres) were given. After these the patient experienced a period of calm and got a little sleep. Next day, the temperature being high and tetanic symptoms still prominent, two injections (20 and 10 cubic centimetres) of serum from an immunized dog were given (relative power 1 to 10,000,000). The tetanic symptoms then disappeared for a time, to reappear, however, in a very mild form during the night. On February 3 an injection of dog's serum (10 cubic centimetres) was given in the morning, and in the evening 50 centigrammes of alcohol precipitate of the horse serum, dissolved in water. On February 4 to 8 further injections of dried precipitate or of dog's serum were made, although the non-appearance of further

tetanic symptoms probably rendered some of these superfluous. From this time the patient's condition improved steadily. He was at last discharged cured. The total amounts of protective material used were: horse serum, 60 cubic centimetres; dog serum, 110 cubic centimetres; dried alcoholic precipitate of immunized horse serum, 2 grammes, equivalent to about 20 cubic centimetres of serum. Attention is drawn, first, to the early symptoms, appearing on the day after the accident, and due probably to absorption of a dose of ready-formed toxin from the contaminating earth; secondly, to the occurrence of a severe attack of "cephalic" tetanus after the long incubation period of twenty days; thirdly, to the complete failure of ordinary measures and the rapid success of the specific treatment; lastly, it was suggested that the dog's serum had probably a more potent effect than the other variety in reducing temperature. The dried precipitate of serum was somewhat difficult to use, on account of its imperfect solubility and the risk of contamination during the process of dissolving it.—*British Medical Journal*, June 16, 1894.

#### *THE ACTION OF ASPARAGUS ON THE KIDNEY.*

Three years ago WILKS sent a short communication to the *Lancet*, requesting the opinion of the profession on this subject. He therein stated that, in spite of books declaring asparagus to be a diuretic, he had observed that the very contrary was its action. Four letters came in reply, written by medical men. Three of them stated that from direct observation they had ascertained the inhibitory action of asparagus on the function of the kidneys, so that frequently only a third of the normal quantity of urine was secreted after eating this vegetable. The fourth gentleman said he had no knowledge of his own, but believed asparagus to be a diuretic, as he had always understood it to be so. The question of this vegetable's action in the economy is of little importance when it is so universally eaten and approved of, but it is one of interest in connection with the history of medicine as a science and art. In other sciences knowledge has grown from small beginnings, so that they have a solid foundation and superstructure; but the practice of medicine has existed from the remotest ages and was born of superstition. Consequently, a large part of our advance has been by getting rid of and overthrowing error. The writer has on his shelves a "Herbal," published about a hundred years ago, describing the

value of a vast number of plants which are now discarded as useless; but that a positive error, and one the very reverse of the truth, as regards the action of a well-known vegetable should still be propagated in books is a most remarkable fact and, as regards the whole subject of therapeutics, a very sad one.—*Lancet*, April 28, 1894.

#### PIPERAZIN.

*Apropos* of Dr. Stewart's interesting paper recently published in the THERAPEUTIC GAZETTE, the following summary of a paper by GORDON SHARP is of value:

1. Piperazin is not wholly oxidized in the body, and may be detected in the urine of those to whom it is exhibited.

2. Piperazin in solutions of one per cent. in normal urine, when kept in contact at a temperature of 39° C. (body temperature) for a given time, has the property of dissolving to a great extent a fragment of a uric-acid calculus.

3. That the stronger the solution of piperazin in urine (up to 7.5—) the earlier did the solvent action begin and the more rapid was the completion.

4. That, notwithstanding this, with the stronger solutions of piperazin in urine the rate of solubility was not so markedly rapid over the weaker solutions as might be expected.

5. That the solvent action of piperazin in similar circumstances was greater than any other of the substances that were employed,—namely, borax, lithium citrate, sodium carbonate, and potassium citrate.

6. That piperazin, in weak and strong solutions in urine, converted the undissolved portion of the calculus into a soft granular or pulpy condition.

7. That neither borax, lithium citrate, sodium carbonate, nor potassium citrate in similar circumstances rendered the fragment of calculus soft or pulpy.—*British Medical Journal*, June 16, 1894.

#### TREATMENT OF SEA-SICKNESS BY CHLOROBROM.

In the THERAPEUTIC GAZETTE for September 15, 1892, p. 617, we published an abstract of an article on the use of chlorobrom in seasickness by CHARTERIS, who now makes a further report:

1. In long sea-voyages no prophylactic benefit can be secured by the use of chlorobrom unless for two nights before embarkation the pas-

senger pays due attention to the stomach and bowels by taking a cholagogue pill. Further, in the case of a person who dreads a voyage, a dose of the solution should be taken.

2. The diet on board ship should be "spare and dry." Soups, pastry, and sweets should be especially avoided, and no full meal should be indulged in. A hypnotic dose ( $1\frac{1}{2}$  tablespoonfuls for a male and 1 tablespoonful for a female) should be taken for three nights.

3. In short voyages, when the steamer leaves, perhaps, at 10 P.M., the passenger should immediately retire to rest and take one of the doses mentioned.

4. In a shorter passage across the Channel a teaspoonful should be taken before going on board.

5. By following these directions immunity from sea-sickness is obtained in the great majority of cases, but if they be not followed it is to be remembered that chlorobrom has no effect in arresting an outburst of vomiting. If it is given in a teaspoonful dose every ten minutes until a tablespoonful and a half or a tablespoonful have been taken, it will almost invariably check retching and depression.—*Lancet*, April 21, 1894.

#### INFECTION BY THE TRICHINA SPIRALIS.

ASKANAZY (*Centralbl. f. Bakt.*, Bd. xv., No. 7) observes that two questions await solution in regard to the process of infection by the *Trichina spiralis*: (1) how do the embryos which, according to the general view, are deposited only in the lumen of the bowel, pass through its wall? (2) how do they reach the striated muscles? In the belief that an examination of the bowel-wall in cases of trichinosis would assist in the decision of both questions, Askanazy infected rabbits with the parasite; in seven to ten days the intestines were removed and placed for fixation in Flemming's fluid. Pieces were embedded in celloidin, cut, and stained with safranin. The following facts were established:

1. The female parasite penetrates into the villi and mucous membrane generally, not deeper, however, than the muscularis mucosæ, and lies in that membrane or in a chyle vessel.

2. None of the specimens showed embryos lying free in the tissues of the intestinal wall or in its blood-vessels.

3. Embryos were found in the lumen of the chyle vessel of a villus.

In one case a parasite filled with embryos projected into the chyle vessel, which also con-

tained them, thus rendering it very probable that they had been deposited in the vessel. The investigation would appear to show that the young trichinæ are deposited in the lymphatics and are carried away by the lymph-stream. The discovery of embryos in the mesenteric glands (Virchow, Gerlach) is in accord with this opinion. The following considerations are against the old view that the embryos are deposited in the lumen of the bowel and subsequently bore their way through its wall:

1. The uncertainty with which the embryos are found in the bowel lumen, as shown by a review of the literature on trichinosis.

2. The author's examination of a great number of fresh specimens of intestinal mucus failed to show a single free embryo, even when the female trichinæ were filled with young.

3. Embryos were found only twice in the bowel lumen in a large number of sections, while the adult parasites were plentiful there.

4. As the parasite deposits a large number of eggs, embryos should be numerous in the bowel contents if the deposit took place in the lumen. Against the boring theory is the fact that nobody has yet seen an embryo lying free in the bowel wall. The rare occurrence of young parasites in the lymphatics in these sections is explained by the author on the theory that they had been rapidly carried away by the lymph-stream.—*British Medical Journal*, June 16, 1894.

#### BICHROMATE OF POTASSIUM AS A REMEDY IN GASTRIC AFFECTIONS.

Notwithstanding the assertion made in 1883, and supported by much illustrative evidence by so high an authority as Vulpian, of the value of bichromate of potassium in the treatment of several forms of gastric affection, this substance has not yet gained a position among the many substances that are used in the treatment of these affections, and but meagre reference is made to it in only a few works on medicine and materia medica. Previously to Vulpian's recommendation it had been used by internal administration as an emetic, and with varying success in syphilitic, broncho-pulmonary, and nervous disorders; and Drysdale had advocated its employment in affections of nearly all the important organs of the body. Having in 1884 treated with gratifying success a case of persistent gastric disorders by the administration of small doses of bichromate of potassium, he has since that time administered it in a large number of cases. The results have been so favorable that he feels justified in stating his

opinion of the therapeutic value of this substance and in briefly recording a number of the cases of gastric disorder in which it was used by him. With a few exceptions, the cases have been those of hospital patients. While such patients give the best opportunity for determining the effect of medicinal substances, it is not to be overlooked that, in some respects, they are also placed in more favorable conditions for successful treatment than the majority of private patients. In order to simplify the therapeutic problem, the medicinal treatment was as far as possible limited to the administration of bichromate of potassium. This limitation, however, could not be adhered to in all cases; but only those cases will be described in which the drug alone was administered, or with the addition of other remedies, such as purgatives, rendered necessary by the circumstances of the patient, and unlikely to obscure the effects of the chief remedy. He records the cases in two groups, the first comprehending eighteen cases of various forms of dyspepsia unassociated with evidence of gastric ulcer, the second ten cases in which distinctive symptoms of ulcer had been present at some previous time.—*Lancet*, April 14, 1894.

#### TREATMENT OF PERIPHERAL NEURITIS.

LEYDEN (*Berl. Klin. Woch.*, No. 20, 1894) discusses the treatment of multiple neuritis. He considers that in the case of neuritis following acute specific diseases, care during convalescence, as to nourishment, rest in bed, and avoidance of over-exertion, contributes to prevent its occurrence. "Etiological treatment" (removal of the cause) and treatment of the primary malady as in diabetes are of the first importance. There is no specific remedy for multiple neuritis, and treatment by drugs does not play a very important part. Owing to the fact that rheumatism is not infrequently an element in the etiology, salicylate of sodium and other antirheumatic drugs had been used without producing any good results in the majority of cases. Antipyrin, phenacetin, exalgin, euphorbia, and methylene-blue were sometimes of use for the relief of pain, but it was often necessary to resort to morphine, chloral, sulphonal, etc. Strychnine, formerly much used, but lately fallen into the background, deserved to be tried; by increasing the excitability of the affected muscles, it favored the return to normal function and nutrition; it ought especially to be resorted to in progressive cases in which the respiratory movements were threatened. Leyden prefers to use it as a subcutane-

ous injection ( $\frac{1}{8}$  grain to  $\frac{1}{4}$  grain twice daily). Massage and baths were valuable auxiliaries, which were indicated, especially the latter, in the later stages of the disease. General hygienic treatment was of much importance. Rest—as a rule, rest in bed—was of the first importance in the early stage; in the later stage, feeding. Finally, in the latest stages of all, moral suasion, rousing the patient's latent energies, was often of great value. Passive movements, and encouraging the patient to make active movements, were generally attended with better results than massage in this stage. Electricity, formerly used too much, was now used too little, but its usefulness was greatly limited by the fact that in many cases the pain caused was too great to permit the treatment to be continued.

*A LARGE QUANTITY OF MORPHINE  
TAKEN HYPODERMICALLY WITH  
SUICIDAL INTENT; RECOVERY.*

The following case of attempted suicide is recorded, not from any novelty in the way of treatment, but on account of the enormous dose (estimated at 12 grains) that was taken and from which recovery ultimately resulted. The writer was sent for one evening about 11 P.M. to see a servant-girl who had "poisoned herself with opium." On seeing her a very few minutes after she had taken the opium, the reporter found her already stuporous, drowsy, and with her pupils much contracted. She had taken some morphine hypodermically, the bottle and syringe being by the bedside. Subsequently, inquiry elicited the facts that she had been accustomed to go to the druggist with her master's prescription, who was taking morphine hypodermically under medical advice, and that her knowledge of his taking it in this manner suggested a ready means of self-destruction. The druggist, believing that she had come for the drug on her master's order, had no hesitation in supplying her. She obtained the hypodermic syringe by the same means. On examining the girl's arm, seven recent acupunctures were readily discernible, and she subsequently stated that she had taken six syringefuls of the solution. The syringe was a 20-minim one, and at least three drachms of the solution were missing from the bottle. There was no sign on the night-dress or bed-clothes of any of the solution having been spilt, and only one of the acupunctures was bleeding; it is probable, therefore, that two drachms of morphine were taken. Unfortunately, this can, of course, be only a matter of

surmise. The usual means were employed to keep the patient alive,—viz., atropine (four grains in  $\frac{1}{8}$ -grain doses were given during twelve hours at short intervals, without any result on the pupils), galvanism, wet towels, cold coffee, exercise, artificial respiration, etc. The respiratory centre was affected in far greater degree than the cardiac. Twice during the twelve hours following the administration of the morphine artificial respiration was called for, once for twenty minutes and again for five. Lividity and blueness of the face were constant and pronounced. The iris was contracted to such an extent that the pupil appeared to be quite absent, not even the space of a pin's point being discernible in the muscle, and the eye appeared as covered entirely by the iris. The conjunctival reflex was absent for some hours, and the eye appeared glassy and dull. After twelve hours' treatment symptoms of improvement showed themselves, but for no less than thirty-six hours after taking the poison had the treatment to be persevered in at intervals. If the patient was allowed to sleep, even after twenty-four hours, the respiration ceased after two or three minutes, and lividity and blueness of the face rapidly supervened. She required constant rousing, and even exercise from time to time. The girl was nineteen, and had never to her knowledge taken morphine previously in any form. The solution was of British Pharmacopœia strength.—*Lancet*, March 17, 1894.

*FERRATIN.*

Ferratin is prepared by exposing a mixture of certain proportions of white of egg and an iron salt to the action of slight heat in an alkaline medium. It is a red-brown powder, little soluble in distilled water, but soluble in presence of soda. MARFORI (*Ann. di Chimica e di Farmacologia*, February 1, 1894) has investigated this substance, and his conclusions are as follows: It contains from seven to eight per cent. of iron. It is absorbed in notable quantities from the intestines, and when injected directly into the blood-stream it does not appear to be excreted either by the kidneys or the intestines, save in minute quantities. This is a great contrast to what happens with the inorganic salts of iron, which are mainly excreted into the intestines. It is a remarkable fact that the liver of many animals examined is found to contain naturally a substance closely resembling the artificial ferratin, and in considerable abundance. It appears to be also identical with the "hæmatogen" isolated by Bunge from the egg. Bunge proved that this substance serves as material for

the formation of hæmoglobin, so that ferratin should be a really valuable blood food. Clinical experience has proved it to act in this way, and without causing any constitutional disturbance. It may be given in doses of 15 to 30 grains daily, care being taken not to associate it too closely with acid materials.—*British Medical Journal*, June 16, 1894.

#### THE ANTITOXIC FUNCTION OF THE LIVER.

Padua, through Professor Lussana, Brussels, through Professor Heger, and Geneva, through Professor Schiff, have of late years been associated with special investigations into the physiology and pathology of the liver, and now Rome has fallen into line with these sister schools by a series of interesting researches into the same viscus. It has been already established by the above-named biologists that the liver possesses a power of retaining certain poisonous alkaloids in high proportion and in their most active state,—that is, when injected into the circulation and not merely absorbed by the mouth. Explanations have been hazarded as to this protective power of the liver against these toxic agents, and quite recently Dr. Schupfer, working under Professor Colasanti, Lecturer on Physiological and Clinical Chemistry in the University of Rome, has contributed elaborately to the solution of the question. His experiments were made on frogs,—animals which tolerate removal of the liver well, and keep alive for days after the operation, nay, in some cases, for weeks. The alkaloids were injected into frogs in their normal condition and into those which had been operated on, and every care was practised to watch the phenomena resulting. The alkaloids used were cocaine, atropine, apomorphine, and pilocarpine. Dr. Schupfer embodies his conclusions in a memoir read before the Accademia Medica di Roma, and they are to the following effect: the liver, by its sole intrinsic action due to the specific activity of its cellules, can diminish the toxic power of the alkaloids with which it is brought into contact. Such action is manifested not only in the case of poisons introduced through various channels into the organism, but also in the case of poisons elaborated internally within the organism itself in consequence of putrefactions or of products due to the activity of the tissues. From this he deduces a practical lesson,—that, namely, of having recourse to internal disinfections and to a special alimentation, so as to obviate or to minimize “autotoxication” in all those

maladies in which the liver does not perform its functions normally.—*Lancet*, March 17, 1894.

#### TREATMENT OF APOPLEXY.

PRESTON, of Baltimore, believes that in the treatment of apoplexy more might be done in the prodromal stage if this condition were more carefully studied and oftener recognized. There are no constant or certain prodromata, but in a considerable proportion of the cases here related the history obtained afterwards from the patients showed the existence of headache, vertigo, or a sense of fulness in the head, numbness of one side, etc. These symptoms in some instances existed for a week before the apoplectic attack. It is very important to heed these warnings, especially in cases where there is atheroma of the vessels, or where there is high arterial tension without atheroma. Rest, vascular sedatives, nitroglycerin, large enemata, will often modify the force of the circulation and thus tend to avert the rupture of the artery. Some years ago the writer called to see an elderly woman, stout, with flushed face, headache, and unusually high arterial tension. While waiting for the family physician, she was kept absolutely quiet, with ice to her head. While consulting in the next room, the patient, against orders, got up to use the commode; the arteries could stand no further strain, rupture occurred, and she died in half an hour, with all the symptoms of intracranial hemorrhage. Venesection would probably have averted this disaster. It rarely happens that the physician sees clearly enough to make use of bloodletting. After the rupture of the artery has taken place, it is doubtful whether venesection does any good. The most important part of the treatment of apoplexy is rest. There is no way by which the bleeding can be stopped, and it is probable that in the great majority of cases the increased intracranial pressure tends to control the hemorrhage. The ruptured artery or miliary aneurism is small, as a rule, and it is generally soon occluded by clot. If the amount of hemorrhage is moderate and not in a vital part of the brain, recovery, more or less complete, will take place if the clot remain in its first position.

Very often it happens that the original location of the clot was not specially dangerous, but from gravity, or as the result of exertion, the clot has forced its way through the soft brain-tissue and done irreparable injury to more important structures. This can often be seen post mortem and the track of the clot made out. From this it follows that the great-

est care should be exercised to prevent any more moving of the patient than is absolutely necessary. If it be possible, the patient should be laid down on a sofa or mattress in the room where the attack occurs and no attempt at movement made for twelve or twenty-four hours. It is better to slightly elevate the head by pillows, since this probably tends to modify the force of the heart's action in the cerebral vessels, and at the same time allows respiration to be carried on rather better than when the patient is perfectly flat. Opening the skull has been resorted to, but it is doubtful whether this is advisable, except in the case of meningeal or cortical hemorrhage. The ice-cap to the head is of some use in allaying restlessness, and is extremely good treatment for the relatives and friends. In regard to drugs in this early stage there are practically no therapeutic indications that can be successfully met. The use of ergot and that class of remedies is of more than doubtful propriety. Aconite may sometimes be used to advantage in controlling a too forcible heart's action. As soon as the patient can swallow, it is the author's custom to administer a mixture of bromide and iodide of potassium, 30 to 40 grains of the former and 10 grains of the latter, and this is kept up for several days, then the bromide is omitted and the iodide used alone in increasing doses. In regard to the custom of administering croton oil or some drastic purge during the early stage, although sanctioned by almost immemorial usage, it is not only useless, but exposes the patient to the risk of making dangerous exertions, besides putting him in a filthy condition. The same objections in part apply to blistering and to the use of mustard. It is important to attend to the bladder and draw off the urine at regular intervals. The throat should be kept as free from mucus as possible and the surroundings of the patient rendered comfortable. These points have perhaps been dwelt upon with unnecessary minuteness, but one so often sees these cases handled in a mischievous manner. The physician, realizing the futility of any active treatment, is too apt to yield to any suggestion made by the family, and the object of this paper is to insist upon a simple and rational treatment of this condition.—*Maryland Medical Journal*, June 23, 1894.

#### NOTE ON THE ACTION OF IODINE.

The value of iodine as an absorbent has long been known. It is used to cause absorption of enlarged glands, thickenings due to chronic inflammation, and serous effusions, and this action

is believed to be due to a stimulation of the lymphatic system. Perhaps the most remarkable results due to the action of a compound of iodine as an absorbent are those which were attained by Major Holmes and Captain Cunningham in the treatment of goitre in India. They recommended that the enlarged thyroid should be smeared over with the red iodide of mercury ointment, and that then the patient should be made to sit with the neck exposed to the rays of the sun or of a hot fire for many hours. The results were extraordinary. Sixty thousand natives were treated gratuitously in two years, and a cure was almost always effected. Turner's object in presenting this communication is to offer a suggestion from the point of view of the physicist as to the mode of action of the iodine in these cases. We use iodine in physical experiments to cut off the visible rays of the spectrum. A solution of iodine in bisulphide of carbon will quench the visible rays of the sun, but will transmit the invisible heat rays. The solution is, in fact, remarkably transparent to the heat rays; it is diathermatous. Professor Tyndall, in 1868, was the first to point this out. The fact that the action of the red iodide of mercury is much intensified by exposing the patient to the direct rays of the sun has appeared to the writer to depend upon the physical action of the iodine. Further, the fact that the red iodide is the most efficacious points in the same direction, because the red substance would also serve to transmit the heat rays only. The solar radiation would be filtered by the application, and the gland would be subjected to the full blaze of the calorific rays without the vibrations of its molecules being altered by the visible rays. Professor Tyndall made some experiments with paper reddened by the red iodide, and found that it was also highly transparent to obscure radiation; it therefore falls into line with simple iodine. If the suggestion above made is correct, it is improper to cover the diseased parts to which iodine has been applied; we ought rather to expose them freely to the rays of the sun, or, failing that, to those of a good fire.—DAWSON TURNER, *Lancet*, May 12, 1894.

#### NOTE UPON PROFESSOR ANSCHUTZ'S PURIFIED CHLOROFORM.

PILCHER, the well-known surgeon of Brooklyn, contributes an article on this substance to the *New York Medical Journal* of June 23, 1894.

Professor O. Weitzel, of Bonn, has recently brought forward new chloroform, for which the claim is made by Professor Anschutz, its origi-

nator, that by the employment of salicylic anhydride ( $C_7H_4O_3$ ), obtained by the action of phosphorus oxychloride on salicylic acid, forming what is known as salicylide, for purposes of purification, an absolutely pure chloroform results. By the action of the salicylide upon the chloroform a salicylized body is obtained, in which the chloroform serves the same part as the water of crystallization in many salts, and consequently when heated the chloroform is separated in a pure state.

The first point to be noted in connection with its use is the fact that, owing to the absence of that pungent odor so commonly present in ordinary chloroform, there is a marked absence of hesitancy in the respiration and the occasional refusal to breathe observable in many cases where the latter is employed. The new preparation possesses a rather pleasant aromatic odor.

Whatever the cause, it is a well-known fact that in many persons, particularly those who have been in the habit of imbibing rather freely of alcoholic stimulants, even with the most careful administration of ordinary chloroform, there is a well-marked stage of excitement, this frequently amounting to violent struggling. Even in this class of cases this stage of the administration is only marked by an occasional exclamation when the salicylide chloroform is used.

The narcotic effect of the agent is obtained somewhat less rapidly than with common chloroform, and the patient must be carefully watched during the progress of the operation, to see that he does not come out from under its influence. Slow narcotism and quick recovery are not considered disadvantages by skilled anæsthetizers, for the reason that so profound an effect is not obtained, the purposes of the anæsthetization are completely fulfilled, and the element of danger is largely eliminated. Complete anæsthesia can be brought about in ten minutes; a longer time is very exceptionally required.

Every surgeon of experience dreads the cases in which chloroform produces a very rapid and at the same time a profound narcotic effect. In fact, statistics of fatal chloroformization show that in the large majority of cases the dangerous symptoms supervened very shortly after the commencement of the administration. It is likewise true that the cases in which violent struggling takes place are also to be dreaded, and many surgeons refuse to permit of the continuance of the chloroform, substituting ether therefor even when this has been apparently contraindicated, preferring to

accept the chances of the supposed untoward effect of this agent upon atheromatous vessels, weakened respiratory organs, or diseased kidneys, rather than risk the occurrence of a catastrophe upon the operating-table.

Next, the condition of the pulse is of importance in connection with the employment of the new chloroform. The heart's action, in no case under the writer's observation, has been either accelerated or weakened by its use. On the contrary, when the pulse had been weak and excited prior to the administration, as frequently observed in nervous women, as soon as the effect of the salicylide chloroform has been obtained a most pronounced improvement has been observed in this respect. A pallid face under these circumstances becomes of the pinkish hue of health, and remains so until long after the effects of the chloroform wear off; provided, of course, that excessive loss of blood, the prolonged manipulation of the abdominal contents, or other untoward circumstances incident to the operative procedure do not occur to produce the opposite effect.

Next, it is to be noted that patients recover consciousness much more promptly following the administration of Anschutz's chloroform than with the article heretofore in use. This occurs without those much-dreaded after-effects which are so marked a feature following anæsthetization with either chloroform or ether, as usually employed. In the case of an old man of seventy-four, upon whom the author operated for cerebellar abscess following middle-ear disease, in the practice of Dr. Zabriskie, of Glen Cove, the patient arose from the operating-table and walked across an intervening parlor to his bedroom, without apparent effort, within fifteen minutes after the withdrawal of the anæsthetic. This is not an exceptional experience, for it has been repeatedly noted that a marked absence of the usual head-symptoms, restlessness, muscular weakness, nausea, vomiting, and anorexia is a pronounced feature of the use of this agent.

A word as to the method of administration. At the present day no surgeon of experience will permit his anæsthetizer to administer chloroform by any other than the drop method. The days of forcing the administration by pouring the chloroform in a stream upon the mask or folded napkin have gone by. Steadily supplying the chloroform drop by drop, keeping up by this means the administration of a small dose frequently repeated, produces the desired effect in a length of time sufficient for all practical purposes, and relieves the oper-

ating surgeon's mind of much anxiety in this respect. While chloroform purified by Professor Anschutz's process can be given with somewhat greater freedom without the risks incident to rapid administration of common chloroform, yet the author himself pursues the drop-by-drop method with the head lowered, precisely as he would in ordinary chloroformization.

The quantity of the new chloroform required, even in the hands of those not skilled in its use, averages about one cubic centimetre for each three minutes of complete narcosis. In case the anæsthetizer is accustomed to its use, and keeps the patient just evenly balanced between unnecessarily deep narcosis and the beginning of the return of consciousness, a smaller quantity will suffice.

It is furnished by the manufacturers in brown-colored, graduated bottles, containing fifty grammes each, a quantity sufficient for the purpose of an average operation. An exceedingly simple dropper device is furnished with each bottle.

#### INTRALARYNGEAL THERAPEUTICS.

GORDON SHARP, in writing on this subject, says that, like everything else under the sun, the idea of the treatment of diseases of the respiratory tract by the direct application of drugs to the interior of the larynx is not a new one, but it is only within eight or ten years that it has been practically employed, and that in Edinburgh and Vienna chiefly. At first intralaryngeal injection was chiefly made use of in the treatment of phthisis, either with the view of applying antiseptics directly to the lungs, or of killing the bacillus, or of alleviating the troublesome cough. If with the former intention, it is certainly highly utopian.

The latest contribution to the literature of the subject from the pen of Professor Grainger Stewart shows the value of this plan of treatment in bronchiectasis, and it is probable that this is the disease which is likely to be most influenced by intratracheal treatment. By the old-fashioned methods of giving creosote or guaiacol by the mouth or by inhalation, patients are made ill before one is able to do them much good, for it cannot be doubted that some of the attacks of sickness and vomiting which occur in the course of the treatment of bronchiectasis by the persistent use of creosote are due to poisoning, and at the best one may only be setting a thief to catch a thief, for some of the ptomaines due to decomposition of the secretions in the dilated bronchial tubes must have

entered the circulation. By applying creosote, guaiacol, or other antiseptic directly to the interior of the trachea, whence it is certain to trickle down into the bronchial tubes, one may be able to prevent to a great extent the formation of putrefactive bodies, and it is the author's belief, founded upon experience, that this may be accomplished, and that by passing down antiseptics the patient can be prevented from giving himself mild attacks of septicæmia, which not only wear out his strength, but may even cut him off, and he is being placed on the high road towards recovery. The most probable cause of bronchiectasis is an atrophy of the walls of the bronchial tubes. The resulting dilatation is not a final one, but goes on increasing unless checked, and nothing so much tends to aggravate the condition as the filling up of the cavities and decomposition of the contents, with the production of foul gases. Now, if the secretion can be lessened and at the same time kept comparatively sweet, the tissues are given a chance of regaining a certain amount of tone, while at the same time those septicæmic attacks already referred to are prevented, while also the comfort of the patient is increased by diminishing the disagreeable odor and by relieving the irritating cough so frequent in bronchiectasis. Drugs injected into the trachea, while exerting a local action in the lung and bronchial tubes, find their way into the circulation, as proved in a case. A solution of menthol and guaiacol in olive oil so administered was detected in the urine in two hours, or rather the menthol was found, but the guaiacol could not be discovered, although tested for on several occasions. This points to guaiacol being broken up in the kidneys into some body which does not give the reaction. One can hardly hope to obtain brilliant results by the intralaryngeal method in cases of phthisis. Antiseptics so used have little effect upon the course of the disease in general; but for the alleviation of the cough a ten-per-cent. solution of menthol in olive oil, or in one of the pure preparations of the higher paraffins, is often of great service.

So much want of knowledge exists as to the process of intralaryngeal injection that one may be excused for giving a short account of the manner in which it is carried out. Although at first sight it appears to be a difficult operation, it is really a very simple one and easy of performance, only requiring a little boldness. The author has performed it nearly a hundred times, and on no occasion have any of the patients vomited. The patient sits facing the light; ask him to take hold of his tongue and

pull it well forward and to take a few deep breaths. The latter not only fill the chest, but likewise render the throat less sensitive. The operator either stands or sits not quite opposite to the patient, a little to the right. The syringe having been previously filled and rendered free from air by forcing a little of the fluid along the tube, the nozzle meanwhile being turned upward, he then passes the point of the syringe over the middle of the tongue; in this way the tip of the epiglottis is avoided. The operator should endeavor to just clear the tongue and strike a line which would pass straight along the middle of the dorsum of the tongue, and when extended backward would touch the back wall of the pharynx. In this way he reaches the glottis, and gently but firmly forces the nozzle of the syringe into the trachea at the moment the patient takes a deep inspiration. The patient soon gets to know when the syringe has gone to the right spot. The piston is now moved and the fluid drops slowly into the larynx. One must catch the glottis just as a deep inspiration has been taken, for soon the patient wants to inspire again, and with the glottis plugged this is impossible; but in every case the writer has found the time sufficient in which to inject one fluidrachm of oily fluid, and, if it is desired, the operation can be repeated even five times at a sitting without evil effects; in fact, in no case have I found the least discomfort follow. The first time of applying a five-per-cent. solution of cocaine hydrochlorate may be painted over the throat to render it anæsthetic, but the after-effects are dreaded by the patient who has once had this treatment, and if the syringe be boldly handled the patient experiences no discomfort. It is the shaking hand which causes tickling and so retching. It is like swabbing out the throat. The experienced laryngologist never causes his patient to vomit; it is only the beginner who is afraid to "lay on" who does that. At first it is perhaps also advisable to employ the laryngoscope, but in using it a single movement of the patient renders all dark, and as soon as confidence is gained it may be given up. The syringe the writer employs is one known as the Beehag in Edinburgh. The barrel is of glass and the mountings and nozzle are of black vulcanite, while the finger-rings are of electroplated material. It is objected to by some that this nozzle, being of vulcanite, cannot be boiled, and so disinfected, as could be done were it of metal. This difficulty can be so far overcome by the use of antiseptics and by each patient having a nozzle for himself. This does away with all likelihood of disease being con-

veyed from one person to another. Vulcanite being softer and more pliable than metal, there is less likelihood of injuring the soft parts. When about to use, the nozzle is screwed on and the point is turned upward, the piston being slowly moved so that some of the solution is ejected and all air removed from the nozzle and barrel.

As already stated, the vehicle for the application of drugs in this way may either be olive oil or one of the paraffins, and perhaps the latter is to be preferred because it does not become rancid. The drugs employed are chiefly of an antiseptic nature and belonging to the aromatic and tar series, such as creosote, guaiacol (two per cent.), menthol and thymol (five to ten per cent.), salol (five per cent.), salicylic acid (two per cent.), carbolic acid (one per cent.), and other drugs. A useful combination is the one suggested by Professor Grainger Stewart, consisting of guaiacol (two per cent.), menthol (ten per cent.), and olive oil (eighty-eight per cent.). It is non-irritating, and 1 or 2 fluidrachms may be injected into the trachea twice a day in cases of fetid bronchitis, bronchiectasis, or pulmonary phthisis. Other drugs may be used, provided they are conveyed in a non-irritating fluid and are of such a nature as not likely to cause local injury.—*Lancet*, April 14, 1894.

#### *THE OXYTOCIC ACTION OF SALICYLIC ACID AND ITS COMPOUND WITH SODIUM.*

VINEBERG concludes an article on this subject as follows:

1. Salicylic acid and its compounds may be found useful in scanty and delayed menstruation.
2. They should not be administered to pregnant women who have a predisposition to abort or who suffer from menorrhagia and metrorrhagia.
3. Their administration should be watched carefully in all cases of pregnancy, and on the appearance of any "show," or anything resembling labor-pains, they should be discontinued.—*New York Medical Journal*, June 23, 1894.

#### *THE MORTALITY UNDER THE CÆSAREAN OPERATION IN GREAT BRITAIN DURING THE LAST EIGHT YEARS.*

R. P. HARRIS, of Philadelphia, writes on this topic in the London *Lancet* of May 19, 1894:

Before discussing the relative merits of these two operations and their risks respectively, it

may be well to consult the British records of the former for the period since the improved method of performing it was in a measure introduced in 1886, as there is evidently in London a prevailing error as to what has been accomplished in the saving of life in Great Britain. When we look back to the early record of Dr. Thomas Radford, with its eighty-four per cent. of maternal deaths, and compare it with the results of cases we have recently collected, we find much ground for encouragement, although it is evident that much more might be accomplished in reducing the death-rate. The Cæsarean operation early performed, or done before labor, upon a good subject, has a much lower rate of mortality than when the woman has been exhausted by a long labor, and especially where the numerous attempts have failed to deliver under the forceps, version, or craniotomy.

When we group together all of the cases recorded for a given country, and state how many died and how many recovered, we get a very imperfect idea of the danger of the operation *per se*. We have a general knowledge of the risk, but what we require to look into and know is why one died and another did not, and it is the acting out of this knowledge that will eventually reduce the death-rate to a moderate percentage. If men had less fear of the operation, it would be undertaken in good season and result in fewer deaths. In order to find what has been the amount of loss in England and Scotland since November 1, 1886, we made a careful search for all of the published cases, and obtained the following,—viz.: For London, twenty-two operations: women died, nine; children lost, five. For Glasgow, thirty-two operations: women died, five; children lost, (?)\*. For the provincial towns, six cases: women died, five; children lost, three; making a total of sixty operations, with forty-one recoveries and (?)\* children saved, a mortality of nearly thirty-two per cent. of the cases, London losing forty per cent. Not being able to obtain the unpublished operations, we have failed to give a full list, but the proportion would not probably be materially altered. Our record, published and not published, for the United States, commencing with 1882,—the year the improved operation was introduced,—now shows one hundred operations, with thirty-eight deaths. Out of the first fifty, twenty-

four died, and of the second fifty, fourteen died. There were sixteen operations in 1893, with four deaths. This shows that there is no difference in the results of the two countries; both are far from creditable and might be made much more so. Our cities should at least do much better, and try to make some approach towards the successes of Leipsic and Dresden. Philadelphia has made a step forward by saving thirteen women and fourteen children under her last sixteen operations; two of the three deaths were in cases having very unfavorable prognoses. When we come to examine the dangers and results of symphyseotomy, where it has been carefully and thoroughly tested, we find a more encouraging record. Professor Paul Zweifel, of Leipsic, has given both operations an extended trial, with the following results: by the Cæsarean operation he lost the fourteenth and twentieth cases out of a total of thirty; and under twenty-three symphyseotomies he lost two children, but no women. We know of no fairer comparative test than this, as the same operator made both trials. We have had forty-four symphyseotomies in the United States, with a loss of five women and eleven children, five of the latter having been already dead before the operation. Compare this with our last forty-four Cæsarean sections, and we find: women lost, twelve; and children lost, twelve. Mortality of women under symphyseotomy eleven and four-elevenths per cent., and under the Cæsarean section twenty-seven and three-elevenths per cent., or more than double. A great deal has been said about the disabilities produced by symphyseotomy, but we have found very little of any form here. As the children delivered in our country under this operation have averaged eight pounds, we propose to limit the conjugate vera to two and three-quarters inches. The Italian subossous method we believe to be the best form of operation. In primipara the Neapolitan operators secure safety to the soft parts by letting the woman in many cases deliver herself. At one time three out of four women were left to nature after the section, but now delivery by the forceps is much more common. With proper care there should seldom be any strain upon the pelvis or injury to the vagina or bladder. Women have in a number of instances been operated upon twice, and one subject in Philadelphia has been delivered of living children, once by the Cæsarean operation and twice by symphyseotomy. She would not consent to any sterilizing method being made use of. The last twenty-eight symphyseotomies in the United States proved fatal

\* We have not the results as to the children in twenty of Professor Murdoch Cameron's cases; under the other forty operations there were nine lost.

to but two women, or seven and a half per cent. It will be a long time before the Cæsean operation can accomplish this in either England or America. When we can average fifteen per cent. we may feel encouraged. Single operators like Professor Cameron may save ninety per cent., but in general practice we do not expect so low a death-rate as one in ten.

#### THE TREATMENT OF TAPE-WORM IN CHILDREN.

In the *Journal des Praticiens* for May 26, DR. DESCROIZILLES relates the case of a girl, twelve years old, who had tape-worm. She complained of pains in the head, and her appetite was capricious. Diarrhoea and constipation alternated, and traces of tape-worm were seen in the stools. The author prescribed eight grains of calomel, and three days later the same quantity of santonica. This was followed by the expulsion of fragments of the tape-worm, thus confirming his diagnosis. Dr. Descroizilles hesitated to interfere directly by radical treatment, but owing to the persistence of the parents, determined meanwhile on an immediate intervention, and the following method was employed:

1. For two or three days a special diet, such as fish or vegetable soup, eggs, milk, and moderate quantity of bread.
2. During the last twenty-four hours nothing but milk.
3. On the day before the attempt at expulsion, towards evening, a laxative enema to be given. A second enema also to be given three hours before the administration of the following remedy:
4. Ethereal extract of male fern, 2 drachms [A large dose.—ED.]; calomel, 7 grains; peppermint water, 2½ drachms; gum-arabic, 75 grains; syrup, 5 drachms; distilled water, a sufficient quantity to make a mixture of two ounces. A tablespoonful to be taken every ten minutes.
5. Several hours later an enema of castor oil (of from 6 to 7 drachms) to be given.

Dr. Descroizilles prefers the ethereal oil of male fern to quince-seeds, kousso, pomegranate, and other preparations of male fern. He prefers it also to pelletierine, the action of which is less regular. It is the best remedy for children if it is given in capsules or in gelatin and sugar.

The author is disposed to try a formula given by M. Duhourcau, who combined green ethereal extract of male fern, chloroform, castor oil, and croton oil. The chloroform renders the worm torpid, the extract of male fern is a tæniacide, and the castor oil acts as a purgative.

The author thinks it is an ingenious combination which responds to the various indications in the rational treatment of tape-worm.—*New York Medical Journal*, June 23, 1894.

#### PRESCRIPTIONS.

To allay the itching in urticaria:

R Hydrarg. perchloridi, gr. iss;  
Chloroformi, ℥xx;  
Glycerini, ℥ii;  
Aq. rosæ, ad ℥viii. M.

To be dabbed on the affected parts.

*Carbolized Collodion*.—The following formula is a good one for the preparation of "carbolized collodion:"

R Acidi carbolic, ʒi;  
Ol. ricini, of each, ℥ss;  
Collodii, ℥i. M.

For vaginismus:

R Iodoformi, gr. xv;  
Extracti belladonnæ, gr. viii;  
Ol. theobromæ, q. s. M.

For one suppository; to be used at bedtime.

Useful in alopecia areata:

R Resorcin, ʒiss;  
Ol. ricini, ℥iss;  
Sp. vin. rectificati, ℥v;  
Balsami Peruviani, gr. viii. M.  
To be applied locally.

—*Medical Press and Circular*, 1894.

#### MALARIAL CACHEXIA.

In the *Virginia Medical Monthly* for July, 1894, GUICE publishes a paper on malarial cachexia and its treatment.

It is well usually to commence the treatment of this class of patients by giving 5 grains of quinine three or four times daily for two or three days. This will rid the system of at least a portion of the germs of malaria; and especially is the quinine necessary if there be present at the time paroxysms of fever, to which a great majority of such cases are subject. Quinine will also suspend periodical attacks of neuralgia, and, in fact, any other periodical symptom. Constipation, if present, should be relieved by a simple laxative or purgative, which should be repeated *p. r. n.*

Calomel, which is so constantly and so freely given in this country, is contraindicated in malarial cachexia. It adds to the already debilitated and anæmic condition by diminishing the number of red globules of the blood. It impairs the ozonizing function of this vital fluid, deranges digestion, and impairs nutrition, and

when given to ptialism, as is so frequently done, it charges the blood with fetid and effete material, destroys the plasticity of the fibrin, and increases the proportion of water. It also stimulates and increases the waste of the tissues and otherwise adds to the burden of an already struggling system, and to this may be added the fact that there is nothing in the pathology of the disease which calls for or indicates the specific action of mercury.

The proper treatment is one that is tonic and sustaining. Such is also the rational treatment, because the general condition is that of anæmia. Whether the disease be in the stage of recent development and marked by only a few recurrences of chills and fever, or of long standing and presenting a condition of profound anæmia, enlarged spleen and liver, sallow complexion, etc., the treatment should be about the same. An excellent combination and one the author has used more frequently and more successfully than any other is the following :

℞ Quinæ sulphatis, ℥iv;  
Ferri sulph. exsic., ℥i;  
Acid. arsenosi, gr. ii;  
Ext. gentian, q. s. M.  
Divide in pill No. 40.

Sig.—1 three times daily after meals.

This prescription may be dispensed either in pill or capsule, at the option of the patient, and should be taken continuously for not less than twenty-eight days. He has found after much experience that failure to continue the treatment, whatever it be, for the above period will commonly result in a return of the original condition, and hence the rule should be rigidly applied in all cases. In severe, protracted, or advanced cases it is well to order 5 grains of quinine, to be taken once daily (morning best) in connection with the above pill for the first ten to fourteen days, after which the pill is continued alone; while this is not essential to success, he has found it useful in securing prompt and rapid improvement in such cases.

2 or 3 grains of ferri pulvis to the pill may be substituted for the dried sulphate with probably as good results in most cases, and  $\frac{1}{10}$  grain of strychnine sulphate may be added if indicated or if desired by the prescriber.

Should paroxysms of fever supervene pending the use of the pill, it may be suspended and 5 grains of quinine given three or four times daily for two or three days, after which the pill should be resumed.

Should the patient be unable to swallow a pill or capsule, the following combination will be found very successful :

℞ Quinæ sulphat., ℥i;  
Tinct. ferri chlorid., ℥i;  
Potass. chlorat., ℥ii;  
Syr. zingib., q. s. ad ℥iv. M.

Sig.—Teaspoonful three times daily in water after meals.

Where the poverty of the patient has been such as to prohibit the use of prescriptions costing so much as those above given, he has used with very good success the following :

℞ Tinct. ferri chlorid., ℥iiss;  
Liquor acidi arsenosi, ℥iiss. M.

Sig.—20 to 25 drops in water three times daily after meals.

One dose of 5 grains of quinine given daily before breakfast will add to the efficacy of the above cheap and simple combination.

Abundant experience with the virulent malaria of the southern Mississippi Valley enables the writer to speak confidently of the value and success of the foregoing treatment in all conditions of chronic malarial poisoning. In many cases, and especially the more obstinate, the disease may be remedied by the persistent use of arsenic alone (Fowler's solution, 3 to 5 minims), given three times daily after meals. He has also used with admirable success in the more obstinate cases the following :

℞ Acid. nitric., ℥i;  
Ferri sulph. (C. P.), ℥i. M.

When effervescence ceases add,—

℞ Aquæ, ℥xii;  
Quinæ sulphat., ℥i;  
Strychnæ sulph., gr. iiss;  
Potass. nit., ℥ii. M.

Sig.—Tablespoonful in water three times daily after meals.

This is an incompatible prescription, but an excellent tonic in conditions of anæmia. It is intensely bitter, and is for that reason objectionable.

In babes and young children, malarial cachexia will generally yield promptly to 1- or 2-grain doses of ferri et ammoniæ citrat., given three times daily in solution. For this class of patients medicine should be made as palatable and attractive as possible, and with this view he uses the following :

℞ Ferri et ammon. cit., ℥i to ℥ii;  
Glycerin., ℥ss to ℥i;  
Elix. simp., ℥i;  
Aquæ, ℥ii. M.

Sig.—Teaspoonful *ter in die* after taking food.

1 tablespoonful daily of febriline (2 grains to 1 drachm) may be given in connection with

this prescription for the first week in advanced cases. In the treatment of children, as in adults, the medicine should be continued for twenty-eight days. This rule is strenuously advocated for the excellent reason that very many patients will relapse if the treatment be continued for a shorter period.

The timely treatment of malarial cachexia is a sure prophylactic in the great majority of cases of that dread disease—malarial hæmaturia—which has in the last quarter of a century destroyed so many young and valuable lives. This latter disease, as is well known, develops in nearly all instances in persons who are worn down by malarial cachexia, and hence the number of cases would be enormously lessened by simply relieving the cachexia and thus robbing hæmaturia of its preferred and easy victims.

#### *HEMIPLEGIA DURING PERFLATION OF AN EMPYEMA CAVITY.*

It seems to be necessary to apologize for publishing a case in which the accident of hemiplegia occurred during the treatment of empyema, since that complication has been almost entirely relegated to the past by the abandonment of the practice of "washing out." Cases, however, arise from time to time in which the offensive character of the discharge necessitates the adoption of irrigation with an antiseptic fluid, and the following case is brought forward because it seems to suggest that the accident may easily be prevented. Here hemiplegia occurred, not during washing out, but while air laden with eucalyptus vapor was being puffed in. Fluid used for irrigation of the cavity is always warm, while the air in this case was at the temperature of the surrounding atmosphere, or possibly colder, since in taking up eucalyptus vapor it may have become chilled. This suggests that the application of cold to the pleural surface may be a factor in the production of the accident, and that in those cases that have occurred during washing out, the temperature of the fluid may have been allowed to fall below that of the body.

A man, fifty-five years of age, was admitted into the infirmary on January 13, 1891, with signs of fluid in the left side of the chest. On the 15th he was aspirated, and the cavity was found to contain pus. On February 3 the empyema was opened in the ninth space in the post-axillary line. On the 23d the cavity was washed out (it had been washed out on several previous occasions), and afterwards some air laden with eucalyptus vapor was puffed in. The patient suddenly complained of giddiness,

turned very pale, and fell back apparently dead. Pulse weak and very irregular. After artificial respiration had been kept up for a few minutes respiration recommenced and the pulse became good. He was semi-conscious for two hours after. 24th.—This morning the right arm and to a less extent the right leg are paralyzed. He is from time to time fairly sensible. He says, "Oh, dear!" The right arm becomes rigid when the patient tries to raise himself with the left. He is very restless and irritable; no facial paralysis can be made out; the pupils are equal, medium, and sluggish; the knee-jerks are brisk, the right being more so than the left; the plantar reflexes are not well marked; there is no clonus; the patient sleeps with the right eye open. 25th.—The patient speaks fairly well, using numerous words; he still seems dazed. His sister-in-law came here to see him yesterday, but he did not recognize her, though he could say a few words. He has regained considerable power in arm and leg. 26th.—The patient now seems almost as well as before the attack, although he is slightly dazed; he says that he remembers nothing; he moves the right hand and arm well, but still weak. The patient perfectly recovered, and left the infirmary with the wound healed in the course of a few weeks.

The author suggests that chilling of the pleural surface may possibly be a factor in the causation of hemiplegia. Before giving reasons for that supposition the various views of the pathology of the accident may be referred to. When the accident first attracted attention the detachment of a venous thrombus during the washing out of the empyema cavity was supposed to occasion embolism of a cerebral artery and give rise to the alarming symptoms and hemiplegia. In fatal cases, however, no such embolus was found. It was then suggested that the hemiplegia was reflex, due to some obscure inhibition of the action of one-half of the cerebrum. Against that view it was urged that the pleural surface could not be sensitive, since it had become transformed into the wall of an abscess cavity. M. Desplats, after reporting a case, suggested that, while in some the symptoms might be reflex, in others they were probably due to the toxic effect of the absorbed antiseptic, while in still others they were merely the manifestation of epilepsy or of uræmia. If epilepsy explains any case, they must be few in number, since, although epileptiform convulsions may be the main feature of this accident, the termination generally, either in death or in hemiplegia, distinguishes them from the convulsions of that disease. Uræmia

is more closely simulated; both hemiplegia and epileptiform convulsions may be present, the latter being sometimes followed by rapid death. But in the accident under notice failure of the pulse and respiration at the onset are marked features and give evidence that although there is some resemblance to uræmia, there are small, yet obvious, differences. The invariable suddenness of onset during the washing out is also against the acceptance of uræmia as the explanation.

It can hardly be supposed that the antiseptic is responsible for the hemiplegia, since that used had varied, and poisoning by the commonest antiseptics does not give rise to such symptoms; nor is it likely that these poisons would act mainly upon one cerebral hemisphere. It has been already mentioned that embolus is negatived as a cause for hemiplegia since in fatal cases no emboli have been found. If, therefore, one rejects emboli, epilepsy, uræmia, and poisoning by antiseptics, the only theory left is that the hemiplegia is due to shock. It certainly seems strange that a thickened pleural surface covered with abundant, partially organized, exudation should be able to transmit any nervous impulses to the central nervous system; but although the surface may not be sensitive to ordinary irritation, it cannot be said that a chilling of the wide vascular surface may not be capable of producing some mysterious effect upon the cerebral circulation. In the above case a few cubic centimetres of air laden with eucalyptus vapor had been puffed in when the accident occurred. Mechanical irritation by previous washing out had been harmless. It seems, therefore, reasonable to suppose that the effect of the air was not harmful from direct irritation, but indirectly through the production of cold. Possibly in every case in which the accident has occurred the antiseptic fluid has been allowed to fall below the temperature of the body. This would explain why the accident does not usually occur until the treatment has been carried on for some time. When the treatment is first commenced, more attention would probably be paid to the temperature of the fluid than at some later period in which the patient was becoming convalescent. A case referred to in the *Lancet* tends to support this view of the effect of cold. In that case .8 cubic centimetre of a three-per-cent. solution of peroxide of hydrogen had been injected, when the respiration became oppressed, clonic convulsions occurred in the right arm, the head turned to the left, and the patient died in ten minutes. A solution of peroxide of hydrogen must have been injected cold, and the quantity was too

small to have had a mechanical effect. The value of the evidence it affords is, however, somewhat diminished by the fact that the injection was not the first, but the seventh. It must also be admitted that there is one fact that seriously militates against this view of the pathology of the accident. Were the view correct, one would expect the hemiplegia to bear a constant relation to the position of the empyema. Although the hemiplegia is nearly always upon the same side of the body as the empyema, in one case recorded by M. Berbez it was on the opposite side. In the case recorded in this paper the hemiplegia was also, curiously enough, on the opposite side of the body. One is obliged to admit, therefore, that the above view as to the cause of the accident rests upon somewhat insufficient evidence, yet when necessity arises for washing out an empyema cavity it would be well to pay careful attention to the temperature of the fluid.—FISHER, *Lancet*, March 17, 1894.

#### TREATMENT OF EROSIONS OF THE STOMACH.

EINHORN, of New York, believes that the local treatment of the stomach in the presence of erosions plays a great rôle. The astringent effect of nitrate of silver solutions in similar more accessible affections led the writer to apply this substance directly to the inside of the stomach. This can best be achieved by means of the spray. It was on this occasion that he constructed the gastric spray apparatus employed by him.

The treatment is given in the following way: First, the stomach in a fasting condition is washed out with lukewarm water; when all the water has been emptied, the tube is removed from the stomach. The spray apparatus is filled with ten cubic centimetres of a one-to-two-per-mille solution of nitrate of silver, the tube end dipped into warm water and inserted into the stomach (length of tubing, fifty centimetres); thereupon the whole, or at least the greater part, of the solution in the bottle is sprayed; the bottle is then opened and the spray-tube removed from the stomach.

In fact, the good result of this method of treatment can frequently be best shown in the affection in question, for after spraying has been done several times the small pieces of gastric mucosa cease to appear. Associated with the objective symptom there appears an amelioration in the subjective feeling of the patient, the pains grow considerably less or entirely disappear, and the strength increases.

He usually combines the nitrate of silver spray treatment with intragastric galvanization, alternately applying the spray or the galvanization. The reason for the use of galvanization in these cases lies in the fact that he had such effective results in two other cases of probable erosions of the stomach, complicated with heart-trouble, by means of galvanization alone. The methodical application of intragastric galvanization combined with the spray seems to increase the curative effect.

As to diet, there is no need for being rigorous in these cases. Frequent meals, avoiding heavy vegetables, salads, and pastries, are all that is ordinarily required.

Cold ablutions, light gymnastics, out-door life, are to be warmly recommended.

Of medicaments, condurango and nux vomica are frequently, and a good, easily assimilated iron preparation always, appropriate.

Although these medicaments may be of value as adjuvants, we should rely mainly upon the local treatment.—*Medical Record*, June 23, 1894.

#### *A CASE OF RUPTURED GASTRIC ULCER SUCCESSFULLY TREATED BY ABDOMINAL SECTION AND SUTURE.*

MORSE has recently reported the following interesting case before the Royal Medico-Chirurgical Society of London.

The patient, a young woman, aged twenty, having symptoms of gastric ulcer, was suddenly seized with violent abdominal pain, followed by faintness and vomiting. The pain, which was of a burning character, commenced over the region of the stomach and gradually extended all over the abdomen. Abdominal section was performed nearly five hours after the commencement of the symptoms; the contents of the stomach were found in the peritoneal cavity. The stomach was withdrawn, and a perforation was found on the anterior surface, close to the cardiac orifice. The organ was washed out, and the perforation was closed with Lembert's sutures; the stomach was returned, the peritoneal cavity was washed out, and the wound was united. No food was given by the mouth for sixty hours, and at the end of three weeks the patient was quite well. Mr. Morse had not up to that time seen a record of any other successful case of the kind in England, though cases had been reported by Drs. Penrose and Dickson, also by Mr. Gilord, Mr. Barling, and Mr. Warrington Haward.

In the ensuing discussion, BARWELL said he

had taken much interest in this subject and had collected a large number of cases (twenty-five in all), and he had since heard of four others. One of the cases must be excluded from this series, as it was really a case of localized abscess, which was opened and drained. The abscess was no doubt due to the perforation of a gastric ulcer, though the opening into the stomach had already healed at the time of the operation. In one case, reported from abroad, the abdomen was opened from the xiphoid to the umbilicus without finding the perforation; the right rectus was then divided, the lesser omentum scratched through, and a fruitless search was made over the posterior wall of the stomach. The left rectus was then likewise divided by another transverse cut, and an opening as large as a pea was found on the anterior wall of the stomach, near the lesser curvature and the cardiac end. The patient mended slowly, the recovery being jeopardized by subphrenic abscess, localized empyema, and abscess of lung. He thought that certain lessons could be drawn from the recorded cases with regard to matters of detail in the treatment which might lead to success or otherwise. The operation should be performed as soon as possible after the occurrence of the injury. The best position to open the abdomen was some little distance to the left of the middle line, for gastric rupture was commonest nearer the cardiac end. The front wall of the stomach should then be very thoroughly searched, for though ulcer was commonest behind, yet perforation was rarer there, the usual sequence being gradual perforation of the viscus, with formation of abscess. When there was free gas in the peritoneum, a peculiar thrill could be obtained, made up of rapid vibrations, and it was often accompanied by the sudden disappearance of liver dulness. The rupture might easily be concealed by the puckering of the stomach after it had partially emptied itself through the rent. If the operation were performed later, the best guide to the rupture would be the point of chief peritonitis and effusion of lymph. In four cases the site of rupture had been overlooked, being concealed by the exudation. If the perforation could not otherwise be found, the patient might be made to drink coffee or methylene-blue solution, in order that by leakage the place of rupture could be betrayed. He did not agree that it was necessary to cut the ulcers away, for they healed as well if tucked in. The careful washing out of the stomach through the rupture was of great advantage. It was wise to eschew antiseptics in washing out the

peritoneum, for if these solutions were strong enough to be germicidal, they irritated the peritoneum or poisoned the patients, and if they were weak they were futile. He himself had used distilled water for the purpose of flushing out, and the water, if warm, served to abolish the symptoms of collapse; the best temperature was 112° F.

MR. WARRINGTON HAWARD congratulated Mr. Morse on his correct diagnosis and prompt treatment. When a perforation occurred suddenly into the general cavity of the peritoneum, the ulcer would almost certainly be found on the anterior surface of the stomach, those occurring posteriorly mostly forming adhesions. The necessity for prompt action in these cases was great, for the danger became greater the longer the case was left. Not only did the collapse become more profound, but the contents of the stomach were apt to become absorbed by the lymphatics of the diaphragm and, being carried upward, to cause a basal pleurisy or pleuro-pneumonia. Though the symptoms were usually well marked, yet the diagnosis was not always easily made. Immediately symptoms of basal pleurisy or of pleuro-pneumonia occurred, a careful exploration of the pleura should be undertaken. He was still inclined to think that the incision should be made in the middle line, for the perforation might be situated at any point on the anterior surface. If the ulcer were to be closed by suture he saw no gain in a preliminary washing out of the stomach, though he attached great importance to the thorough washing out of the peritoneum. Hot water was possibly the best thing for this, and it might, as had been pointed out, be useful in checking the collapse.

MR. PAGE referred to some cases, of which he gave the following particulars: In his first case the operation was performed forty hours after the perforation had taken place; the opening was firmly closed, but the general invasion of the peritoneal cavity by inflammation rendered cleansing impossible. In the second case the operation was performed eighteen hours after perforation, and he opened the abdomen over the site where the first pain had been felt. The perforated ulcer was close to the cardiac end of the stomach and so far from the surface that he found it practically impossible to close the orifice; the patient lived a few hours only, and afterwards it was found that leakage had taken place. In the third case it was agreed after consultation to defer operation, for there were indications that the peritonitis was purely local. After four days a drainage-tube was passed into a cavity in which

there were pus and gastric contents. Afterwards extensive exudation was found between the stomach and the diaphragm, and a second ulcer was found on the very verge of perforation on the posterior wall of the stomach. In a case in which his colleague, Mr. Pepper, had washed out the stomach he had found much difficulty to arise therefrom. He had received from Dr. Maclaren, of Carlisle, particulars of three cases of gastric ulcer treated by laparotomy, with one recovery. In the first case the perforation had occurred rather less than twelve hours previously, and there was much collapse; the patient died three days later from peritonitis. In the second case the perforation had happened nine hours before, and it did well after operation. In the third case the perforation had occurred four hours previously, and death occurred three days later from suppurative peritonitis. Dr. Maclaren attributed the fatal results to imperfect washing out of the peritoneum,—*Lancet*, March 17, 1894.

#### CRYSTALLINE DEPOSITS IN THE URINE.

Bearing in mind the etiological factors considered above, the treatment required to prevent these crystalline deposits obviously consists in preventing the formation of uric acid and calcic oxalate in the system; and, secondly, in preventing their precipitation in the kidneys. The first result is to be gained by hygienic and dietetic measures, while the second requires medicinal treatment.

The hygienic measures consist of an out-of-door life, as far as practicable, exercise, and baths. The plethoric, high-living, uric-acid victim, with his tissues crowded with waste material, evidently requires all the out-of-door exercise he can stand and warm baths to stimulate the eliminative action of the skin. The other class of debilitated, anæmic, neurasthenic subjects of uric acid or calcic oxalate are equally in need of fresh air to assist their feeble oxidizing powers, but we must be careful not to overtax their weak constitutions with too much exercise and bathing. In the consideration of diet it is especially necessary that digestion should be perfectly performed, failure in this respect causing more defective metabolism than could possibly arise from a little more or a little less of some particular article of food.

Most persons are able to digest lean meat more easily than starchy, saccharine, or fatty substances. In the latter three classes of foods, if digestion is slow, fermentation is sure to oc-

cur and the resulting acids are taken into the blood, thus lessening its alkalinity and solvent power and interfering with all the metabolic processes. In the majority of cases, therefore, a diet containing a considerable proportion of albuminous material, supplemented by succulent vegetables, will be more easily digested than one in which the starchy and saccharine elements predominate. The diet must be carefully suited to each individual case. Stimulants of all kinds must be avoided. In cases of oxaluria we must avoid the ingestion of vegetable substances containing oxalic acid, such as tomatoes, sorrel, rhubarb, onions, turnips, cauliflower, and asparagus. The free use of pure water and of milk is extremely important. As we have already seen, the urine containing crystalline deposits is almost always concentrated and highly acid. Water at the same time dilutes the urine and renders it relatively less acid.

Drinking hot water at bedtime acts very beneficially as a diuretic and gives a copious flow of urine in the morning,—a point of importance, as Roberts and others have shown that uric acid is largely precipitated in the urine in the early morning hours.

The medicinal treatment to prevent the formation of crystalline deposits of uric acid differs from that required in oxaluria and will be considered separately.

We can, as pointed out by Roberts in his recent Croomian lectures, effectually prevent by medicinal treatment the occurrence of those conditions of the urine under which alone the formation of uric-acid crystals is possible. The immediate determining cause of the precipitation is excessive acidity of the urine, and the essential indication of preventive treatment is to diminish the acidity.

Chemically, it is impossible for uric acid to be deposited from an alkaline urine and not at all likely in a neutral or feebly acid urine. A study of the normal variation of the urine at different periods of the day and night leads to the inference that the liability to uric-acid gravel rises to a dangerous intensity only during certain limited portions of the twenty-four hours. The character of the urine has been shown by Roberts to be most affected by the digestion of food, by prolonged fasting, and by sleep.

A meal, whether composed of ordinary mixed food, or of purely animal, or purely vegetable substances, produces two constant effects. It lowers the acidity of the urine and increases its volume. Conversely, prolonged fasting raises the acidity and diminishes the flow of urine. During the hours of sleep, which are

also hours of fasting, the acidity of the urine reaches its highest point and the flow of urine reaches its lowest point. The proportion of uric acid in the urine is highest during the time of sleep, but the hourly excretion is highest during the hours following a meal.

Obviously, therefore, the period when there is most risk of precipitation in the kidneys is during the time of sleep, and especially in the early morning, during the two or three hours before breakfast. In sleep, also, the horizontal position and the bodily repose make the urinary stream more sluggish and predispose to crystalline precipitation. On the other hand, during the day and the waking hours the recurrence of the meals keeps the urine at a low degree of acidity, or even renders it for a time neutral or alkaline, while the renal stream is comparatively full and rapid, and its descent from the kidneys is favored by the force of gravity. It is, therefore, only during the critical period of the latter part of the night that medicinal treatment is required. In the milder cases a single full dose of one of the alkalies taken at bedtime suffices to prevent the formation of uric-acid concretions. For this purpose the citrate of potassium is, perhaps, the best preparation to employ. The dose for an adult is from 40 to 60 grains, dissolved in a few ounces of water. In severer cases a second but smaller dose should be taken during the night.

Haig has shown also that salicylate of sodium has a decided influence in increasing the excretion of uric acid. Phosphate of sodium is at the same time a good alkalizing and laxative agent; it is also, as we have seen above, the principal natural solvent of uric acid in the urine. Roberts also points out that salines exercise a protective influence against the precipitation of uric acid. 'People who take very large quantities of common salt with their food experience a practical immunity from stone. On the other hand, it is very frequent among the children of the poor, who are fed very largely on farinaceous articles, and among the natives of India, who feed on rice. Acids and iron interfere with the solubility of uric acid and with its elimination.

A fact of great practical importance—mentioned by Haig and quoted by Osler—is that "lithia, although a beautiful solvent of uric acid in a test-tube, yet when given by mouth never reaches the uric acid at all, because it at once forms an insoluble compound with the phosphate of sodium in the blood, thus removing from that fluid one of the natural solvents of uric acid and diminishing its power

of holding uric acid in solution." Lithia waters, then, have been found useful, because the beneficial effect of the water itself exceeds the harmful effect of the lithia contained in it. This is directly opposed to the prevalent idea of the value of the lithia compounds in the uric-acid diathesis.

For a plethoric habit, the free use of alkaline mineral waters, such as Carlsbad and Vichy, is important.

In the treatment of oxaluria much less is accomplished by chemical agents. The usual tonics suitable for cases of debility are often required. Dilute mineral acids, especially nitromuriatic acid, are considered by many as almost specifics. Their beneficial action is probably accounted for by their power to correct digestive disturbances. Phosphate and chloride of sodium have a distinct solvent action on oxalate of lime. It has also seemed to me, in a few cases, that sodium salicylate has caused the crystals to disappear.

The treatment of calculus in the kidney will not be considered here, as the so-called "solvent" remedies have been found entirely unreliable, and the final resort must be to surgical methods.—*Boston Medical and Surgical Journal*, June 7, 1894.

#### CASE OF URTICARIA PRODUCED BY SANTONIN.

The following case of urticaria produced by santonin, which has lately come under the reporter's notice, presents interesting features:

A. B., a child, seven years of age, was brought to the author April 21, 1894, suffering from thread-worms, which her mother said had been present for some three years. She had been under treatment once before for this cause, but had not taken santonin on that occasion. There was nothing remarkable in the child's appearance, except that she was rather pale and flabby and had a slight cough. 3-grain santonin powders were ordered, to be taken fasting on alternate mornings for three days, preceded on the previous night by castor oil and followed by a similar dose. She had a dose of castor oil on the night of April 21, and her first powder at 7 A.M. on the 22d. On this occasion the only sign of any eruption was a red oedematous patch the size of a five-shilling piece on the left forearm, which was rather irritable, and was ascribed by her mother to an insect-bite. On the 24th she had her second powder at 7 A.M. By 8 A.M. the face was red and puffy, and in a short time the whole body and the limbs were oedematous and covered

with a typical urticarial eruption, consisting of large white wheals surrounded by a broad red areola. There was some irritation, but it was not at all intense. There was no constitutional disturbance, and by 11 A.M. the rash had almost entirely disappeared. To verify the cause of the eruption the child was given the last powder at 7.20 A.M. on the following morning, and in an hour a similar rash, if anything more intense, had appeared. The bowels were freely opened about 9 A.M., and the rash had entirely gone by 10 A.M.

There do not appear to be many cases of this interesting eruption recorded. Sievking mentions a similar example, which is the only one referred to by Crocker, and Morrow, in his interesting work on drug eruptions, mentions the above case and a number of others recorded by Hubert, in which the administration of santonate of sodium was followed by an eruption of pin-sized vesicles in the trunk and limbs. Underwood also relates a case in which the taking of 5 grains of santonin in an adult was followed by a morbilloid cuticular efflorescence and a punctiform rash on the buccal and pharyngeal mucous membrane. It appears, therefore, that the santonin idiosyncrasy is rare, and that the eruption may vary in character, is accompanied by little or no constitutional disturbance, and rapidly disappears, leaving no ill effects.—G. STEWART ABRAM, *Lancet*, May 12, 1894.

#### HOW TO GIVE PILLS TO CHILDREN.

BOND, in the *Virginia Medical Monthly* for July, 1894, states that the inability of smaller children to swallow pills without chewing them up renders the administration of certain ill-tasting drugs to such patients very difficult, and really in many cases becomes a very serious hinderance to necessary treatment.

This fact is especially striking when we consider the treatment of malarial fevers in small children by means of quinine. The hypodermic method and administration by the rectum are too unhandy for general use. Application through the unbroken skin is too uncertain and inconvenient. The drug must be given by the mouth in nearly all cases, or not used at all. Solutions of quinine in acidulated water are, indeed, most efficacious in the cure of the disease, but the philosophy of the Stoics has not yet become a fad among the grown folks of America, and we need not expect children to practise its teachings. Quinine may be dissolved in tincture of iron, and, when syrup is added, the combination of nasty things

will sometimes be taken without much objection by older children; but iron is often unnecessary or contraindicated in these cases.

The administration of quinine in bulky mixtures of substances which cover the taste of the drug is open to grave objections, for it may well be questioned whether the large quantities of licorice, yerba santa, chocolate, etc., are not positively injurious in many cases to the already enfeebled stomachs of young patients, or even of older ones, ill with severe malarial diseases.

Tablets of chocolate containing definite quantities of tannate of quinine have found some favor with physicians and are greatly enjoyed by certain children. They, however, are open to the objection that tannate of quinine is not a sufficiently active preparation of the drug to warrant reliance upon it in severe cases.

With some confidence of receiving an attentive hearing he recommends a method he has found efficacious in his own practice. The quinine sulphate is ordered in pill form with dilute acid, generally aromatic sulphuric acid, and the mother of the patient is directed to break up each pill and mix it with a little brown sugar. This is put upon the tongue dry, and a mouthful of water carries it into the stomach. Sometimes sweet chocolate is broken up and used instead of brown sugar, or it is taken into the mouth before and after the bits of quinine pill and sugar. A stick of licorice root may be used in the same way. In this way a very little of the masking substance suffices at each dose. The pill of quinine sulphate made with aromatic sulphuric acid is not only very soluble, but also in its smallest possible bulk.

It will readily be seen that by means of the pill broken with brown sugar or other masking agent, any drug or mixture of drugs which can be made into pilular form may be administered to children with facility. Since it occurred to the author to try this method he has never felt the need of mask mixtures for such prescriptions. Moreover, the mothers of the children take kindly to the plan.

#### INFANTILE THERAPEUTICS.

LUZET (*Arch. Gén. de Méd.*, June, 16, 1874) gives a critical review based on the work of Legendre and Broca. The special points really consist in the phases of development in the infant, in the special feature of disease which here proceeds rapidly towards aggravation or recovery, and in the physiological peculiarities of more active metabolism, of more

rapid absorption and circulation, of intact emunctories, and of a more impressionable nervous system. In regard to feeding, the regular increase in weight must be relied upon. A tuberculous nurse must not be employed, for if bacilli do not pass out with the milk, toxins can; in addition, the milk is less rich in fat and casein. Overfeeding the nurse must be avoided. Of course, artificial feeding is only a method of necessity. The milk should be sterilized by means of steam under pressure. The therapeutic bath is used to reduce temperature; the bath is then gradually cooled down from 2° F. below the child's temperature to 30° F.; it is useful in enteric fever, severe scarlet fever, and cerebral rheumatism. The bath with increasing temperature is of value in collapse, such as occurs in diarrhoea; it may also be a vehicle for certain medications. More strictly therapeutic measures are then discussed in the following order:

1. Evacuating medication. The stomach-tube is very useful, as well as intestinal injections and emetics. Apomorphine is dangerous.

2. Promotion of excretions. The best diuretic is water. Large rectal injections of cold water constitute a good method of inducing diuresis. In uræmia, icterus, and all intoxications large injections are useful. Cold baths are also of service in increasing renal excretion. Digitalis is well borne by children. Diaphoresis is best obtained by physical agents,—heat, wet sheets, hot drinks. Diuresis is more efficient than diaphoresis.

3. Sleep should never be interrupted in disease, with very few exceptions. It may at times be necessary to induce sleep. This may sometimes be done by removing something which interferes with sleep. Physical agents are again the best means, such as tepid baths, etc. Opium requires caution; chloral is useful; bromides and antipyrin may be of service.

4. Fever is controlled by external agents,—baths, etc. Quinine, antipyrin, and sodium salicylate may be useful adjuvants.

5. Food is the best tonic. Alcohol is the best stimulant.

6. Antiseptic medication plays a very important part in infantile therapeutics. Carbolic acid in any form must be avoided. The mouth should be cleansed with alkaline lotions. Glycerin is a good non-fermentable medium. Antisepsis of the stomach may be procured by washing it out, and, together with the intestine, by the use of bismuth, salicylate, salol, etc. Calomel is a powerful intestinal antiseptic.

Antisepsis of the large intestine is obtained by means of irrigations containing naphthol, etc. It is indicated in typhlitis, appendicitis, membranous colitis, etc.—*British Medical Journal*, June 30, 1894.

#### PARA- AND ORTHOCHLORPHENOL IN TUBERCULOUS AND OTHER DISEASES.

N. SIMANOFFSKI (*Vratch*, No. 8, 1894) has used solutions of monochlorphenol in glycerin in the strength of five per cent., ten per cent., and twenty per cent., and points out as special features of these very powerful disinfectants that they do not irritate the mucous membrane, even if applied in a twenty-per-cent. solution, that they form no stable combination with the tissue albumins, and that they are therefore able to penetrate into the depth of the diseased organ. The tuberculous cases treated were mostly very advanced and serious affections of the throat with impairment of voice and difficulty in swallowing. In one case there was, besides these symptoms, a tuberculous ulcer at the root of the tongue; in another a similar ulcer on the whole posterior wall of the pharynx and part of the nasopharyngeal region. All cases, without exception, even including the last one, in which there was a very advanced affection of the lung, improved quickly under the local treatment with monochlorphenols; the ulcers became clean and showed a tendency to heal, and all the accompanying symptoms disappeared. Equally good results were obtained in chronic thickening and hyperplasia of the mucous membranes, which disappeared after a few applications of the same solutions. Simanoffski is of opinion that the monochlorphenols will find a large field of application in diphtheria, etc., and he unhesitatingly recommends them in laryngological practice in preference to iodoform, pyoktanin, menthol, etc., especially as they also possess anæsthetic properties.—*British Medical Journal*, June 30, 1894.

#### TREATMENT OF NIGHT-SWEATS OF PHTHISIS.

CONKLING writes a valuable paper on this topic. As the result of wide experience he finds aromatic sulphuric acid is at times a useful remedy. It possesses some marked disadvantages: it could not be used for any length of time; it frequently produced constipation; and it interfered, after a time, with some special lines of treatment devoted to the pulmonary lesion.

The remedy was given in sweetened water; or, if not objectionable to the patient, in water alone. The dose used was 10 to 15 minims at bedtime (one dose); or it was given in three doses, in 7 to 10 minims each dose. The first of these was given in the late afternoon, the second in the early evening, and the third at bedtime. The latter method was found the better.

This remedy diminished the sweating in all the administrations, but stopped it in less than half. But it never stopped the sweating at once; diminution always came before cessation.

Camphoric acid was found to be very uncertain in its action. Its successes and failures did not seem to bear any relation to particular cases. It sometimes would succeed where before it had failed. It had no after-effects.

The dose given was 30 grains in water at bedtime.

This remedy had a large number of failures. It diminished the sweating in a very few, and was successful in a little over one-third of the administrations; but even in some of these the perfect cutaneous dryness of some other remedies was not noted.

Chloralamid was found to be a very important and valuable remedy. Mention of its use as an anidrotic has appeared in print several times. The author's own knowledge of its power in this direction was obtained by accident soon after its introduction into the American market. The drug was being used in tubercular patients as an hypnotic. The patients, after giving their answer as to the effect of the "sleeping medicine," would frequently say that the sweating was less or absent. This was repeated so many times that finally the drug was tested. It was found to produce sleep, stop cough, and stop sweating. It had no disadvantages, either producing the desired result or being inert.

Chloralamid was given in one dose of 30 or 35 grains, at bedtime, either in powder or in the form of Schering's elixir.

The remedy diminished the sweating in less than one-fourth of the administrations, failed in about the same number, and succeeded in over one-half. Even in severe cases the first administration was frequently successful.

Muscarine was the least successful of all the remedies; it had no after-effects. Indeed, judging from the action of the chief members of its family, one would expect rather some favorable vascular or nervous action.

It was given in pill form at bedtime, in doses of  $\frac{1}{10}$  grain.

This remedy stopped the sweating in only twenty per cent. of the administrations, failed absolutely in forty per cent., and diminished it only slightly in the remainder.

The writer's experience with oxide of zinc showed that there was no particular idiosyncrasy required on the patient's part to produce the good results. It was also interesting to note that the element of time was not needed. It was not necessary to use it in repeated doses to produce the effect desired; in many cases the first administration would stop the sweating. But if the first few doses were not successful, the latter ones seldom were. Another feature in this drug was that, when other remedies had failed, the first dose of the oxide of zinc would be frequently successful; it had no after-effects.

It was given in pill form at bedtime in doses of  $2\frac{1}{2}$  grains.

This remedy stopped the sweating in two-thirds of the administrations; in the others it somewhat reduced it or failed entirely.

Agaricin was the most successful of all the drugs; it produced most excellent results in young subjects. Under its use the skin remained in a dry condition, without suspicion of any kind of cutaneous activity. It was very successful in cases where, during its use, the sweating had disappeared, and had returned after the drug had been discontinued for a time. Repetition did not weaken its power. Of all the remedies, it acted best in the first few administrations. Subsequent ones sometimes failed. It can be used for any length of time and has no disadvantages.

Agaricin was given in pill form,  $\frac{1}{2}$  grain; one pill at bedtime, or a pill late in the afternoon, and a second in four or five hours.

This remedy diminished the sweating in one-eighth of the administrations, stopped it in three-fourths, and failed in the remainder.

The study of cases has shown that atropine and belladonna are not the best anidrotics; they are frequently used in a routine manner; in these cases some difference in their action was noticed. Atropine is a powerful heart drug, and acts on that cardiac nerve the branches of which it is not always best to stimulate in pulmonary tuberculosis; it has after-effects. Restlessness, insomnia, disturbing dreams, and modifications of secretion were noted. Even the good effects of checked perspiration were sometimes counterbalanced by these disadvantages.

It was given in tablet or in solution, in doses of  $\frac{1}{80}$  grain or less.

This remedy diminished or stopped the

sweating in over two-thirds of the administrations.

Tincture of belladonna possesses some of the disadvantages of atropine; delirium was caused by it (idiosyncratic). The distressing symptoms of laryngeal tuberculosis were increased by it. Diarrhoea was increased where intestinal ulceration accompanied the throat lesion.

The dose used was 7 or 10 minims, commencing in the afternoon and giving two or three doses.

This remedy stopped the sweating in seventy per cent. of the administrations, diminished it in twenty per cent., and failed in ten per cent.

The above brief report deals with some of the points recorded during the treatment of the cases. The smallest possible dose was always used. At present with other remedies the same line of investigation is adopted. But with the above, if the first few administrations do not stop the sweating, another drug in the list is at once tried. Agaricin has given the best results; it must be of the purest quality.—*Brooklyn Medical Journal*, July, 1894.

#### THIOL IN ERYSIPELAS.

Following Ridder's recommendation, N. K. RUDNEFF (*Meditsinskoie Obozrenie*, No. 13, 1893) tried thiol, in the form of a twenty-to-forty-per-cent. aqueous solution, in fifteen cases of erysipelas,—fourteen of the face and one of the leg; all in soldiers. The affected regions, as well as an adjacent healthy zone (about two fingers'-breadths wide) were painted five times daily until the appearance of desquamation, and even, though less frequently, for one or two days more. As adjuvants, he employed (a) calomel, 10 grains, internally, just after admission; (b) sulphate of quinine, 10 grains twice daily (only when high fever is present); (c) camphor, 10 or 15 grains a day, internally, in the shape of emulsion (as recommended by Pirogoff). (See *Provincial Medical Journal*, February, 1891.) In three cases the disease was cut short within twenty-four hours; in eight others, treated like the preceding with a forty-per-cent. solution of thiol, the patients were practically cured in from two to four days; in four earlier cases, in which a twenty-per-cent. solution was applied, there occurred relapses, the disease permanently subsiding after a subsequent application of the stronger solution. On the whole, Rudneff is satisfied with thiol, its advantages including a complete absence of odor and of toxic and irritant properties. The disadvantages are limited to its staining linen, inducing an intense blackish

discoloration of the skin, and being rather expensive. The latter circumstance prevents a routine thiol treatment of erysipelas in hospitals. The author himself has recourse to thiol only in cases in which a corrosive-sublimate treatment (painting with a 1 to 1000 or 500 aqueous solution) fails to cut short the disease. To judge from Rudneff's sixty cases treated with the bichloride, the latter represents the most efficacious remedy for erysipelas after thiol. —*British Medical Journal*, June 30, 1894.

#### PIPERAZIN AS A URIC-ACID SOLVENT.

DR. K. BOHLAND (*Therapeutische Monatshefte*, May, 1894) has sought a patient who persistently exhibited uric acid as a sediment, in order to test upon him the solvent powers of piperazin. He found such a one in a leukæmic man, whose ratio of white to red blood-cells was as 1 to 3. His urine showed for months a persistent considerable uric-acid sediment.

Piperazin did not change the daily quantity of urine passed, but perhaps slightly lessened its acidity. The quantity of uric acid excreted in twenty-four hours remained the same during the piperazin treatment as it was during the administration of bicarbonate of potassium or when no uric-acid solvent was administered. This result agrees with those of Biesenthal and Schmidt, Levison, Dapper, and others.

Bohland reviews the whole subject at some length, and concludes that the treatment of uric-acid concretions in the kidneys and bladder, in the uric-acid diathesis, with piperazin, is entirely without favorable prospect. Existing concretions can neither be dissolved nor can their enlargement be checked by it.

#### IZAL.

N. A. BLAGOVESHCHENSKY, of Moscow (*Vratch*, No. 5, 1894), states that his experiments fully support Klein's high opinion of the antiseptic properties of izal. (See *British Medical Journal*, October 7, 1893.) A three-per-cent. aqueous emulsion destroys the cholera vibrio in fifteen minutes, and a five-per-cent. emulsion in two minutes. Eberth's typhoid bacillus is killed by a three- or five-per-cent. mixture in three minutes, while pyogenic microbes lose their vitality after a few minutes' contact with a two-per-cent. emulsion. Anthrax bacilli resist a one- to five-per-cent. mixture, but perish fairly quickly when treated with a ten-per-cent. mixture. Dressing and suture materials and hands infected with pyogenic streptococci and staphylococci can be sterilized

with izal emulsions in a satisfactory manner. The author declares that "even very strong emulsions of the substance are absolutely harmless." Referring to this paper, P. I. Diakonoff, of Moscow, points out (*Vratch*, No. 5, 1894) that commercial specimens of izal are found to vary in their chemical composition, while another disadvantage of the new disinfectant consists in its being non-transparent. —*British Medical Journal*, June 30, 1894.

#### TREATMENT OF DIABETES WITH FLUID EXTRACT OF JAMBUL E CORTICE.

DR. LENNÉ (*Therapeutische Monatshefte*, May, 1894), who had previously reported encouraging results from the use of powder prepared from the fruit of *Syzygium Jambolanum*, has now tried the fluid extract of the bark, according to the method proposed by Vix. 15 grains were given in water three times a day from one to two hours after meals.

On February 14 to 15 the patient passed 4250 cubic centimetres urine, specific gravity 1034, containing a trace of albumin; 5.1 per cent. sugar (216.75 grammes); 3.1 per cent. urea (131.75 grammes); large amount of acetic acid.

Under treatment the patient's weight increased from 43.950 kilogrammes to 45.300 kilogrammes on March 17. The volume of urine at that time was 3000 cubic centimetres; the specific gravity, 1031; the percentage of sugar, 3.6 (108 grammes); the percentage of urea, 2.6 (78 grammes). The diminution in the amount of sugar was, however, not constant, reaching as high as 5.3 per cent. on February 22, and again 4.5 per cent. on March 16. Lenné concludes justly that not the slightest influence of the agent upon metabolism can be recognized. For his part, he thinks that the fluid extract from the bark exerts just as little influence upon the sugar-excreting process of diabetes as does the powdered fruit.

#### THE INFLUENCE OF SUGAR AND TOBACCO ON MUSCULAR EFFORT.

In 1892 an important series of experiments were undertaken by DR. WARREN LOMBARD upon the influence of tobacco on muscular effort. The same subject has been investigated by DR. VAUGHAN HARLEY, and the results of his observations are recorded in the first part of the *Journal of Physiology* for the present year. Dr. Vaughan Harley agrees with Dr. Lombard in considering that the amount of work done by the same set of muscles at different times

of the day undergoes periodical variation ; so we may accept as a fact that there is a diurnal rise and fall in the power of doing voluntary muscular work, in the same way as there is a diurnal rise and fall in bodily temperature and pulse. It is remarkable, however, that instead of the greatest amount of work being done, as might have been expected, on rising in the morning after a good night's rest, it is found that at 9 A.M. the smallest amount of work is accomplished, the powers of doing muscular work in Dr. Harley's case increasing each hour up to 11 A.M. Immediately after lunch there is a marked rise, followed an hour later by a fall ; while again an hour later, or about 3 P.M., the amount of work accomplished reaches its maximum. Then, from some unexplained cause, there is a notable fall at 4 P.M., which is succeeded by a rise at 5 P.M., after which a progressive fall takes place during each successive hour until dinner. Even during a prolonged fast more work was capable of being executed from 11.30 A.M. to 4.30 P.M. than at 9 A.M. Dr. Harley admits, however, that further experiments are required to determine this point satisfactorily. It was found in his experiments on the muscles of the middle finger, that, in corroboration of a well-known physiological fact, regular exercise caused increase in the size of the muscles brought into play, and at the same time up to a certain point rendered them capable of performing more work. Sugar, taken internally, proved to be a muscular food ; since, when taken on an empty stomach, there was on that day an increase of 25.6 per cent. in the work done by the left middle finger, while the right middle finger showed an increase of no less than 32.6 per cent. Dr. Harley varied the experiment of administering sugar in many different ways, but always with the same result : the vigor of the muscles was always augmented. The influence of tobacco was not so marked in Dr. Harley's experiments as in those of Dr. Lombard. Dr. Harley considers that moderate smoking, in one accustomed to it, neither increases the amount of work nor retards the approach of fatigue. It perhaps slightly diminishes muscular power and hastens the onset of fatigue. Dr. Lombard holds that the use of tobacco has a powerful influence in this direction. Such experiments as these, even when no absolutely definite result is arrived at, are of importance, and if carried out with due precaution against error, in a large number of men, would undoubtedly constitute the most satisfactory basis on which a sound system of training should be carried out.—*Lancet*, May 12, 1894.

#### VALUE OF OPIUM IN THE LARYNGEAL STENOSES OF CHILDREN.

DR. CARL STERN (*Therapeutische Monatshefte*, May, 1894) recalls the well-known fact that the difficulty in breathing in stenosis of the larynx in children is greatly aggravated by sleeplessness and fright. For this reason he has been led to treat these cases with opium and his results have been so gratifying that he believes the remedy should receive more extensive employment. He uses it in cases—whether in diphtheria or without existing throat-affection—in which the hoarseness, the barking cough, the stridor, the cyanosis, and finally the sucking in of the xiphoid process and lateral portions of the thorax point unmistakably to stenosis of the larynx. He reports several cases in which the use of opium averted an apparently necessary tracheotomy.

Stern gives from 2 to 5 drops of the tincture of opium, according to the age of the child and the intensity of the symptoms, the dose being renewed according to the result obtained. For the most part he gives a child a year old 3 drops in a teaspoonful of sweetened water. If no result is obtained, after half an hour two drops more are given. If the symptoms become more severe, the propriety of further medication or tracheotomy must be considered.

#### A CASE OF OBSTINATE MEMBRANOUS ENTERITIS.

*La Presse Médicale* for May 19 gives the following treatment, which was successfully used in the case of a young woman : 1. Every morning an energetic general friction with a glove saturated with oil of turpentine. 2. Twice a week a hot bath in which a pound of sea salt and nine ounces and a half of sodium carbonate have been dissolved. 3. Each morning, taken slowly in a recumbent posture, an enema, as hot as possible, of nine ounces and a half of boiled water in which half a drachm of borax has been dissolved. 4. Every day, before the mid-day meal, nine grains of quinine sulphate. 5. The exclusive use of beer, milk, and Evian water.—*New York Medical Journal*, June 23, 1894.

#### A NOTE ON THE THERAPEUTICS OF DIURETIN.

MCPHEDRAN contributes the following note on this subject to the *Canadian Practitioner* of June, 1894 :

It would seem probable that diuretin is effective only within a very narrow range of morbid condition ; that when the heart has failed be-

yond a certain degree, it will not respond to the stimulus of diuretin. This seems to be true, at all events, in my own cases, in all of which its use has been temporarily more or less effective, but only temporarily; as recurrence of the dropsy and cardiac failure was little, if at all, benefited by a repetition of the drug. Diuretin is, unfortunately, a patent remedy. Its composition is known, but the process of manufacture is secret. The salicylate of theobromine and sodium is composed of the same ingredients, but is much less agreeable to take, and its effect, so far as the writer has tried, is not so satisfactory, possibly from its being less soluble. In some cases diuretin causes headache, nausea, and a feeling of depression, probably due to the salicylic acid in its composition.

In concluding, the writer states that while diuretin is not a reliable remedy, yet in suitable cases its beneficial effects are so decided as to render it worthy a trial in those distressing cases in which the heart is failing and dropsy increasing. Even if its good effects are only temporary, they are in some cases so satisfactory that the respite given amply repays its administration. Most drugs are temporary in their effects, and we do not refrain from their use on that account. It is probable that it will be found most useful in chronic diseases of the heart-muscle, with disease of the kidney, as in arterio-capillary fibrosis; less so in purely renal cases. It may sometimes prove useful also in valvular disease with ruptured compensation. In ascites from hepatic affections and in pleural effusions it will probably have no effect.

Like all patented preparations, diuretin is unnecessarily expensive, about twice the price of the salicylate of theobromine and sodium. It is to be hoped that an equally useful preparation without the patent may soon be placed within our reach.

#### CHLORALOSE.

CAPPELLETTI (*Mem. dell' Acad. delle Scienze Med. in Ferrara*, lxvi., No. 4) gives the results of experiments with chloralose. These are as follows:

*General Action.*—In frogs, small doses increase the reflex excitability. Medium doses cause diminution of voluntary movement, the power to perform which disappears after an amount varying between five and ten milligrammes has been given. In mice, a dose of 10 centigrammes per kilogramme produces exaggeration of reflexes, lessens sensibility to pain, and abolishes the power to perform voluntary movement; tonic and clonic convul-

sions are also produced. Smaller doses produce similar but less marked symptoms. In rabbits, chloralose produces first a stage of excitement, which gives place to sleep, with a diminution of voluntary movements and exaggeration of superficial reflexes. Convulsions are seen similar to those appearing in the rat. In dogs, sleep is preceded by a period of excitement, during which the animal staggers about and is insensible to his surroundings. The reflexes are exaggerated and the sense of pain is abolished. When the sleep is not profound, convulsions are a prominent symptom. In dogs, a dose of 15 centigrammes per kilogramme is enough to induce sleep. In frogs, the frequency and force of the heart-beats are not altered by small doses; with large ones the beat becomes slower and less powerful. In rabbits and dogs, the carotid pressure is not affected by small or medium doses, and it is only slightly lowered by large ones; the heart-beats also are practically unaffected; the respiration is slowed, and in the case of large doses its rhythm is somewhat altered. In rabbits and dogs, the temperature is lowered often to a marked extent.

*Action on Man.*—The action of the drug was tested only on asylum patients suffering from insomnia, the dose given at the commencement being about 3 grains. The sleep produced was, as a rule, calm and uncomplicated, the dose necessary varying according to the patient. In cases of slight insomnia 3 to 6 grains are sufficient, but in severe insomnia 12 to 18 grains may be necessary. Sleep came on in about half an hour after taking the drug, and was preceded by a period of pleasant drowsiness; hysterical patients were found particularly susceptible. The smallest doses mentioned produced a sleep of six to seven hours; large ones, on the other hand, often produced convulsive attacks, without sleep. As an hypnotic, chloralose is particularly efficacious if given in the evening.

*Action on Reflexes, Tactile Sensibility, Pulse, Respiration, and Temperature.*—During the sleep the reflexes are generally wanting, but in certain cases the contrary is seen. The appreciation of tactile and painful sensation remains unaltered, as do the pulse, respiration, and temperature. On the disease producing the insomnia, chloralose does not, as a rule, produce much effect. Some cases, however, improved markedly under its influence, but this may be merely a coincidence. In most cases the sleep is indistinguishable from physiological sleep. However, in cases in which large doses have been given, abnormal symptoms

may arise, among which may be mentioned flushing of the face, epileptiform convulsions, tremors resembling those of paralysis agitans (during the sleep), and headache, uncertainty of speech, and urticaria (after return of consciousness). Care must be taken, therefore, to give only small doses to the feeble or hysterical.

*Elimination.*—Chloralose, as such, does not appear in the urine.—*British Medical Journal*, June 9, 1894.

#### FIFTY CASES OF RECTAL SURGERY.

RICKETTS (*Mathews's Medical Quarterly*, July, 1894) gives detailed statistics concerning fifty cases of rectal surgery, and concludes from these cases that in such operations it is necessary to have the patient completely anæsthetized, and that the use of chloroform is the quickest and best means of securing this end. Cocaine is not satisfactory. This drug should, however, be given the preference in minor surgery.

As to the clamp and cautery, he relies wholly upon them in removing hemorrhoids of any size or number, it being the safest and quickest method, and so followed by speediest convalescence.

An application of the actual cautery to all ulcers and fissures at one sitting has been the most efficacious means of destroying them that he has found.

Division of fistulæ with the bistoury has not failed in any attempt to obliterate them, without in a single case destroying the function of the sphincter.

Of eight cases of ischio-rectal abscess, five occurred at the time immediately following an acute gonorrhœa. Fistulæ resulted, and were operated upon in each of the eight cases. He believes that acute gonorrhœa is the most frequent cause of ischio-rectal abscess in the male. However, an acute inflammatory process, due to any cause, is as likely to produce an abscess, the contents of which may escape into the rectum.

It is interesting to note that thirty of the cases were either tubercular or syphilitic. In the four cases of carcinoma the disease had progressed to such a degree as to render it unwise to attempt a radical operation, except towards the last, when colotomy should have been resorted to, but was refused.

Case No. 50 was unique, in that, falling from a table, a piece of ducking one and a quarter inches square was driven along the side of the rectum by a chair leg. The foreign body remained concealed for five months without de-

tection, until the writer was consulted. A portion of the sphincter was torn away, but its office remains good at the present time.

The average loss of time is but little for surgical cases of this nature.

#### TREATMENT OF SCORBUS IN INFANCY.

CARR (*Medical Record*, June 30, 1894) records an interesting case of scorbutus in an infant, in which the following treatment met with entire success:

Give at once fresh milk, beef juice, and fruits or vegetables. Orange is liked by almost all children, and is greedily devoured. When orange does not agree or is distasteful, other fruits or vegetables will do as well.

The relief of the symptoms of scorbutus is so rapid under this regimen that medicinal agents are seldom needed, except as here indicated.

Local applications of evaporating lotions to the swollen parts seem to afford relief. An opiate is useful in allaying pain and irritability and in checking severe diarrhœa. Stimulation is frequently needed to support the system. Iron is of service to combat the anæmia, but it does not hasten recovery if the dietetic management is neglected. Cod-liver oil and phosphorus are valuable in the cases where scorbutus and rachitis coexist. Sunlight, fresh air, and good hygiene are powerful aids to recovery. The fractured bones are to be treated mechanically until the antiscorbutic diet has had its effect.

#### INTERNAL HEMORRHOIDS.

DUNDORE (*Mathews's Medical Quarterly*, July, 1894), after an exhaustive paper on this subject, concludes as follows:

1. The ligature is the safest method of operating for internal hemorrhoids, as there is less likelihood of its use being followed by hemorrhage, stricture, or ulcers.

2. The clamp and cautery cause less pain, shorter convalescence, and are less likely to be followed by retention of urine than when the ligature is used; but hemorrhage and stricture of the rectum may very often follow their improper application.

3. The practice of Whitehead's method should be limited to those cases in which the entire circumference of the anus is involved. In ordinary cases of one or more hemorrhoids it should never be used, as it is liable to be followed by severe after-effects, and at best could produce no more radical result than the clamp and cautery or ligature.

4. Simple dilatation of the sphincter, in-

jection of carbolic acid, and Manley's method are simple palliatives, and their use is very limited.

5. There is no single operation which is available in all cases. Experience alone should suggest the most efficient method of treating each individual case.

#### *IDIOPATHIC TETANUS TREATED WITH SUBCUTANEOUS INJECTION OF ESERINE SULPHAS.*

In a communication to the *Indian Medical Gazette* for June, 1894, GAZDHAR reports the case of a Hindoo of the laboring class who found one morning on awakening that he was unable to open his mouth completely and that his whole body was stiff. Ascribing this to the effects of sleeping in the open air, he went to his work as usual; but he soon began to experience shocks passing through the body which rendered work impossible, and he returned to his house. The stiffness of the body increased and the spasms came at shorter intervals. Gradually the jaws became locked up completely and he could take nourishment with difficulty. The ordinary run of medicines proving ineffectual, the reporter tried hypodermic injections of eserine sulphas in  $\frac{1}{12}$ -grain doses. The effect was marvellous; for after two or three injections the tonic spasmodic condition of the body became less marked, the intervals between the clonic spasms increased, and the stiffness of the jaws lessened considerably. Within a week from the commencement of the injections the spasms had completely disappeared and the mouth could be opened to its full extent. About a dozen injections were performed in all, and the patient made a complete recovery.

#### *BLOODLESS OPERATION FOR THE EX- CISION OF HEMORRHOIDS.*

BISHOP (*Mathews's Medical Quarterly*, July, 1894) claims for the above operation harmlessly controlling the hemorrhage while excising the tumors and redundant folds of the rectum, and the perfect and undisturbed coaptation of the edges.

The following is the *modus operandi*: With a lateral or dorsal decubitus, as convenience or expediency may decide, and with an aseptic perineum and dilated sphincter, gently and smoothly clamp the base of the hemorrhoids with suitable forceps, so as to parallel the approximated surfaces and free them from folds

and adjacent healthy tissues, apply on either side a sufficient length of rubber tubing five or six millimetres in diameter, with a lumen of one millimetre, and secure with aseptic catgut after the general manner of the quilled suture. To assure accuracy of adjustment, the pieces of tubing should be of the same length and have corresponding marks six or eight millimetres apart, indicating the locations for the sutures. Each tube should have its extremities hermetically sealed by the sutures there tied, thus adding a degree of pneumatic elasticity to that possessed by the rubber. All the sutures should be preapplied or tied beforehand to one of the pieces of tubing, with threaded needles in each of the opposite loops, ready for transfixing the tissues and tying over the other piece of tubing. Remove the forceps, and excise the tumor close to the rubber tubing with flat scissors. The fixation of the tubing may be varied by using one piece doubled upon itself and drawn together with a continuous suture, made to assume an advancing figure of eight, or double spiral, by passing the needle always close to the forceps and the thread always encircling the tube from below upward; the perforations then are in one line and the tension evenly distributed. Where many stitches are to be taken it saves the time consumed in tying. This completes a bloodless operation, for the elasticity of this welted suture supplies sufficient pressure to prevent all hemorrhage, and maintains in perfect and uniform contact the margins of the wound without endangering by local asphyxial and necrotic conditions consequent on rigid clamping, and without interfering with the plastic exudation of repair by first intention.

The further dressing of the wound consists simply in passing a strip of moist borated gauze into the rectum, leaving an end protruding from the anus. The catgut sutures soften in due time and permit the tubing to pass away, while the flexibility of the latter has adapted itself to the environments with the minimum of annoyance to the patient.

#### *APPENDICITIS STRICTLY A SURGICAL LESION.*

After reporting two cases in his own practice, proving his theory, WYETH concludes a paper with the above heading, published in the *New York Medical Journal* for June 30, 1894, by the statement that, given a surgeon of experience, a clean operator, who, with the minimum of traumatism to the intestines or contiguous viscera, can remove a diseased appendix, it would be better for exploratory laparotomy

to be done in every instance within the first twenty-four hours of the disease.

On the contrary, were he himself the subject of an attack, and were he not sure of his surgeon, he would keep flat on his back, quiet peristalsis and voluntary motion with morphine, and take the chances of resolution, encapsulation by adhesion, or rupture into the intestines. If there is one particular operation an inexperienced man should in all conscience avoid, it is this.

#### DISINFECTION.

SAGE (*American Medico-Surgical Bulletin*, July 1, 1894) discusses the various methods of disinfection as follows :

Conditions of temperature and moisture are to be considered in the application of disinfectants to infectious material. A moist condition of the mass to be disinfected facilitates diffusion and allows prompt penetration by the disinfectant.

A high temperature increases the activity of chemical disinfectants, aids solution, and renders the mass permeable, and should be employed whenever the conditions will permit. Various infectious matters are best destroyed by special measures or means adapted to each individual case. Sputa and sputa cups are best disinfected by steam ; excreta and discharges may be effectually treated by milk of lime ; while water-closets, cesspools, vaults, and stables should receive a liberal application of chloride of lime.

The sick-room, when vacated, may be thoroughly purified by scrubbing the floor and wood-work with a solution of corrosive sublimate. Furniture can be wiped off with the same fluid and afterwards washed with soap and water.

In connection with the application and use of disinfectants, it is proper to review briefly the special action and deportment towards infectious material of some of the best known of the large class of disinfecting agents.

Fire is one of the best disinfectants. Unfortunately, however, its application is limited to the destruction of valueless articles in cases of extreme urgency, demanding prompt and total destruction not only of infectious matter, but also of the means or agency of its conveyance. A necessity might also exist for the use of fire, where heavy mattresses, feather and straw beds, or heavy quilts used about the sick with infectious disease are to be cleansed. Such articles are difficult to disinfect unless special apparatus is at hand to facilitate the operation. Whenever such special means are

not procurable, the only safe and proper course to pursue would be to burn the articles in question.

Superheated steam or hot air has but a limited application in disinfection. It penetrates so slowly that the exposure of many fabrics to a degree of heat and for a length of time necessary to destroy the infectious material renders them much less durable, and may even change the colors of cotton and woollen fabrics. It is also very difficult to regulate the temperature when dry heat is employed as a disinfecting agent ; but used in connection with steam, however, dry heat is very useful, increasing the effectiveness of the latter, and as the temperature increases the period of exposure of the article in the disinfector is shortened.

Moist heat, or steam, is the most reliable and useful disinfectant we have. Unlike chemical disinfectants, it cannot be neutralized, while with care and proper treatment, the most delicate fabrics can be sterilized by means of it. All articles of clothing, bedding, carpets, curtains, towels, papers, letters, and a variety of fabrics can be thoroughly and quickly disinfected by steam, the period of exposure being regulated by the bulk or size of the article and permeability of the substance. Disinfection by steam is not applicable, however, to articles of clothing or bedding soiled by blood or pus, as the stain becomes fixed.\* Articles of leather and rubber also cannot be disinfected by steam.

Corrosive sublimate is of doubtful utility. With albumin, the salts of mercury form compounds which are coagulated or precipitated upon the surface of the substances to be disinfected, forming a veneer or coating, which prevents contact of the disinfectant with the infectious material. An excess of mercury salt dissolves the albuminate of mercury, which is of itself a disinfectant of considerable power. It is necessary to use a quantity of this material greatly in excess of that really required to disinfect a mass of infectious material, and even then there would be no certainty of complete and absolute disinfection. Its use should be limited to substances of a non-albuminous character. It should never be used about instruments or articles of a metallic nature, as it attacks metallic surfaces.

As a disinfectant for the wood-work, floor, walls, and furniture of the sick-room, for carriages, hacks, and vehicles used in transporting the sick with infectious disease, there is no better agent. It should be applied in solution (1 to 500 or 1 to 1000), using a scrubbing-brush or broom.

Crude carbolic acid is a very poor disinfectant; as the quality improves, the effectiveness of the agent increases. Mixing with an equal quantity of sulphuric acid also increases its power. It has quite a wide range of utility, and is generally applicable to disinfection of sputa, dejecta, and discharges. It is used in solution of from three to five per cent.

Chloride of lime depends upon the available chlorine present for its efficacy as a disinfecting agent. It is limited to cleansing cesspools, vaults, cellars, and places of like character.

Sulphur is another agent of doubtful utility, often overestimated. It is quite settled that the action of sulphur does not penetrate to the degree formerly supposed, the evidence tending to show that it acts upon the surface only. It has but a limited application in or about the sick-room.

Calcium hydroxide, in the form of milk of lime, is another disinfecting agent which is very useful among chemical agents. Its range of utility exceeds all other disinfectants; all micro-organisms are destroyed by it, whether applied to walls as whitewash or mixed with the infectious material. It is more generally applicable as milk of lime, which consists of recently-slaked lime mixed with four parts of water. In this form it can be used to disinfect excreta, discharges in sputa cups, and, if desired, can be applied to walls or used to disinfect the contents of cesspools and vaults. It always should be added to the point of marked alkaline reaction, the alkalinity determined by testing with litmus, the use of litmus being necessary on account of the varying quality of the lime due to age and many impurities in the lime. Unslaked lime should never be added to infectious material, as the action is so slow that the mass is not entirely disinfected, as the lime, slaked and neutralized, is not diffused throughout the mass until it has lost its power as a disinfectant.

#### VAGINAL HYSTERECTOMY WITHOUT CLAMPS OR LIGATURES.

"The assertion that vaginal hysterectomy may be so performed as to make the operation almost a minor one may strike the average surgeon as a strange one, and false; but it is a true statement," says LANPHEAR (*Kansas City Medical Index*, June, 1894). The method he considers the ideal one for small intramural fibroids, procidentia, and for early cancer of the cervix. For far-advanced epithelioma, causing symptoms sufficiently severe to de-

mand operative interference, it cannot be advised, nor can it be employed in tumors too large to be delivered through the vagina, nor in cases in which pyosalpinx is a complication. He bases these statements on four successful cases performed by himself, and thus endorses Pratt's conclusions:

1. The loss of blood is trifling, and as the vessels are not injured, they remain to repair the wounded parts, which they do with rapidity and completeness.

2. Diseased tissue is not disturbed, the uterus not being mutilated nor even wounded, the entire organ being removed intact.

3. If by accident a blood-vessel is cut, it is so perfectly in the field of operation that it can be readily secured by forceps and tied without injury to neighboring nerve-fibres.

4. There is no pinching of the sympathetic and spinal nerve-fibres by clamp or ligature, consequently there is no "shock" following operation.

5. When necessary the tubes and ovaries can be removed with no loss of blood and the peritoneal opening closed as perfectly as in coeliotomy, preventing hernia and leakage of discharges into the pelvis.

6. The operation seems almost devoid of shock or danger to the patient, practically converting a major operation into a minor one.

7. It possesses none of the bad features of vaginal hysterectomy by the clamp or ligatures,—viz., high death-rate, slow convalescence, and disturbances due to pressure.

8. There is scarcely any pain and very little soreness after the operation, the reaction and healing are rapid, the freshness and buoyancy of the patients are restored to them, and their natures, instead of being changed for the worse, are radically improved.

---

#### THE VALUE OF INOCULATIONS WITH SEPTIC OR TOXIC AGENTS IN THE TREATMENT OF MALIGNANT NEOPLASMS.

WYETH (*Journal of the American Medical Association*, June 30, 1894) presented a paper before the Forty-fifth Annual Meeting of the American Medical Association with the above title, in which he reaches the following conclusions:

1. Sarcoma may be cured by septic infection. The sepsis of erysipelas exercises the most powerful curative influence. Infection from the streptococcus pyogenes aureus will also cure sarcoma. The injection of the sterile products

of Fehleisen's coccus will also cause these neoplasms to disappear.

2. These agents act through the blood. Thus, erysipelas attacking a breaking-down sarcoma of the back, caused this to disappear simultaneously with a similar growth in another portion of the body of the same patient not locally infected. It is probably better to inoculate in the mass and get the local action of the inflammatory process when this is possible.

3. The lower the order of the structure of the sarcoma the less likelihood of a successful result. Thus, in tumors of a myxomatous character the prognosis is less favorable.

4. Epitheliomata may also be made to disappear or their growth may be retarded by septic infection.

5. Adenoid carcinomata are only slightly, if at all, susceptible to cure or retardation in growth by these agents.

#### AN EFFICACIOUS METHOD OF TREATING URETHRITIS.

LEWIS (*Kansas City Medical Index*, June, 1894), after calling attention to the anatomy of the urethra, states his belief that in ninety cases of a hundred of gonorrhœa it is necessary to treat the posterior urethra. In the treatment of this he employs, as a rule, the catheter and bulb for zinc sulphate irrigation and the deep urethral syringe for argentic nitrate injections. Solutions of graded strength of each of these remedies are used after fairly well prescribed rules.

After the acute symptoms have been subdued by time or judicious treatment,—that is, in the condition shown by most cases of chronic urethritis,—the method of treatment is inaugurated with the use of the milder of the two remedies,—an irrigation of zinc sulphate in the strength of one-twentieth per cent. The patient having first urinated, with glycerin lubrication a small, soft-rubber catheter (No. 12 French) is introduced into the urethra until its eye is placed proximal to the cut-off muscle,—i.e., within the posterior urethra; the bulb syringe, holding eight ounces of the solution, is applied to the distal end of the catheter, and three-fourths of its contents are injected into the posterior urethra, whose membrane is thus thoroughly bathed with the solution as it runs back into the bladder. The catheter is then withdrawn for an inch or two till its eye is external to the cut-off muscle, whereupon the remaining fourth is injected, running forward alongside the catheter, irrigating the anterior urethra. Thus, both the anterior and posterior

urethra have been thoroughly irrigated. The patient is told to stand up and pass out what has been injected into his bladder, and in so doing he accomplishes another irrigation of his entire urethra. Slight burning follows the irrigation. A day later the irrigation is repeated; two days after that another repetition, but with added strength, say one-eighth per cent.; two days later, one-fourth per cent.; and so on until two and one-half per cent. is reached, when usually the discharge at first present has disappeared and the high degree of tenderness is relieved. The second of the two series of treatments should then be instituted,—deep injections of silver nitrate.

After filling an Ultzmann syringe with a one-fourth-per-cent. solution of nitrate of silver, the catheter stem is lubricated with glycerin and introduced until its inner end has reached the deep urethra. The piston is now depressed at the same time that the syringe is being withdrawn, spreading the solution over the entire urethral tract. This awakens some transient reaction, such as desire to urinate. It is well, therefore, to have the patient sit down for a while till this passes off.

This treatment is repeated every other day for a time, with progressively increasing strength of solutions; usually it will not be found necessary to go above three per cent. With improvement the urethra tolerates the stronger solutions readily. With the disappearance of pus and shreds from the urine the patient may be considered cured. It will be found, however, that a few shreds will be apt to show in the first portion occasionally, long after it is justifiable to discontinue treatment. If the shreds are composed mainly of mucus, with only a few pus-corpuscles, they need not be regarded as indicating continuation of active measures.

If tuberculous infection be present the method is directly contraindicated.

#### CONTROL OF HEMORRHAGE IN SHOULDER AMPUTATIONS.

KEEN (*American Journal of the Medical Sciences*, June, 1894), in discussing this topic, first considers disarticulation of the shoulder. The control of hemorrhage in this operation is best accomplished by the use of Wyeth's pins. The patient is brought to the edge of the table with the shoulder projecting somewhat beyond the edge. The arm is held at a right angle to the body. Two sharp-pointed cylindrical pins eleven inches long and one-quarter of an inch in diameter near the head

(No. 20 French catheter scale) are used. A good deal of force is required to push the pins through the tissues, and the suggestion is made that the point be made triangular, like that of a trocar, to facilitate introduction. The anterior pin is introduced through the middle of the anterior axillary fold (tendon of the pectoralis major) at a point a little nearer to the body than what may be called the centre of the fold transversely. The point of emergence of the pin is of much greater importance than the point of insertion; this should be an inch within the tip of the acromion. The pin being pushed through, the point is protected by a sterilized cork. The second pin is now introduced at a corresponding point through the posterior axillary fold (tendon of latissimus dorsi), emerging again an inch within the tip of the acromion. Some little care is needed to avoid striking the spine of the scapula. The exact point of emergence is important, in order to avoid the precise objection which Treves adduces,—namely, that if the pin emerges near or at the tip of the acromion, the moment the head of the humerus is removed the tubing is apt to slip downward, compress the two flaps against each other, and thus hide the cavity formerly occupied by the head of the humerus.

The pins being placed in position, a piece of black rubber tubing half an inch in diameter is then wound tightly around the axilla and shoulder on the hither side of the pins. It is important that this tubing should be the pure black rubber, which is very elastic, and not the far less elastic white rubber tubing. The disarticulation having been effected, the main vessels and all visible smaller vessels are tied and the tubing quickly removed. All other spurting vessels are then seized with hæmostatic forceps. The pins are not removed by Keen until after seizing the vessels, so little have they been in his way. The punctures made by the pins heal quickly and are absolutely of no importance.

In amputation of the shoulder-joint, in cases where the axilla is involved so high that the pins cannot be employed, Keen advocates Delpech's method.

When it is necessary to remove the arm, the scapula, and the clavicle, the method advocated by Berger is endorsed. The steps of the operation are described as follows: "An oblique incision extending from the external third of the clavicle to an inch above the inferior border of the great pectoral muscle. We thus discover and can cut, near to its origin on the coracoid process of the scapula, the lesser pectoral. The index finger is then carried through

the cellular tissue along the serratus magnus muscle, then the subscapular muscle, and is used as a hook in order to draw outward the mass of vessels and nerves. The artery is always situated at the anterior part of the mass, is surrounded and, as it were, indicated by the two roots of the median nerve, and nothing is easier than to surround it with a ligature which will embrace nothing else. This process appears preferable in that it produces but little injury to the parts, that it leaves a certain space between the ligature and the trunk, and permits temporary compression of the subclavian artery above the clavicle on the first rib."

#### SURGERY OF THE SPINAL CORD.

THORBURN (*British Medical Journal*, June 23, 1894), in a series of lectures delivered on this subject, states that the mortality of laminectomy after injuries is about sixty-seven per cent., as against eighty per cent. for the untreated cases. The operations for tuberculosis give better results. Thus, of seventy cases performed by seven operators, there were but twelve deaths due to or hastened by operation, giving a percentage mortality of 17.1; therefore the writer holds that the dangers of the operation are not great, especially in view of the conditions which it is intended to relieve. The fatal issue is usually due to shock. In a collection of thirty-eight cases of penetrating wounds of the spinal cord, there were fifteen deaths, nine due to septic infection, usually taking the form of a rapidly-spreading meningitis. It is held that in case of suspected injuries of the cord, which are liable to be septic, the wound should be left open, thus allowing of the escape of such discharges as may form. The question of recovery of function after penetrating wounds is one of extreme importance. In twenty-one cases the opportunity for recovery of structure and of function was the best possible. There could have been no great separation of the cut surfaces; there was no septic infection. In spite of these most favorable conditions, complete recovery of function occurred in three cases only. Of the numerous cases with permanent symptoms, very few showed any amelioration of the earliest condition. The conclusion from this seems clear that in man we cannot hope for anatomical recovery; that vicarious conduction may allow of restoration of function to some extent, but that in the case of complete transverse lesions, in which vicarious conduction is manifestly impossible, no recovery whatever will take place. This conclusion by no means applies to nerve-

roots after they have left the structure of the cord. Indeed, we may confidently anticipate recovery of the nerve-roots when divided within the vertebral canal. In compound fractures, which are chiefly gunshot wounds, all splinters and foreign bodies should be removed. Fracture of the spinous process, when brought about by direct blow, when the bone is sunk below its normal level, would also call for operation.

In fractures of the laminae, operation is indicated if there are symptoms of pressure upon the cord. There is here no reason to anticipate a rebound of the bony fragment. There is also a reasonable probability that the medullary lesion is not a complete crush. Finally, the operation itself is the simplest. Of three recorded operations, two were completely successful.

In fracture dislocations of the bodies of the vertebrae, displacement is almost always forward and downward. In association with these lesions it is probably not very rare to meet with diastases,—that is to say, with dislocations in which the displaced bones have recoiled, so as to leave no permanent disturbance of the relations. Nevertheless, the cord may be very seriously injured. The fractures are usually oblique, from behind and above downward and forward. The distinction between a crush, followed by recoil of the bones in the proper position, or a similar injury associated with a temporary compression, is one which is extremely difficult to make. The asymmetry or deformity may sometimes aid in forming an opinion. In two instances there have been obtained excellent results in operation for hemorrhage into the spinal canal, in both cases the clot being removed by laminectomies. In one case this operation was not performed for three months after the injury, when there was removed a firm fibrous tissue, which had formed in the clot. There is one unusual lesion which can be recognized; this may be called gravitating hemorrhage, which makes its presence known by paralysis extending upward. Operation at the site of injury would be indicated in such a case. The author holds that, for all practical purposes, we have three varieties of injury which call for treatment,—namely, permanent pressure upon the cord, temporary crushing of the cord, and hemorrhage. The latter is so rare and so little likely to be diagnosed that we are almost justified in neglecting it. As regards the two former, it is clear that in cases of temporary compression—which constitute the majority—laminectomy is necessarily useless. The crush is over, the cord has already sustained its maximum of injury, and it lies in the best possible position for re-

covery, if such be possible. In cases of permanent compression, on the other hand, we may certainly restore the normal lumen of the vertebral canal, but we can hardly hope to do much, if any, good to our patient; in the first place, because, as we have already seen, the injured cord will not be capable of regeneration; and, in the second place, because the extreme mortality—or, at least, persistency of symptoms—in the cases of temporary compression is such that we can hardly hope for benefit in the more severe cases in which the compression has been permanent.

Finally, he concludes, in compound fractures, operate. In fractures of the spinous processes and laminae, with injury to the cord, we also operate. In simple fractures and dislocations of the bodies of the vertebrae, if there is a reasonable probability that the injury is due to hemorrhage, operation is advisable; but in all other cases, however, laminectomy is not an eminently valuable surgical procedure.

#### PREScriptions.

The following application is recommended in ichthyosis and chronic eczema:

R Papain,  $\text{gii}$ ;  
Acidi salicylici,  $\text{zi}$ ;  
Glycerini,  
Ol. ricini, of each,  $\text{ziv}$ . M.

Sig.—Apply, with friction, to the surface of the body.

Antipruritic oil:

R Acidi carbolici,  $\text{zi}$  to  $\text{gii}$ ;  
Liquor potass.,  $\text{zi}$ ;  
Ol. lini.,  $\text{zi}$ .

M. et adde ol. bergamot, q. s.

Sig.—Shake before using.

—*British Journal of Dermatology*, July, 1894.

#### RUPTURED INTESTINE FROM ACCIDENT; LAPAROTOMY; SUTURE OF GUT; RECOVERY.

THOMAS (*British Medical Journal*, June 23, 1894) was called to see a patient, aged fifty-five, who twenty-four hours before had received a blow upon the abdomen which had caused vomiting and persistent pain. On admission, the pulse was 80 and strong; the patient was able to walk. Operation was performed immediately, and an incision through the belly-wall evacuated upward of a pint of putrid serum; a thorough search showed a perforation of the ileum, from which liquid faecal matter was oozing. This rupture was closed by a double row of Lembert sutures. The abdominal cavity

was thoroughly irrigated with 1 to 100 carbolic lotion, and a drainage-tube inserted and the belly-wound closed. Recovery was uninterrupted.

#### PEAT WOOL IN SURGERY.

For many years there has been a gradually growing demand on the Continent for peat in a coarse powder for use as an absorbent and deodorant of excreta, for by its use the dry system of sewage removal, obtaining so largely abroad, was found to be deprived of the various and obvious objections thereto. The reason of its growth in favor for this purpose was found to be its power of absorbing liquids (nine times its own weight of water), of causing the liquids which it has absorbed to be resistant to putrefaction, and of fixing and preserving the ammoniacal products present in sewage. The two former of these properties soon attracted the attention of the surgical world abroad, a monograph being written on the subject ten years ago in Germany. BURGESS (*Lancet*, July 21, 1894) states that more recently the invention of processes for extracting the fibre from dust and *débris*, and the discovery of the fact that these fibres will form a wool of a firm, elastic nature, have given a great impetus to the use of peat in surgery. So great has been the favor this product has gained abroad that the French War Department has now definitely adopted it to replace the gauzes and wools which have been hitherto used in the military hospitals. Peat fibre, as now prepared for surgical purposes, is a fine, brown, glossy wool, with a faint aromatic smell. It feels a little rougher than fine absorbent wool, but makes a more comfortable dressing, as it is much more elastic. Microscopically, one would, of course, expect to find the more resistant portions of vegetable tissues in a dry and shrivelled condition. Various different observers have described different forms of cells in peat. One especially draws attention to cells provided with stomata, through which the fluids flow in and fill the empty cell cavity when the fibre is immersed. In the samples examined by the writer the microscopic structure was exceedingly simple. The fibres were macerated in a solution of potassium, teased out, and examined with a one-eighth-inch objective. It was found that they consisted almost entirely of very long and very narrow cells, with finely tapering ends. The fine peat fibres consisted of bundles of from fifty to one hundred of these cells, which were from one-fifth to one-fourth the diameter of fine cotton fibres. They were per-

fectly homogeneous and glassy; they had a minute cell cavity, which appeared as a fine dark line, with no trace whatever of stomata. Besides these, every here and there was a much broader cell, with transverse marking, resembling the peculiar vessels of plants, and there were a few polygonal vegetable cells adherent to these. The most striking points were the small size of the fibres, their great length, transparent, homogeneous structure, and regular grouping.

With regard to the reputed antiseptic qualities of peat, careful investigation has quite settled the fact that peat contains a substance which does definitely retard the development of micro-organisms. This substance or substances can be extracted by steeping the peat in water, and is of a faint acid reaction, but its exact composition has not been worked out. There is, however, some power of preventing putrefaction present in peat greater than is accounted for by the possession of this substance, and it is surmised that it is the fact of the absorbed fluids being actually taken into the empty cells, and held there out of contact with air, that to some extent accounts for this. No claim is made for its being in any sense a bactericide, but even the above retarding effect upon germ growth is a power not possessed by any other dressing material of itself. If a stronger antiseptic be needed, peat, described above, can be most effectively, on account of its arrangement of fibres, impregnated with perchloride of mercury or any other antiseptic.

LUCAS-CHAMPIONNIÈRE gives a graphic account of the comfort experienced in cases of extravasation of urine necessitating free incisions after dispensing with ordinary dressings and packing with peat wool. The same writer goes on to describe numerous major operations where, even with much oozing, one single peat dressing was kept on until the wound had united. In the writer's own experience, in one case of cellular erysipelas, involving the entire leg and obliging numerous long and deep incisions, peat wool was entirely employed and fully justified its reputation. To recent and clean wounds a layer of perchloride gauze was first applied and then a pad of peat wool, and in no case was more than one dressing needed. For padding splints nothing better can be imagined; one gets an elastic pad which has no tendency to felt and which does not get sour and ill smelling, however badly it is treated.

With regard to its disadvantages, there are two: first, a tendency for the finer fibres to break if handled much, by which a little dust

is produced, and for this reason it is not recommended as an immediate application to operation wounds. The other disadvantage is its brown color; but in actual practice neither of these forms any noticeable drawback to its usefulness.

#### *MALIGNANT INDIAN SYPHILIS TREATED WITH THYROID EXTRACT.*

MENZIES (*British Medical Journal*, July 7, 1894) reports four cases of this disease in which thyroid extract was used with most gratifying results. The patients were all invalids, lying in the military hospital, having been sent down from their respective stations for change to England. They were all in a very weak, sickly state, the disease being complicated by malarial fever, bowel complaints, etc. All mercurial and alterative treatment was suspended for the time, in order to watch the effect of the remedy.

No recurrence of the eruption took place: Old cicatrices took on a healthy action and the pigmentation in a great degree disappeared. He particularly draws attention to the following considerations: 1. The exceptional virulence of the poison. 2. The undeniable value of thyroid extract given alone, without any mercurial preparations. 3. The hygroscopic and absorbent properties of the powdered extract. He found it useful for insufflation and dusting purposes. "Tabloids" are very susceptible to moisture. Three other cases came under his notice: (a) rupial ulcers of face and arms; (b) ozæna, with ulceration of nasal passages; (c) hereditary syphilitic patient with a broken-down gumma of calf. These men also decidedly progressed under the new treatment. He regards the remedy as a powerful skin tonic and adjuvant to the mercurial and alterative treatment of syphilis.

#### *RECURRENT APPENDICITIS.*

MAYO ROBSON (*Lancet*, June 30, 1894) reports eight cases of recurrent appendicitis in detail, and as a result expresses the following beliefs:

In the cases reported—characteristic ones, where the operation was performed between the attacks—there are three courses which may be pursued: 1. Non-operative, trusting to rest and diet, with opium, if required, in order to bring about resolution, in the hope that the existing attack may be the last. 2. Operation on the second or third day of a seizure, as advised by American surgeons, who discourage the removal of the appendix between the

attacks, on the chance that there may be no recurrence. 3. Operation in the quiescent period between the attacks, (a) because the patient is likely to be in the best possible condition; (b) because there is less likelihood of there being an extensive collection of inflammatory products in or in the neighborhood of the appendix, and therefore there will be less danger of soiling the general peritoneal cavity and less fear of peritonitis; (c) an operation in the quiescent period seldom requires drainage, and therefore the wound can be made secure, and there will be less likelihood of hernia following operation; and (d) the appendix can be dealt with in a more satisfactory manner than when it is acutely inflamed and hidden by greatly distended intestines. In deciding on the line of treatment, whether medical or surgical, the patient should have matters fully explained to him, the dangers of recurring attacks, with the sufferings and inconveniences, being balanced against the risk of operative interference and the results gained by operation; therefore, in all these cases Robson urges the co-operation of physician and surgeon, so that, if possible, the opinion given may be free from bias. Can these several risks be estimated? Fitz gives the mortality of perityphlitis medically treated as eleven per cent.; this is probably too high for attacks of recurrent appendicitis, but who is to say that in any case the next seizure may not end in perforation and death? What are the inconveniences? In all the cases related, incapacity for the ordinary pursuits of life and practically invalidism were marked features. What is the likelihood of recurrence? In the cases related there seemed to be every probability of the recurrences being repeated indefinitely, and it is probable that if any case suffers from two or three attacks, there is a strong probability of many more attacks until some complication supervenes.

What are the risks of operation in the quiescent period? Here we stand on more certain ground, for published statistics prove the dangers to be very slight in the hands of those accustomed to such operations,—not more than two or three per cent. And, lastly, What are the results which may be looked forward to after recovery from operation? In such cases as have been reported, and in the writer's now mentioned, the patients have been apparently completely cured.

Although the author does not agree with those surgeons who argue that every case of recurrent appendicitis should be operated on, he believes that in recurrent appendicitis operation should be resorted to as soon as it be-

comes evident that there is a probability of the attack being repeated, especially as the operation is one that can be undertaken in the quiescent period with every prospect of immediate and ultimate success.

#### THE USE OF ACETANILIDE IN SURGERY.

WOODS (*Journal of the American Medical Association*, July 21, 1894) has used acetanilide in twenty cases of operative wound and laceration. He finds it an admirable and curative application to internal hemorrhoids, and a satisfactory dressing in the form of a suppository after their removal by the Paquelin cautery. He recommends it as an injection in gonorrhoea, using,—

R Acetanilide, ʒi;  
Alcohol, ʒss;  
Aque, ad ʒviii.

Salol is administered along with this. The same injection may be used for the treatment of sinuses. In one case physiological symptoms of absorption of the drug became manifest, an unknown quantity of the medicament having been dusted over an extensive scald.

The advantages claimed for acetanilide are that it is cleanly, odorless, antiseptic, desiccant, hæmostatic, stimulant, alterative, non-toxic practically, lasting in its effects if intermitted, does not crust, is easily removed, and that it acts in these ways when perfect cleansing of a wound is impracticable, while it is a perfect substitute for iodoform at an insignificant cost, and is not injured or altered by moisture, as it may be saturated with water and, being drained and dried, is found to be unaltered.

#### TREATMENT OF STONE IMPACTED IN THE URETER.

Under this title, COTTRELL (*Lancet*, June 30, 1894) lays down the following treatment: It is very important in cases of renal colic to find out whether the stone has passed into the bladder or whether it has been arrested during its course. It has so frequently happened that an impacted stone becomes more or less quiescent, the condition causing atrophy of the corresponding kidney, and this condition has not been known or suspected until mischief on the opposite side has led to suppression of urine. Where, therefore, there is a history of severe renal colic of an intermittent character, combined with tenderness at one spot, the whole symptoms abating after a time without any evidence of a stone being passed

down into the bladder, impaction must be most strongly suspected. If combined with symptoms pointing to the formation of a hydronephrosis, the diagnosis becomes a certainty.

This is one of that class of cases where the ureter should be explored and the stone, if found, extracted. The patient should be urged to submit to this treatment, and the consequences if he neglects to notice the danger signal should be clearly put before him. In another class of cases we are called upon to operate for hydronephrosis or for pyonephrosis, resulting from impacted stone. If there is reason to suspect that a fair amount of working kidney has escaped the disorganization, it may be worth while to search for and remove the impacted stone before proceeding to more radical measures.

If we are called upon to operate upon a case where suppression of urine has come on, the treatment will be best discussed under two heads: (1) where the symptoms of uræmic poisoning are not well marked; (2) where the uræmia is well pronounced. In cases coming under the first heading, we must be certain, if possible, which is the side affected with calculus, and the history of the case will help to guide us in this matter. Having decided upon which side the impaction has probably occurred, the ureter should be thoroughly explored, and if a stone is found it should be removed. If no stone is found, it will be good surgery to cut down upon the kidney and put a drainage-tube in the pelvis, which will probably prevent the patient dying from uræmia. Under the second heading, where uræmia has supervened and its symptoms are well marked, it is certainly not good treatment to search for an impacted calculus. In a case of this kind we should be content to make an opening into the kidney and drain off the urine. It might happen that, owing to want of a careful history of the case and in the absence of subjective symptoms, an atrophied kidney is opened, or that organ may be absent on the side operated upon. Should the surgeon come across either of these conditions, the best thing to be done is to turn the patient over at once and to operate upon the other side.

If the drainage of the kidney relieves the uræmia, a search should be made for the stone when the dangerous symptoms have subsided.

When a stone is impacted in the upper part of the ureter, the symptoms are so like those of stone in the kidney that the two conditions have always been confounded, and the diagnosis of impacted stone has only been made after a nephrotomy has been performed. If a pa-

tient has symptoms of stone in the kidney, and a very careful exploration fails to reveal the calculus, the upper part of the ureter should be explored, the nephrotomy wound being somewhat enlarged, if necessary, for this purpose. If not found, a soft bougie might be passed down the tube and an endeavor made to locate the calculus, and if this is successful the stone can be easily removed.

Mr. Godlee reports a case in which he successfully pushed the stone on to the bladder by an œsophageal bougie. The author condemns this treatment as a routine practice, pointing out that there is no evidence at all to point out the size of the stone, and the symptoms may be quite as severe where the calculus is small as where it is too large to be pushed through the mouth of the ureter. Further, if ulceration of the ureteral wall has taken place from pressure, it would be very easy to push the stone and bougie out of, instead of down, the ureter. The middle three-fifths of the ureter can be very conveniently exposed and explored by an operation similar to that which is laid down in the text-books for ligature of the common iliac artery. As is well known, when the peritoneum is stripped up it always carries the ureter forward with it, and advantage can be taken of this fact. Having found the ureter, it may be explored between the finger and thumb nearly to its lower end. Should a calculus be found low down and not in a position where extraction is easy, it is desirable to work it up to opposite the wound with the thumb and finger, and then extract it. The lower end of the ureter may be explored in the female through the vagina and in the male through the rectum. The removal of stones from the lower end may be accomplished very easily in the female by cutting down upon them through the roof of the vagina. Where they project into the bladder, Mr. Morris advises that the ureteral opening of the bladder should be enlarged by cutting and the stone extracted by forceps. This operation might be effective where but one stone existed, but where there are several, as is generally the case, the manipulations necessary in removing the stones by forceps might possibly open the peritoneum, the only case in which this method was employed having terminated fatally because of this accident. Finally, in operation for impacted stone at the lower end of the ureter in the male, the writer advocates a perineal operation, dissecting down between the urethra and the rectum until the base of the bladder is exposed. Advantage may be taken of the thickness and of the expansile property possessed by

the wall of the ureter. If the calculus is thoroughly squeezed between the thumb and forefinger, the wall of the ureter being stretched tightly over it, a longitudinal incision will, after the removal of the stone, so contract that in many cases its site cannot be afterwards discovered, except by a very careful search. The ureter should not be sutured.

#### PUNCTURED WOUNDS OF THE LIVER.

Under the above heading, R. ROMME (*La Tribune Médicale*, July 5, 1894) reviews this class of injuries, especially referring to the cause of President Carnot's death.

In the five hundred and forty-three cases of traumatic diseases of the liver collected by Edler, sixty-five were produced by cutting or pointed instruments. Of this number, twenty-three recovered and forty-two died. The cause of death in thirteen cases was from hemorrhage and in twelve from peritonitis. Shock was present in a great majority of cases. Pain was not so common a symptom, nor was jaundice a constant sequel. Bilious vomiting, however, was very frequent, as were also respiratory troubles, as cough and dyspnoea.

The principal symptoms—traumatic shock with collapse, local and radiating pains, nausea, vomiting, and respiratory disturbances—were all present in the case of M. Carnot. We quote the report given at the time:

"At the moment of the accident the President carried his hand to his breast, saying, 'I am wounded,' and with that he lost consciousness. He was laid down in the carriage, with the head thrown back. His face was very pale, and his eyelids, half closed, gave the impression of impending death. During the time required to transfer him to the préfecture he suffered from nausea two or three times, but did not vomit. Under the first incisions of the operation he regained consciousness, responding distinctly to the questions concerning his sufferings, the face remaining always pale and his strength gradually sinking. Later he complained of dyspnoea, followed by some convulsive movements, and soon afterwards died. As internal hemorrhage was suspected, ice compresses were applied to the abdomen while preparations were being made for the operation. Upon the arrival of instruments, without administering an anæsthetic, an incision twelve to fourteen centimetres long was made in the abdominal walls, allowing the escape of considerable blood. The lips of the incision were picked up by hæmostats, allowing better exploration. A puncture of the liver to the depth of two to three centimetres was

discovered; this was enlarged and packed with gauze. Before the operation could be concluded, however, the President suddenly experienced great agony, and with a convulsive movement, which caused extrusion of the intestines through the parietal incision, passed away. The autopsy showed a wound of the left lobe of the liver twelve to thirteen centimetres deep, opening the portal vein in two places, and causing death from intraperitoneal hemorrhage."

From the experience gained in this case, the author would recommend early exploratory laparotomy in penetrating injuries of the liver.

#### HALLUX RIGIDUS.

COLLIER (*Lancet*, June 30, 1894) gives some valuable points on the stiff and painful condition of the metatarso-phalangeal joint of the great toe, usually consequent on and associated with flat-foot, and, like flat-foot, not necessarily confined to one foot, but more often, sooner or later, affecting the same joint of the opposite foot. The victims of this disorder are usually young persons at or about puberty. Males would appear to be more often affected than females, doubtless due to the fact that young males are more frequently employed in arduous work, necessitating more standing and the carrying of heavier weights than females. This affection is not necessarily associated with any permanent constitutional ailment or tendency, unless it be a want of vascular and muscular tone and some impairment of nutrition. The affected foot presents a peculiar and characteristic appearance. In the first place, it is an abnormally long foot for the size of its owner. Next, the foot is nearly always cold, damp, and more or less blue, the tone of its vessels, as well as its nutrition, being apparently impaired. The distortion of the foot is characteristic and peculiar, and is due to the fact that any pressure between the head of the metatarsal bone and the sesamoid bones on the tendons of the short flexor cannot be tolerated. The metatarsal bone is flexed on the tarsus and is adducted to the midline from its fellows. With this the proximal phalanx is slightly flexed. The head of the metatarsal bone appears through the skin to be enlarged, and there is found sometimes some lipping of the cartilage of this bone at its under and lower aspect, in the neighborhood of the sesamoid cartilages. In early cases pain is not usually complained of until the end of the day, and then mostly after long standing or much walking; but as the disease progresses, the pain is

continuous, except when the patient is not standing and at night. The joint is never red, painful, or tender to the touch, except on manipulation, and gives no indication of containing fluid or of being the seat of acute disease. Flexion of the joint is generally readily permitted, but any attempt at an extension elicits opposition and evidence of acute pain on the part of the patient.

The author has diagnosed, treated, and subsequently operated on nine cases,—two females and seven males,—and in all but two the subjects were young adults between sixteen and twenty years of age. In all the disease was associated with flat-foot, cold feet, and impaired nutrition. After a preliminary trial of tonics, frictions, and appropriate boots, all were operated on, and the head of the metatarsal bone removed. The joints healed by first intention, and a movable and useful joint resulted.

#### ILEO-COLOSTOMY, AFTER SENN'S METHOD, IN WHICH PLATES WERE MADE FROM THE TURNIP-CABBAGE.

BOROCZ (*Centralblatt für Chirurgie*, July 7, 1894) successfully performed ileo-colostomy by using fresh cabbage-turnip plates.

A young man, aged nineteen, presented himself with a tumor in the cæcal region the size of a hen's egg, and from the history chronic inflammation of the cæcum with adhesive peritonitis was diagnosed. As the enlargement was causing obstructive symptoms and impairing the general health, its removal was attempted. Upon examination, the enlargement was found in the cæcum, into which the ileum had become invaginated and grown fast. Two clamps were applied to the intestines; the ileum and then the colon were severed, invaginated, and closed by sutures. The tumor was then attacked, but so many adhesions presented that it was finally left *in situ*, and the union of the two intestinal ends by lateral anastomosis was proceeded with. Two plates of the cabbage-turnip (Kohlrüben) were used, resembling Senn's decalcified bone-plates, each having a central opening of three centimetres; these plates should be freshly prepared.

The threaded plates were applied as Senn has instructed, with the addition of the Kürchner suture on the lower side previous to fastening the plates, whereby the serous membranes were united at this point. After the union of the four principal ligatures, the operation was completed by continuing the Kürchner suture on the remaining side and two ends. The opera-

tion point was then covered by the great omentum and the peritoneal cavity cleansed with sterile gauze.

At the end of the operation, which lasted two hours, the patient was in a state of collapse and his pulse was 120 per minute; but prompt treatment was given, and his improvement was prompt. On the third day the plates passed. Eleven months after operation the patient was in normal condition, without any trace of the enlarged cæcum to be found.

#### A CASE OF CUT-THROAT.

HISLOP (*Lancet*, June 30, 1894) reports an interesting case, as follows: On April 13 he was called into the country to see a man, seventy-four years of age, who had cut his throat. On reaching the patient, he found him sitting, supported by two people, on a night-chair, with a huge, gaping, and slightly lacerated wound of the neck, extending to within half an inch of the carotids on either side. The trachea was all but completely severed, the band that was left being certainly not more than a quarter of an inch wide. The man had evidently lost a great deal of blood; he was pulseless and in a state of collapse. After tying four arteries, from which the blood was still coming freely, Hislop brought the ends of the trachea together with four strong silk sutures, washed the big cavity of the wound out with cold spring water, and brought the surfaces together with ten interrupted silk sutures. The wound was dressed with a thick pad of dry lint and surrounded with cotton wool. By this time the man had completely recovered consciousness, and was able to speak freely and without pain. Recovery followed uninterruptedly and was completed May 28.

#### GLYCERIN INJECTIONS AS AN OXYTOCIC.

PELZER (*Centralbl. f. Gynäk.*, No. 26, 1894) read a communication on this subject at a recent meeting of the Cologne Obstetrical Society. He had collected twenty-eight cases, including nineteen in his own experience. Glycerin was used eighteen times for induction of premature labor; in fifteen of these cases the pelvis was narrowed, in two there was Bright's disease, and in one placenta prævia. To stimulate uterine action at term, glycerin was injected in seven cases of simple atony, in two of placenta prævia, and in one for some other complication. The pains came on after an average interval of two hours following the

injection. Eight to ten hours elapsed before complete dilatation of the os, or a longer space of time in cases of contracted pelvis. Two of the mothers died, both from severe eclampsia; the foetus was putrid in both cases. One child required craniotomy on account of its great size. Three children died from placenta prævia and strangulation by the funis. One, hardly thirty-two weeks old, died a quarter of an hour after birth. Only in one case could the violence of the pains be a possible cause of the death of the child. The glycerin had done its duty. Pelzer, however, deprecates injudicious zeal in this method; thirty to fifty cubic centimetres, not one hundred cubic centimetres, are sufficient for injection. The method is not suitable for cases of eclampsia and placenta prævia, except the lateral variety, where the placenta can be avoided.

GEUER (*ibid.*) read notes of three cases of induction of premature labor by injection of glycerin, in all of which both mother and child were saved. The first two mothers were over thirty-two, with contracted pelvis; craniotomy had been performed in previous labors. The third case was an instance of bad eclampsia; 40 grammes of glycerin were injected, the os being at the time uncontracted; there was oedema, with much albuminuria. Forty hours later a healthy living child was born.—*British Medical Journal*, July 21, 1894.

#### APPENDICITIS OBLITERANS.

SENN (*Journal of the American Medical Association*, quoted by the *Canadian Practitioner*, July, 1894) concludes his paper on this subject as follows:

1. Appendicitis obliterans is a comparatively frequent form of relapsing inflammation of the appendix vermiformis.

2. It is characterized by progressive obliteration of the lumen of the appendix, by the gradual disappearance of the epithelial lining and glandular tissue, and the production of granulation tissue from the submucous connective tissue, which, by transformation into connective tissue and cicatricial contraction, starves out remnants of glandular tissue, and finally results in obliteration.

3. The obliterating process manifests a progressive tendency, and may finally result in a complete destruction of all glandular tissue and obliteration of the entire lumen.

4. The incipient pathologic changes occur either in the mucous membrane of the appendix, in the form of superficial ulceration, or as

an interstitial process following lymphatic infection.

5. The most constant symptoms which attend this form of appendicitis are relapsing acute exacerbations of short duration, moderate or no appreciable swelling at the seat of disease, and persistence of soreness and tenderness in the region of the appendix during the intermissions.

6. The process of obliteration may begin at the distal or proximal end, or at any place between, or it may commence simultaneously, or in succession at different points.

7. Obliteration on the proximal side gives rise to retention of septic material, which finds an outlet through the lymphatics, giving rise to non-suppurative lymphangitis and lymphadenitis.

8. Circumscribed plastic peritonitis is an almost constant concomitant of appendicitis obliterans, and hastens the process of obliteration.

9. Complete obliteration of the lumen of the appendix results in a spontaneous and permanent cure.

10. In view of the prolonged suffering incident to a spontaneous cure by progressive obliteration and the possible dangers attending it, a radical operation is indicated, and should be resorted to as soon as a positive diagnosis can be made.

#### RESORBINE: A NEW OINTMENT BASE.

LEDERMANN (*British Journal of Dermatology*, July, 1894) reported to the Berlin Dermatological Society a base which is capable of traversing the skin after moderate rubbing in, and which leaves a slight covering layer. It is made with some difficulty after a patented method by emulsifying pure almond oil and a little wax with water and a small percentage of other innocent but necessary vehicles. Resorbine can be mixed with all vegetable and animal fats. It is especially advantageous to add a little lanolin. Its use is indicated in all the hyper- and parakeratoses, as ichthyosis and pityriasis, and in scleroderma, in artificial dermatitis, ulcerations, rhagades, scabies. It combines well with Neapolitan ointment. The price is about the same as that of lanolin.

#### STATICAL ELECTRICITY IN ECZEMA.

DOUMER (*Arch. d'Électricité Médicale*, May, 1894) reports favorable results in eczema from the employment of the electric soufflé. Of fifty cases, forty-eight were completely and rapidly cured. The cases enumerated include both

acute and chronic eczema, and the patients were of various ages. He advises the use of a machine capable of giving sparks three inches long, and an electrode with points for the breeze or brush discharge. Either the negative or the positive pole can be used, no difference in their action upon the complaint having been noticed.—*British Medical Journal*, July 14, 1894.

#### APPLICATION FOR PSORIASIS.

Chrysarobin is dissolved in chloroform (1 to 7), and to it an equal amount or less of linseed oil is added and thoroughly stirred with a hog's bristle shaving-brush. With this mixture the diseased area is well scrubbed.—*British Journal of Dermatology*, July, 1894.

#### DOUBLE SEPTIC ORCHITIS COMPLICATED BY PERITONITIS.

HORNUS (*Archiv. de Pharm. de Mil.*, July, 1894) records a case of double septic orchitis complicated by peritonitis and terminating fatally. The patient had no preceding venereal disease. The onset was sudden. After a few days symptoms of peritonitis set in. The patient perished. On incision into the testicles pus was found, the glandular substance of the organs having been completely destroyed. This pus had extended along the cord through the inguinal canal and into the iliac fossa, where several drachms were found. The inflammation is supposed to have been due to mumps. Early free incision probably would have prevented extension of the inflammation to the peritoneal cavity.

#### TYPHOID FEVER COMPLICATED BY GANGRENE IN BOTH LEGS.

DURAND (*Archiv. de Pharm. de Mil.*, July, 1894) publishes a case of typhoid fever complicated by gangrene in both legs. At the third week of his disease the patient complained of a tickling sensation and of coldness in both feet. On the following day, in addition to these symptoms, he had incontinence of urine, and had a constant desire to pass his water. Examination then showed discoloration of the feet, total loss of sensation, and marked lowering of temperature. The symptoms of local gangrene steadily progressed; this took the dry form. Some disseminated gangrenous spots also appeared on both legs in the region of the sacrum and the right trochanter. The gangrenous process slowly extended, the patient

at the same time steadily losing ground. Four months later both legs were amputated at about the upper third. The patient recovered.

### THIOSINAMIN INJECTIONS IN LUPUS.

DR. W. VAN HOORN (*Monatshefte für Praktische Dermatologie*, June, 1894) has used thiosinamin in a few cases of lupus, and reports the following results:

After the injection of the drug there was swelling of the skin, often very considerable and rapid; twenty-four hours later a rich desquamation followed; while during reaction there was a sense of heat and stretching of the affected point.

When treatment was regularly followed there was almost always improvement; ulcers healed over, swellings were reduced level with the surface. One patient, with wide-spread "lupus tumidus" and "verrucosus" of the left arm and back of the hand, showed marked improvement after fourteen days. Yet in three other cases in which the treatment was followed he saw no improvement until he changed to salicylic plaster.

In two cases, handled unsuccessfully with tuberculin, thiosinamin was tried for fifteen months, an injection being given every two to three weeks.

At first two cubic centimetres (.2 gramme of thiosinamin) of a fifteen-per-cent. alcoholic solution (Hebra), and later the same dose of a ten-per-cent. glycerin solution (Duclaux) was used, the latter causing less pain upon injection. Throughout the entire fifteen months the injections were well borne and improvement noted, but at the expiration of this time the patients complained of loss of appetite, numbness of the head, and a sense of weakness and fatigue in the whole body, but especially the limbs.

These complaints increasing after each injection and lessening upon cessation of treatment, the treatment was discontinued, and again improvement was noted for another three months. As a result of his experience, he thinks that in most cases of lupus it is not wise to commence with the thiosinamin treatment, but to hold it in reserve until after the local treatment has failed.

### INGESTION OF THE THYROID GLAND OF THE SHEEP IN MYXEDEMA.

At a meeting of the Hospital Medical Society, Paris, M. P. MORIE (*Revue de Thérapeutique Médico-Chirurgicale*, June 15, 1894) re-

ported a case of myxœdema cured by the ingestion of the thyroid gland of the sheep.

The woman, aged forty-two years, had been unsuccessfully treated by injections of the juice of the thyroid gland. Last October she commenced eating daily two lobes of the thyroid body of the sheep, and her condition is now much improved, perhaps is cured, but he considers it necessary to continue the treatment indefinitely.

### A NEW METHOD OF REDUCING BACKWARD DISPLACEMENTS OF THE UTERUS.

JULES BATNAUD (*Revue Médico-Chirurgicale des Maladies des Femmes*, May, 1894), reporting the communication of Rapin at the Rome Congress, says that many cases of backward displacement of the uterus, in which this organ is supposed to be adherent to the surrounding viscera, are, as a matter of fact, simply held in Douglas's pouch by a combination of atmospheric pressure, the intestines, and the two layers of the sacro-uterine ligament, which imprison it laterally. To dislodge the uterus from this incarcerated position, Rapin has proposed this procedure:

The first two times insert the sound and rotate in the usual way. If the position remains unchanged, the third time, instead of lowering the handle of the sound, press upon the sound from behind forward and from below upward, moving the uterus as with a lever; by so doing one presses upon the entire anterior face of the uterine cavity, not only with the point, but with the entire part of the sound within the uterus; then we raise and draw the uterus forward and upward without endeavoring at first to replace it.

By this manoeuvre we dislodge the fundus from the rectum, opening the cul-de-sac, and the intestines, pressed down by the atmospheric pressure, fall into the place formerly occupied by the fundus, thus aiding in the forward movement of the organ.

At the moment the intestines assume their new position one feels that the resistance is overcome, and if now the handle of the sound is lowered, the replacement is completed without the aid of force or the provoking of pain. The sound is withdrawn, while, with the index finger still in the vagina, the neck of the uterus is pushed backward and the fundus comes forward into position. When there is resistance to the upward and forward traction, instead of the continuous pressure, a to-and-fro or a sawing movement causing the uterus to advance in a zigzag manner is often of advantage.

In all these manipulations the sound is governed by one hand, while the index finger of the other is placed within the vagina, palpating the cul-de-sac and controlling the sound within the uterus.

To maintain the uterus in position a pessary is used that fits partly in the vagina and partly within the uterine cavity.

#### REMOVAL OF LARGE FIBRO-MYOMAS OF THE UTERUS BY MEANS OF A PERI-NEO-VAGINO-RECTAL INCISION.

At the Rome Congress, M. PÉAN (*Revue Médico-Chirurgicale des Maladies des Femmes*, May 25, 1894), under the above title, proposed a method for the removal of large interstitial fibroids of the uterus, attacking the tumor from below.

To obtain access to the tumor two large toothed forceps are used; the blades of the instruments being placed respectively in the vagina and rectum and forcibly closed, render the further steps of the proceeding bloodless. The perineum is divided in the median line, including the vaginal and rectal mucous membrane, up as far as the peritoneum, exposing the tumor. The two large hæmostats, being given to an assistant, are used as retractors, and the tumor is seized with toothed forceps and removed piecemeal, endeavoring to preserve all the uterine structure possible.

Bleeding from the tumor cavity is controlled with hæmostats, which are removed in a few hours, while the cavity is packed with iodoform or some suitably-prepared sponge, and a large drainage-tube is also inserted. After two or three days the sponges are removed and the cavity is cleansed by antiseptics passed through the drainage-tube.

The operation is concluded by sewing the two mucous surfaces of the vagina and rectum together with catgut, the intermediate structures being united; the operation is thus hastily and easily executed.

LONDON.

(From our Special Correspondent.)

*The Evelina Hospital for Sick Children.*—A visitor to London might very well spend a part of his time in visiting the various hospitals. In former letters I have attempted to give some idea of the working of St. Bartholomew's Hospital, the most flourishing of our larger institu-

tions, with the view of rendering it more easy for an intending visitor to see the things most worthy of notice with the greatest economy of time. In the present communication I hope to give a similar idea of one of the minor hospitals,—the Evelina, situated in Southwark, and devoted entirely to the treatment of the diseases of children.

Instituted about four and twenty years ago, under the immediate care of Baron Ferdinand Rothschild, the hospital has enjoyed perhaps exceptional advantages. Under these auspices it has grown from an institution of only twenty-four beds to one capable of accommodating sixty-six in-patients; and its increase is not going to stop here, for arrangements are already on foot, and will very shortly be carried into effect, by which the number of beds will be increased to a hundred. The accompanying plan, kindly furnished to me by Dr. Soltau Fenwick, one of the honorary physicians, will give a very good idea of the present arrangement of the building and also of the proposed alterations and enlargements. It is also to Dr. Fenwick that I owe most of the information which I am here enabled to place before your readers.

*As to the Actual Working of the Hospital.*—This is in the hands of two resident medical officers, two physicians to in-patients, two physicians to out-patients, and similarly two in- and two out-patient surgeons. The wards are practically fed from the out-patient department, and during the past year six hundred and twenty-seven children were admitted as in-patients, each making an average stay of thirty days. All diseases other than those of an infectious nature are eligible for treatment. The only infectious disorder in favor of which an exception is made is whooping-cough. The out-patient medical staff attend on four days and the surgeons on two days in the week. Each day an average of about twenty new cases is seen in this department, so that in the course of the year something like two thousand new cases come to each member of the staff. Add to this number an average of a hundred "old" patients daily, and it will be seen that the field for clinical observation is by no means a limited one.

*The Surgical Side.*—The surgeons are well provided for, and there is a good deal of operative work which falls to their share. Most of the minor operations are performed in the out-patient department, many of them under chloroform. The rest, comprising those of gravity or of a tedious nature, are performed in the excellent operating-theatre, which is complete

with every modern appliance. It will be found that in this, as in most other children's hospitals, chloroform is preferred by the anæsthetist, and has always been administered with perfect safety. If asked what are the conditions which most frequently come for operative treatment, I should say that necrosis of the various long bones and empyemata are far the most numerous; but in a poor neighborhood like that in the heart of which the hospital is situated, accidents are often occurring, and these naturally fall to the lot of the surgeons.

*The Medical Side.*—As a transition from the surgical to the medical work, I may draw attention to the empyemata, which come generally under the care of both physicians and surgeons. In this condition experience shows that considerable time and risk are saved by resorting as early as possible to active surgical measures. If the physical signs point to an effusion of a purulent nature,—high temperature, embarrassed breathing, displacement of thoracic viscera, dulness on percussion, alteration of the pleximetric curve, etc.,—an exploratory puncture is at once made by means of a small syringe or aspirator needle, and if the diagnosis be confirmed, free incision and drainage are carried out without further delay. As is well known, the prognosis in children is particularly favorable and death hardly ever occurs.

At this season of the year the most common ailment in the medical department is diarrhoea. Dr. Fenwick tells me that his experience leads him to rely chiefly upon antiseptics in such conditions. His favorite remedy is benzo-naphthol, which is given in grain doses thrice daily, even to very young children. It will be remembered that benzo-naphthol is a benzoate of  $\beta$ -naphthol, and that it is said to break up in the intestine into its constituents, both of which have an antiseptic action. Another remedy much used in this condition is carbolic acid, which is given in minim doses, either as a mixture or in the form of perle. Some of the physicians prefer creolin, giving it in drop doses on sugar, and in many cases this treatment is highly successful. Its nauseous odor and taste, however, prevent its finding favor with children. Lastly, creosote is used by some, but this is open to the same objections, and to a greater degree, as those already referred to in regard to creolin.

*Chorea* is another affection frequently met with in the out-patient department. The treatment of this affection hardly presents peculiarities. The little patients rapidly improve on large doses of belladonna or liquor arsenicalis. It is well known what large quantities of these

drugs choreic children will tolerate without difficulty.

*Whooping-cough* comes so often under treatment that it has been deemed desirable to devote a whole ward to the treatment of this affection. The most successful of all drugs at present in vogue is bromoform. It is given in doses of from 1 to 5 minims, either suspended in syrup or in a mixture, the taste being concealed by means of paregoric or some other flavoring ingredient. The drug does not appear to alter the duration of the affection, but is most useful in checking the paroxysms of cough and vomiting. I do not know whether it is a matter of common observation in other institutions, but I am given to understand that quite a large proportion of the serious cases of whooping-cough admitted at the Evelina develop military tuberculosis after admission.

Another ailment frequently met with in all children's hospitals—nocturnal incontinence—is generally treated by the application of the faradic current, used as strong as the patient can bear it. One pole is applied to some neutral point, such as the nape of the neck, and the other is applied to the perineum, the latter electrode being more or less cone-shaped, and provided with a movable covering of either chamois leather or, better, of amadou. With this arrangement a fresh covering can be used for each patient. Improvement is generally very rapid, and the trouble often ceases after a few applications of the current. Should it relapse, a renewal of the treatment is attended with equal success. Treatment by such means is found to be far more successful than by any of the drugs, such as belladonna, which were formerly employed, but which, if used at all, are given solely as adjuncts to the electrical treatment.

To complete this account of the Evelina Hospital, I would mention that there is a very efficiently equipped dispensing department, at which the patients, after receiving their prescriptions from the physicians, have their medicines dispensed to them, each patient contributing the nominal sum of a penny, which, presumably, covers the cost of bottle, cork, etc.

I am informed that medical men, of whatever nationality, are at all times cordially welcomed to follow the practice either of the out- or in-patient department, and as patients are expected to attend at 9 A.M., a very considerable amount of clinical material can be seen before mid-day, so that a morning spent in the institution cannot fail to be profitable to all who avail themselves of this invitation.

At the recent meeting of the British Medical

Association, among other papers, was one upon "The Diagnosis of the Three Chief Forms of Contagious Ophthalmia,—namely, the Catarrhal, the Purulent, and the Granular Varieties," read before the Section of Ophthalmology by Henry Juler, F.R.C.S., ophthalmic surgeon to St. Mary's Hospital, etc.

Mr. Juler, in commencing his paper, regretted the imperfect knowledge with regard to the specific cause of these conjunctival complaints, stating that we could at present in many instances only rely upon a diagnosis by the clinical features of the case.

He discussed these diseases under two heads,—the acute forms of ophthalmia and the chronic.

In the three common acute varieties—the purulent, the catarrhal, and the granular—many symptoms are similar, and no one may be characteristic; for example, the discharge may be purulent in all three cases. We are, however, able to distinguish the gonorrhoeal variety by the presence of the gonococcus of Neisser. Great intensity of the symptoms, with brawny infiltration of the lids, is much more common, too, in this variety than in the others.

Acute granular conjunctivitis is to be recognized if the "sago-grained" granulations are seen on the palpebral conjunctiva. Their absence, however, is not sufficiently trustworthy to exclude the disease, as the inflammatory infiltration during the active stage often masks these diagnostic bodies. It usually subsides into a chronic condition.

Acute catarrhal ophthalmia, though frequently severe and attended with excessive discharge and conjunctival hemorrhages, occasioning great discomfort, besides being a most contagious affection, subsides under proper treatment in about fourteen days.

Though the presence of a micro-organism has been proved, more evidence is wanted to prove it the specific cause of the disease.

Mr. Juler considered that most cases of chronic ophthalmia came under the headings of chronic catarrhal and chronic granular conjunctivitis. He entered into the question of the value of the lymphoid follicles, or so-called "trachoma capsules," as a help in the diagnosis of these complaints. He is of opinion that lymphoid follicles exist normally in most cases in the cul-de-sac, and that they are, as it were, sentinels which give warning of the approach of foreign or irritating substances and endeavor to eliminate them; consequently these follicles are liable to become inflamed either from simple or specific causes. He believes that

only in trachoma are capsules to be found in abnormal positions, as on the palpebral conjunctiva. He showed a number of photomicrographs of these bodies and of other histological changes in these membranes. One of them illustrated a follicle embedded in the substantia propria of the cornea, consecutive to a violent attack of granular ophthalmia and progressive pannus.

So-called follicular conjunctivitis, Mr. Juler regards as a simple non-contagious affection, allied to chronic catarrhal ophthalmia, but characterized besides by hyperplastic changes in the follicles. He emphasized the difficulty of distinguishing between certain cases, and pointed out that their behavior to treatment is very often the only way of arriving at a correct diagnosis.

#### HEMORRHAGE IN TYPHOID FEVER.

To the Editors of the THERAPEUTIC GAZETTE:

DEAR SIRS:—I have just read your editorial on the treatment of hemorrhage in typhoid fever. Last year I treated quite a number of cases of typhoid fever, and out of twenty-seven had four very bad cases of hemorrhage. Now, in all these I used the same plan of treatment, with the best results, having only one case in which there was a slight recurrence.

This treatment was given in a paper read by me before the Medical Society of the District of Columbia, on the general treatment of typhoid fever, and consisted of the following plan:

I immediately applied an ice-bag upon the right iliac region, interposing between the patient and the ice-bag a double layer of white flannel; and applied also a cotton bandage over the ice-bag, moderately tight, making a local compress of the ice-bag, as well as getting the effect of the cold upon the region from which I thought the hemorrhage came. At the same time I raised the hips with a small hair-pillow and removed those from under the head.

By the mouth I gave, in each case, a pill consisting of one grain of opium and one of sugar of lead, every three hours, until the patient was thoroughly under the effect of the opium; at the same time I gave an enema of one pint of ice-cold water, containing one dessert-spoonful of tannic acid. I don't think I have ever seen better results obtained from any other treatment, and can recommend the same to the profession with the greatest confidence in its efficacy.

Respectfully yours,

CHAS. G. STONE.

### NOTES ON DIABETES, TREATED WITH EXTRACT AND BY GRAFTS OF SHEEP'S PANCREAS.

BY P. WATSON WILLIAMS, M.D. (LOND.),  
Senior Assistant Physician, Bristol Royal Infirmary.

NO disease has received a larger share of attention at the hands of clinicians, pathologists, and chemists in the last fifty years than has diabetes, while the ample literature and the very diverse opinions that have been advanced by the most able observers in regard to its pathology and treatment testify to the difficulties

which surround us when we seek to explain the problems involved. Certain facts recently come to our knowledge seem at first sight to justify very important conclusions as to the real nature of the disease *diabetes*, and to indicate fresh lines of treatment as at least affording some chance of increased control over this disease.

It would serve no useful purpose were I to attempt to review and to reconcile the results of recent investigations in the region of difficulty; they are well known to all physicians who are acquainted with current medical literature, and have proved a source of perplexity to many who are better able than I am to speak on the subject; but as the question of the

treatment of pancreatic diabetes by means of the pancreas or its extracts is a matter of special interest, and more especially as the possibility of treating pancreatic diabetes by means of grafts of pancreas is likely to receive further attention in the immediate future, I think it is my duty to place on record the results in a case unsuccessfully treated by myself, and to indicate what my unfortunate experience may teach us to avoid.

Before relating my own brief experience, I would call to mind the two interesting cases of diabetes resulting from obstruction to the pancreatic duct reported by Freylan,\* which support the conclusions of Minkowski, based on his recent investigations in the diabetes resulting from destruction of the pancreas in dogs. In Freylan's first case—that of a man aged thirty-five, who was passing seventy ounces of urine, containing three per cent. of sugar—diabetes was immediately due to tubercular disease of the lungs. The pancreas was atrophied, and no trace of parenchyma was observable in the microscopic sections. The pancreatic duct was completely occluded by concretions of carbonate of lime. His second case was that of a woman passing seventy ounces of urine containing eight per cent. of glucose. Death resulted from kidney-disease, but the pancreatic duct was found blocked with calcareous detritus, and a definite calculus was found in the gland itself, while the gland only contained a few isolated nodules of normal tissue, the remainder being atrophied.

CASE I.—C. T., aged fifteen, was admitted to the Bristol Royal Infirmary on July 31, 1893.

He was in good health up to three weeks before admission, when he began to complain of thirst, and was noticed by his parents to be wasting rapidly and getting extremely weak. Patellar tendon reflexes absent; no fatty stools.

On admission he was weak,—rapidly wasting; weight, five stone nine pounds four ounces; skin dry; average daily amount of urine, seventy-seven ounces, containing 3212.1 grains of sugar and two and a half per cent. of urea; daily amount of fluid drunk, seven pints.

The case was so grave that I did not consider I was justified in waiting more than two days on a strict diet, modified by allowing brown bread, before commencing active treatment, for the amount of sugar had risen to nine per cent. in seventy-eight ounces. On August 3, therefore, he had an absolutely restricted diet with gluten bread. From this day he took

freshly-minced pancreas for seven days, then 1 drachm freshly-prepared liquid extract of pancreas three times daily with his meals, and had a drachm every time he took any food at all in the intervals, so that he never had any food without pancreatic extract.

This was continued for four days more, the urine, the amount of sugar, and the polydipsia all steadily diminishing, till on August 11 he passed only fifty-six ounces, with 4.16 per cent. of glucose. For four days he had three fluidrachms of the extract hypodermically daily (except on the first of these four days, when he had two), with practically no alteration in the symptoms; then the pancreatic extract was again resumed by the mouth, as before.

By this time the elimination of sugar amounted to about eleven hundred and eighty-eight grains daily,—i.e., was reduced to nearly one-third of what it had been,—the urine passed was about fifty ounces daily, and the polydipsia correspondingly improved.

The diet and administration of pancreatic extract remaining unaltered, he was now ordered one and a half grains of codeine daily. In seven days the sugar averaged four hundred and fifty-six grains and urine fifty ounces daily.

The pancreatic extract was now left off (August 27), as I believed that the reduction of sugar in the first instance was due to the strict dietary and in the second to codeine. No other alteration was made, but within two days the amount of sugar nearly trebled; in four days it had risen from an average of 1.9 to 7.1 per cent. But after simply resuming the pancreatic extract, it remained as high as ever, and only fell slightly on changing the gluten bread for Clarke's starchless biscuits. In the mean while he gained five pounds, but had again lost four pounds in weight.

On September 18 the codeine was increased to two and a half grains daily, but without benefit. Without further alteration, the freshly-prepared glycerin pancreatic extract by the mouth was discontinued on September 20, and 1 drachm daily of pancreatic extract, prepared in Paris by Brown-Séguard and D'Arsonval's process, was given hypodermically for eleven days. The amount of sugar eliminated rather increased, and here the treatment by pancreatic extract was left off. The boy was—in spite of a very fair trial of pancreatic extract both by the mouth and under the skin, combined with strictest regimen, and both without codeine and subsequently with two and a half grains daily—practically in the same position as on

\* *Berl. Klin. Woch.*, No. 6, 1893.

admission. He was passing 8.2 per cent. of sugar in sixty-six ounces of urine daily.

On October 6 the codeine was increased by four grains a day. In six days' time he began to be a little sleepy in the daytime, although getting up every day. There was a slight diminution in the amount of sugar eliminated (6.2 per cent. in about sixty ounces of urine).

On October 14 I obtained a supply of freshly-prepared orchitic fluid, procured from a young bull by D'Arsonval's process by my friend Dr. Pagan Lowe, of Bath, and without any other alteration in the conditions, the patient had 1 drachm daily injected hypodermically, and as he felt so much brighter and better, this was continued, and although the amount of sugar passed was at first increased, it again decreased to about 5.5 per cent. in fifty-five ounces.

*October 26.*—The codeine discontinued, but the amount of sugar so greatly increased that in twelve days I felt it advisable to give morphine ( $\frac{3}{4}$  grain daily at first, subsequently less).

At first the effect of the morphine was very satisfactory, but about December 17 it appeared to be losing its power of controlling the diabetes, and once more the glucose rose to 8.3 per cent. in eighty ounces of urine.

The advisability of resorting to grafts of sheep's pancreas had occurred to me, and my medical colleagues, who had kindly seen this case with me frequently during the time the patient was under my care, agreed with me that the case was one which offered some chance of benefit from such a procedure, seeing that laboratory investigations of Minkowski and others appeared to lend some hope that the patient might be favorably modified.

I had previously visited a neighboring slaughter-house in order to familiarize myself with the best method of rapidly extracting the pancreas from a sheep. By suspending the carcass by the hinder extremities, one had only to open the abdomen and allow the intestines and stomach to fall down, and the pancreas was exposed and readily removed.

On December 20 my surgical colleague, Mr. Harsant, placed the patient under chloroform, while I extracted the pancreas with strict aseptic precautions from a freshly-slaughtered sheep, so that by the time the patient was anæsthetized the pancreas was at hand, and three pieces, each the size of a Brazil-nut, had been grafted into the subcutaneous tissues of the breast and abdomen, and the operation completed within twenty minutes of the death of the sheep. The patient was under the anæsthetic a quarter of an hour. The wounds were dressed

antiseptically. He passed one hundred and sixteen ounces of urine, containing 7.4 per cent. of sugar in the following twenty-four hours.

On December 22 ninety-five ounces of urine containing 3.12 per cent. of sugar were passed. The incisions appeared perfectly healthy, and Mr. Harsant considered that they were healing by first intention; but he felt very depressed and weaker and drowsy, and there was every indication of coma supervening. The urine yielded a more decided acetone reaction, although this had been noticed in a less degree for some weeks. With a view to prevent the onset of coma, bicarbonate of potassium was administered and an aperient ordered.

On the 23d he died comatose. Large doses of citrate of potassium by the mouth, combined with thirty grains of bicarbonate of sodium, given hypodermically in three doses, had had no effect whatever. Oxygen inhalations and oxygen water had also been tried.

*At the autopsy* on the following day the heart and lungs were found to be normal, but the liver and kidneys were enlarged and fatty.

The pancreas only weighed half an ounce in its capsule. It was small, shrivelled in appearance, and seemed to be little else than fibrous tissue. Examination of sections of the pancreas showed that almost all the secreting structure had disappeared, and that the gland consisted of little else but fibrous stroma.

The grafts had apparently failed to become united with the tissues around, and though the incisions in the skin had apparently united, numerous micrococci were found on microscopical examination, but the autopsy was made sixteen hours after death from diabetic coma.

*Remarks.*—I think that the considerable number of cases of diabetes that have now been recorded as having been treated with pancreatic extract by the mouth have shown that practically nothing can be expected from such treatment. In the case of C. T. the method received a very fair trial, the freshly-prepared extract being given first every time the patient took any food whatever, and subsequently by cutaneous injection.

Of course, in some respects this was not a typical case of pancreatic diabetes, inasmuch as the amount of urine was not very excessive and there were no fatty stools, but I think the history of the case and the post-mortem examination of the pancreas leave no doubt that it was rightly considered to be pancreatic diabetes, and one that presented all the conditions that might lead one to hope for a beneficial re-

sult from successful grafting of the pancreas, if anything can be hoped for in this direction at all.

Failure was possibly due to obtaining the graft from a sheep that had been killed by bleeding, and I fear may have been rendered more likely from the administration of the anæsthetic. If I ever again felt justified in resorting to pancreatic grafts in a similar case, I should obtain them from a living animal anæsthetized, and dispense with the anæsthetic altogether.

CASE II.—W. H., male, aged forty-seven. Symptoms of diabetes began about February, 1892. In November he came under me, when I took him into the Royal Infirmary. He was passing sixty-five ounces of urine daily, containing about 1245 grains of sugar. After a restricted diet, and while taking small doses of phosphorus and arsenic, the amount of sugar increased to 1800 grains daily. On the same diet, but taking 1 grain of codeine daily for four days, the amount of urine increased to eighty-eight ounces, with 1920 grains of sugar daily; but after persisting in this course of treatment for twenty-nine days the sugar eliminated amounted to 1742 grains daily. At this point (January 12, 1893) I gave him 40 minims of pancreatic extract (the freshly-prepared glycerin extract) daily as a hypodermic injection. After a few days the extract was given instead by the mouth for some days, but under the treatment by pancreatic extract his condition remained in *status quo*. The patient was then placed on codeine, with strict diet, and he improved greatly, and eventually completely recovered. In this case the fresh pancreatic extract, whether given hypodermically or by the mouth, was valueless, yet codeine and dieting brought about complete recovery.

CASE.—C. T., on admission, first two days, average amount of sugar passed in twenty-four hours, 3212.1 grains.

August 11.—After four days' strict diet and pancreatic extract by mouth, average amount of sugar passed in twenty-four hours, 978.8 grains.

August 15 and 16.—After four days' strict diet and pancreatic extract hypodermically, average amount of sugar passed in twenty-four hours, 983.8 grains.

August 18 and 19.—After pancreatic extract resumed by the mouth, average amount of sugar passed in twenty-four hours, 1188 grains.

August 26.—After seven days of pancreatic extract by mouth, strict diet, and codeine  $1\frac{1}{2}$  grains daily, average amount of sugar passed in twenty-four hours, 456 grains.

August 31.—After four days of same conditions, except that the pancreatic extract was discontinued, average amount of sugar passed in twenty-four hours, 1872 grains.

September 18.—After conditions of August 26 had been resumed for eighteen days, average amount of sugar passed in twenty-four hours, 1733 grains.

#### NOTES ON SOME NEW DRUGS USEFUL IN OPHTHALMOLOGY.

READ BEFORE THE SECTION OF OPHTHALMOLOGY, BRITISH MEDICAL ASSOCIATION, BRISTOL MEETING, 1894.

BY T. J. BOKENHAM, M.R.C.S., L.R.C.P.,  
Research Scholar, British Medical Association.

DURING the past year or more I have made it my business to test the utility of several drugs of recent introduction. The properties of some of these seem to indicate that they may occupy a prominent place in ocular therapeutics, and I take this opportunity of bringing them more prominently into notice, so that others who may have more extensive opportunities of observation than myself may add their testimony to my own. Without further prelude I will now proceed to my subject.

*Scopolamine*.—Some time during 1889 a rhizome appeared in the market, imported from Germany, where it was stated to be indigenous. It was introduced as a new and cheap source of atropine, and its juice certainly had powerful mydriatic properties. It was identified as the rhizome of *Scopolia Carniolica*, and its chemistry was investigated by Dunstan and Chaston on behalf of the Pharmaceutical Society. These observers found it to contain almost pure hyoscyamine, with a mere trace of hyoscyne, and no other alkaloids. As, however, the chemistry of the *Solanaceæ* is wrapped in considerable obscurity, owing to the ease with which one alkaloid passes into another in process of isolation, the chief point of interest in these researches is the proof that the rhizome contained a mydriatic alkaloid chemically indistinguishable from hyoscyamine.\*

My attention was first drawn to this new drug in 1890, when I received a specimen of the new alkaloid from Messrs. Burroughs and Wellcome. I was at that time working in Dr. Lauder Brunton's laboratory at St. Bartholomew's Hospital, and I there made several ob-

\* *Pharm. Journ.*, December 14, 1889; Schmidt, *Pharm. Zeit.*, September 25, 1889; Siebert, *Arch. der Pharm.*, February 20, 1890.

servations as to its effect on blood-pressure, pulse, etc. Its general action on animals was not, however, thoroughly tested, as rodents—the only animals I had at my disposal—are not easily susceptible to the action of the atropoid alkaloids. On myself the hypodermic injection of .01 grain was practically without effect, producing neither excitement, dryness of the throat, nor dilatation of the pupil. Some clinical investigations by Sir Dyce Duckworth also seemed to show that the drug had many of the advantages of atropine, while not sharing all its drawbacks.

In rabbits and cats under anaesthesia, tracings of the carotid pressure before and after the injection of a solution of scopolamine showed that the drug in moderate doses had little or no effect either on the rapidity or force of the heart-beat. After a dose which, had it been atropine, would have quickened the heart (cat) by paralysis of the inhibitory fibres of the vagus, the pulse was slightly slowed, and it was only after very large doses that acceleration was observed, and even then the vago-inhibitory effect was not completely abolished.

Its mydriatic effect was tested both in animals and on myself. In my own case a solution of 1 to 1000 was employed, and I found that instillation of 2 or 3 drops twice, at intervals of half an hour, was sufficient to produce complete dilatation of the pupil and paralysis of accommodation. No unpleasant phenomena accompanied this action, my accommodation being almost restored after thirty-six hours, and the pupil being normal in a little less than three days; only one eye was drugged.

Seeing that scopolamine had again recently attracted the attention of foreign ophthalmologists, notably of Raehlmann,\* who reported most favorably on its action as a paralyzant of accommodation, I procured a fresh specimen of the hydrobromate, through Messrs. Burroughs and Wellcome. This I have used in a number of cases where I should ordinarily have employed belladonna. With a strength of 1 to 250 I find that three instillations within an hour are sufficient to produce complete cycloplegia, so that an error of refraction can be estimated with accuracy. In a fair number of observations I have not once seen the production of undesirable complications, such as excitement, dryness of the throat, or erythema, even in children, who are most susceptible to the action of atropine. I have generally, my observations being concluded, introduced an eserine disk (Wyeth), in order to hasten the

return of accommodative power, but I do not know that this is quite necessary, for in three days at most the eyes may be considered normal.

Personally, I have had but little experience of scopolamine for other purposes than to facilitate the estimation of refraction. Raehlmann, however, speaks of its utility in inflammatory conditions of the cornea, phlyctenular keratitis, corneal ulcer, iritis, etc., the drug being well borne where atropine was not tolerated, and producing no rise of tension even when used day after day.

My own experience of the strength necessary coincides with that of other observers. A strength of 1 to 250 and 1 to 500 is quite sufficient for all purposes for which atropine can be required, and an even weaker solution is often admissible.

I must add also the results obtained by Pooley (*THERAPEUTIC GAZETTE*, March, 1894). This observer, while considering scopolamine as useful in any cases where an atropoid action is desired, yet utters a note of warning necessitated by his own experience.

In three cases, each of which had obtained the drug from a chemist and made the instillations personally, unpleasant phenomena resembling those of atropine-poisoning ensued. It is possible, however, that the solution was used with undue frequency or too liberally, as these are the only three observations of a similar nature on record.

To conclude, I would counsel a trial of scopolamine,—

1. Because its action is slightly more powerful than that of homatropine.
2. Because its action is more rapid than that of atropine and a less quantity is required to produce the same effect.
3. Because its action passes off with greater rapidity than that of atropine.
4. Because toxic symptoms seem little likely to ensue from its use.

*Tropa-Cocaine.*—Quite recently I have brought a number of my observations with this drug before the Ophthalmological Society, so that on this occasion I can be quite brief. My experience with tropa-cocaine as a local anaesthetic has since the paper mentioned increased considerably, and I am pleased to say that my opinion as to the utility of the drug for this purpose remains unaltered. Its great value resides in the fact that by its aid local anaesthesia can be produced uncomplicated by dilatation of the pupil or loss of accommodative power. This is a great boon to, say, a patient who only needs the painless removal of a foreign

\* *Klin. Monatsb. für Augen.*, February, 1893.

body. I formerly employed the drug in tabloid form, but I think that it is perhaps less irritating on first application if used in solution, a strength of three per cent. being quite sufficient for most purposes.

*TREPHINING FOR MIDDLE MENINGEAL HEMORRHAGE WITHOUT FRACTURE OF THE SKULL.*

READ AT THE FEBRUARY MEETING OF THE PHILADELPHIA NEUROLOGICAL SOCIETY, 1894.

BY WILLIAM J. TAYLOR, M.D., PHILADELPHIA, PA.,  
Professor of Orthopædic Surgery in the Philadelphia Polyclinic;  
Attending Surgeon to St. Agnes's Hospital; Assistant  
Surgeon to the Orthopædic Hospital and  
Infirmary for Nervous Diseases.

**E**XTRADURAL hemorrhage without fracture of the skull is due in nearly every instance to rupture of the middle meningeal artery or one of its branches. This artery springs from the internal maxillary and enters the cranium through the foramen spinosum; it then divides into two branches,—the anterior and the posterior. The anterior or larger branch crosses the great ala of the sphenoid, and reaches the groove or canal in the anterior inferior angle of the parietal bone, when it divides into branches, to be distributed over the dura mater and inner surface of the cranium. The posterior branch crosses the squamous portion of the temporal bone, and on the inner surface of the parietal bone divides into branches to supply the posterior part of the dura and cranium.

One or both branches of the artery may be ruptured; the main trunk is seldom injured. Very occasionally the vessels upon the opposite side of the skull from the point of injury are torn by counter-stroke, and when this occurs it is only by the localizing symptoms that we are able to find the bleeding vessel. The cause is usually a fall upon the head, and often from a very short distance, or it may be due to a blow of the fist or some heavy instrument. The amount of violence necessary to produce rupture of these vessels is frequently very slight, and at times not sufficient to cause the individual to fall to the ground if struck a blow on the head, or to produce even momentary unconsciousness.

The adhesions between the dura mater and the bone are weakest in the temporal fossa, and it is for this reason that the artery may be ruptured by a force which is sufficient to detach the dura, yet not so violent as to fracture the bone.

The anterior branch is frequently in a groove,

and it is most often torn as it crosses the anterior inferior angle of the parietal bone.

There often intervenes between the time of the stunning, or it may be insensibility, produced by the original violence a period of consciousness, but this is not always so. Jacobson mentions this as occurring in thirty-two out of sixty-three cases of middle meningeal hemorrhage from all causes. This may last for only a few moments, and can thus be readily overlooked, or it may exist for some hours or even days. This period of consciousness, which finally lapses into coma, is by far the most important symptom, and is, indeed, worth all the other symptoms combined in enabling us to form a correct diagnosis. Paralysis, or rather hemiplegia, may then come on, which gradually extends as the clot increases in size and presses upon the cortical motor centres. If the amount of hemorrhage be small, we may only have evidences of a cortical irritation in the form of convulsive movements of the arm and leg of one side. This cortical irritation was pronounced in one of the cases which I present to-night. There may also be general convulsions. The hemiplegia is usually upon the side opposite to that of the injury; but occasionally the vessel upon the other side of the skull is ruptured by counter-stroke, and then we would have paralysis upon the same side as the injury itself, although I believe there are some very rare instances of paralysis on the same side as the injury when the hemorrhage is extradural.

The pupils may be contracted, due to the concussion of the injury, or dilated, if the clot be large and pressing upon the base of the brain. When one pupil is dilated widely, especially if it be on the same side as the injury, it is of the greatest importance, as showing pressure of a large clot.

The pulse, as a rule, is frequent. Unconsciousness varies with the amount of hemorrhage; it may be deep coma from the first, as in Case II., or the patient may possibly be roused and move the limbs when disturbed. Respiration is slow and stertorous. The temperature rises rapidly to 101°, 102°, 103°, and even 104° F.

Whenever we have a case of injury to the head presenting these symptoms, and especially if there be a period of consciousness between the time of the accident and the onset of deepening coma, it is our duty to trephine the skull and search for the source of hemorrhage. We must be guided in so doing by the localizing symptoms and not by the side of the head upon which the injury has been received.

Weisman (*Deutsche Zeitschr. f. Chir.*, Band xxi. Heft 1-3; Band xxii. Heft 2; there is an extended review of this article in the *Annals of Surgery*, December, 1885, p. 502), who has written the most elaborate paper upon this subject, states that in all instances where we have, first, an interval of consciousness between the concussion and the onset of coma; second, hemiplegia; third, an infrequent and hard pulse; and, fourth, slow and embarrassed respiration, with stertor, whether there be a lesion of the skull or not, even of the opposite side, we must trephine.

He further states that when aphasia is present there is an extension of the clot towards the front, when there are disorders of sensibility there is an extension backward, and if there be paralysis of the third pair the extension is towards the base of the brain.

Mr. W. H. A. Jacobson, in his very elaborate paper in "Guy's Hospital Reports for 1885-86," records the history of eight cases of middle meningeal hemorrhage without fracture of the skull.

Seven of these cases received the injuries by falls upon the head and one by a blow from a loaded whip-handle. All of the cases in which a trephine opening was made in the skull—four in number—recovered (Nos. 8, 9, 10, and 19). In the four cases where death ensued (Nos. 2, 3, 20, and 55) no attempt was made to trephine the skull. In three of the latter cases there was an interval of consciousness after the concussion, lasting for some hours. Coma came on only after the patients were in bed and asleep. In one (No. 55) there was no interval of consciousness, as the man was insensible from the first and died in forty-eight hours. The four cases of recovery, and in which trephining was done, were conscious for a period of time before the pressure-symptoms manifested themselves. In one the vessel upon the opposite side of the head from the point of injury was ruptured by a counter-stroke.

Our object in trephining the skull is twofold: first, to stop the hemorrhage from the ruptured vessel; and, second, to relieve the intracranial pressure from the rapidly-enlarging blood-clot.

The opening in the skull should be made with a medium-sized trephine one and a quarter inches behind the external angular process of the temporal bone, on a level with the upper border of the orbit, for at this point the anterior branch of the middle meningeal artery is most readily exposed.

A rongeur forceps should then be used to enlarge the opening sufficiently to enable us to

find the source of hemorrhage. If no clot or evidence of bleeding is found, another and similar button of bone should be removed upon the same side of the skull, just below the parietal bosse, on the same level; this will expose the posterior branch of the artery.

As it is almost impossible to say whether the clot is extradural or subdural in the same area by the localizing symptoms alone, an opening should always be made in the dura mater to determine this point, provided the clot is not found directly beneath the bone. This dural opening does not materially increase the danger of the operation when all due antiseptic precautions have been followed, and it should be carefully closed by catgut sutures.

When the clot is found it should be removed by a stream of plain boiled water, allowed to flow freely over the part, aided, if need be, by gentle sponging. If the vessel is still bleeding, it should be ligated with catgut.

When there is difficulty in controlling the hemorrhage by simple circular ligation, a curved needle threaded with catgut should be passed beneath the vessel through the thickness of the dura and securely tied.

When the on-coming coma has been slow to develop, it may be due to a rupture of some one or more of the smaller branches of the vessels, and, if so, it may not be possible to directly locate and ligate the source of hemorrhage, and it may only be controlled by packing with gauze.

When the bleeding vessel has been torn off as it emerges from the groove in the bone, it may be necessary to cut away the bone with forceps and, if need be, pack with iodoform gauze.

In a case reported by Dr. Ransohoff (*Annals of Surgery*, 1890, vol. xii. p. 116) secondary hemorrhage occurred, and it was found necessary to ligate the external carotid artery to control the bleeding; this should be done if it is found impossible to control the hemorrhage by packing.

Drainage by iodoform gauze should always be used, as the amount of wound discharge will be very free for the first day or two. Silk-worm-gut sutures are best; it is also best to leave one untied at the point at which the gauze drain emerges; this may be tied when the drain is removed, and complete the closure of the wound.

When rupture of both branches of the artery has occurred, or when drainage from the anterior trephine opening is not sufficiently free, a second opening should be made below the

parietal bosse, and a gauze drain carried from the anterior to the posterior opening.

Dr. J. B. Deaver, in a case of fissure fracture, with rupture of this artery, did this, with most satisfactory results (*Journal of Mental and Nervous Diseases*, February, 1890).

I had thought trephining for hemorrhage from the middle meningeal artery without fracture of the bone a modern procedure, but Mr. Jacobson records a case treated in this manner by Mr. J. Hill on February 27, 1751. The results in this case were so successful that, twenty years after, this man was reported as alive and in good health.

**CASE I.—Middle Meningeal Hemorrhage without Fracture; Trephining; Death; Autopsy.**—The first case which I have to report is that of a man, aged forty-eight, who was admitted to my service at St. Agnes's Hospital on the morning of May 8, 1893. He had fallen down-stairs the night before and struck upon his head. Dr. Theo. Sprissler, who first saw him, was under the impression that his accident was due to some form of cerebral irritation producing giddiness, for there seemed to be no good reason for his fall, and he had had a similar attack some six or eight weeks before. When picked up by his friends he was totally unconscious, and remained so for a few minutes, but soon revived and got upon his feet and walked around the room. Shortly after this—I am unable to state the exact time, but within a half-hour—he became stupid, sank down, and again became unconscious; in this condition he was admitted to the hospital. He could be roused by loud calling and shaking sufficiently to say that he felt very well, but would lapse at once into stupor.

I saw him first at 5.30 P.M., May 8, some eighteen or twenty hours after his accident; there was no evidence whatever of fracture; the pupils were equally contracted; the left eyelid was discolored by extravasated blood, but not so the conjunctiva; there was a bruise just above the left ear.

His breathing was full and labored, with some drawing in of the angle of the mouth on the left side and puffing of the cheek. The left arm and leg were paretic, although he could move them at will. The right arm and leg were in almost constant convulsive movement; these movements were slight, but persistent and unmistakable.

As I had seen him during the temporary absence of my colleague, Dr. J. B. Deaver, I gave general directions and went home. At 10 P.M. I was again called to see him, as his condition had only changed for the worse.

All his symptoms were now pronounced and his temperature had risen to 101° F. Evidently there was intracranial hemorrhage, and delay was no longer permissible.

After the head was shaved and thoroughly disinfected, I deliberated for some time as to my course of action. There was undoubted cerebral irritation on the left side,—probably dural,—as was shown by the convulsive movements of the right side, but there was paralysis of the left angle of the mouth and paresis of the left side. Thinking this might be the chief source of trouble, I removed a button of bone with a one-inch trephine at a point one and one-fourth inches above and one and one-fourth inches behind the angular process of the orbit. The anterior branch of the middle meningeal artery was readily seen; it was intact and there was no evidence of bleeding or clot. The dura did not bulge, but I opened it with a small semicircular incision, and by so doing liberated a large quantity—at least one ounce—of clear cerebro-spinal fluid. The dura was much thickened; the cerebral convolutions appeared normal, although the vessels of the pia were somewhat enlarged. The opening in the dura was then united by catgut sutures and the wound in the scalp closed.

I now trephined at a corresponding point on the left side of the head, and upon removing the button of bone a large clot was at once apparent. The anterior branch of the middle meningeal artery was seen to be ruptured and was bleeding freely in little sprits. At least one ounce of dark, clotted blood escaped and welled up from the deeper parts of the skull. The opening in the bone was enlarged with a rongeur forceps sufficiently to enable me to pass a catgut suture under the bleeding vessel and through the dura, thus effectually arresting the hemorrhage. There was some free bleeding from the edge of the bone, but packing with iodoform gauze arrested this readily.

The cerebral irritation improved at once, the convulsive movements ceased, and he reacted quite well from the shock of the operation. He soon began to weaken, however, and gradually sank until his death at 11 P.M., May 10, 1893, forty-eight hours after the operation and seventy-two hours from the time of the accident.

A post-mortem examination was made at 11 A.M., May 11, 1893, just twelve hours after death. The head alone was examined. The wounds were in good condition; that of the right side contained a small organizing clot; that on the left side showed the iodoform

packing and a small clot. The scalp was slightly œdematous. On opening the cranium, the dura mater was found adherent to the under surface of the skull in several places, and at many points adherent to the cerebral convolution; especially was this the case along the superior longitudinal sinus about the region of the leg-centre. The vessels were injected and full of blood. The brain was soft and, with the pia mater, much inflamed. Over the region of the arm- and face-centre, on the left side, was a mass of lymph. The left ventricle was full of dark, blood-stained fluid: There had been a small hemorrhage into the anterior horn of the right ventricle, and in the velum interpositum a hard clot the size of a small pea. I now learned from Dr. Sprissler, who was present at the autopsy, that four weeks before, the man had had a slight stroke of paralysis; he staggered, swayed to and fro for a moment, and then fell unconscious. From this he gradually recovered, but there had been no recovery of consciousness, followed by relapse into unconsciousness, as in the present instance. The cerebellum was soft and congested; the anterior branch of the middle meningeal had ruptured.

Although results, so far as the recovery of the patient was concerned, were bad, the diagnosis of meningeal rupture was confirmed by operation, and had the extent of the former injury been less his chances of recovery would have been good.

CASE II.—*Extensive Hemorrhage from both Branches of the Middle Meningeal, without Fracture.*—(This patient was under the care of Dr. W. W. Keen, and through his kindness I am able to present it to-night.) A man aged fifty was admitted to St. Agnes's Hospital at 6.30 A.M. on June 30, 1892, having fallen, a few minutes before, from a hay-loft, striking on the top of his head. When Dr. Keen saw him at 7.30 A.M. he was entirely unconscious, with puffing respiration, 38 to the minute. The lungs were filling with mucus, and the pulse was 100 and of only fair quality. The left pupil was slightly more dilated than the right and rather more sluggish in its reaction to light. In the middle line of the head, at the vertex, was a lacerated scalp wound 2.5 inches long, and slightly to the left of the middle line, over the occiput, another similar scar one inch long. In neither of these wounds was the bone exposed. An incision revealed the fact that there was no fracture. The patient did not move at all, excepting during the making of these incisions, at which time he moved the trunk a little uneasily, but

did not move the extremities. He had had, slight bleeding from the left nostril, but no discharge of cerebro-spinal fluid from the nasal cavity, nor any discharge whatever from either the mouth or the ears. Dr. Keen therefore felt that fracture of the base could be excluded; fracture of the vault was excluded by direct examination; and although there was no history as to whether any lucid interval had existed between the fall and the unconsciousness, it seemed to him that the cause of the trouble could only be rupture of the middle meningeal artery, and based his diagnosis of the side on which to expect the lesion upon the state of the pupils. Accordingly he trephined at a point one and a quarter inches behind and one inch above the external angular process. The instant the button of bone was removed a dark clot exuded, and so rapidly as to leave no doubt that it was a very large one. As rapidly as possible the bone was gnawed away, upward and backward, with a rongeur forceps, when he found an enormous clot, extending from two inches from the middle line down to the base of the brain, and from one-half an inch back of the external angular process to the occiput. On turning out this clot the anterior branch of the middle meningeal was seen to be ruptured and bleeding at two points,—one a little below the opening and the other a little higher up,—and the posterior branch was likewise ruptured at two points; all four of these were secured by ligatures passed through the dura. The condition of the patient when first seen was very doubtful as to recovery. He died a few minutes after the vessels were secured.

Here the amount of violence inflicted by the fall was too great to permit of benefit from operative interference, as both branches of the artery were ruptured and the amount of hemorrhage and injury to the brain so excessive that recovery was impossible.

For Case III. I am also indebted to Dr. Wharton Sinkler and Dr. W. W. Keen for permission to report, and also for the pleasure of seeing the patient with the latter and Dr. Cross, of Jenkintown.

Although this is not a case of meningeal, but one of subdural hemorrhage, the symptoms were such as to lead us to suppose that the former condition was present.

CASE III.—*Intracranial (Cerebral) Hemorrhage, involving the Fibres from the Cuneus, and producing Hemianopsia.*—This patient was a slender woman of sixty-five, who had been ailing from grippe and its sequels for about two years, and who had been recently subject

to attacks of vertigo. On December 28, 1893, when going up-stairs, she fell backward from near the top of the flight, striking on the back of her head. There was no cut, nor any lump, and the only way in which the presumed site of the blow could be fixed was by her wincing when pressure was made over the *right* occiput, and also the unconscious movements of her right hand to that spot, which seemed to give her discomfort. She was picked up unconscious and put to bed. The next day Dr. Cross noticed, in examining her pupils, that when a candle was carried to the *left* of the middle line she followed it, although she was not conscious enough to make known sensations or manifest desires. When the light was carried to the right of the middle line she did not follow it. This was several times repeated, so that Dr. Cross judged that she had hemianopsia, the right half of the field not being seen. There was no paralysis at first, but gradually, in about thirty-six hours after the accident, she became comatose and did not move any of her extremities.

When we saw her, at the request of Dr. Cross and Dr. Sinkler, who had been called in consultation with Dr. Cross, the chest had filled up with mucus and she was evidently dying. It was decided, therefore, to do nothing, and shortly afterwards she expired. The diagnosis was a clot of blood, probably extradural, from the middle meningeal, or possibly subdural, and involving fibres from the cuneus.

*Post-Mortem.*—I had the good fortune to make the post-mortem examination fourteen hours after death. The head only was examined. There was no evidence of her having struck over the right occiput, so far as the condition of the scalp and underlying tissues would show. The middle meningeal was not ruptured. The meninges were in the early stages of inflammation. A clot of blood nearly as large as an egg was found in the cortex corresponding to the left parietal eminence, and extending deeply into the cerebral substance, so as to involve the fibres from the left cuneus.

*Remarks by Dr. Keen.*—"When I first saw the patient, Dr. Cross's very shrewd and accurate observation of the fault of vision put us on the right track for the proper surgical treatment had the patient been in suitable condition. The right half of each field being blind, the left half of each retina was the blind portion, these two being supplied from the left cuneus. Had we followed the indications of tenderness over the right occiput and her apparent annoyance

from some trouble at this point, as shown by her unconsciously putting her hand there, we should have been led far astray. Basing the diagnosis on cerebral localization, I should have trephined, as I said to Dr. Cross and Dr. Taylor, at a point immediately below the left parietal eminence, in order to reach the posterior branch of the middle meningeal, which I deemed most likely the ruptured vessel.

"The post-mortem makes it more probable that the rupture of the blood-vessel resulting in the cortical clot was the cause and not the result of her fall. The location of the clot, however, was correctly diagnosed, although its source, of course, could not be absolutely known. The point at which I should have trephined would have been the correct one; but, in view of the origin and size of the clot and of the patient's age and feeble condition, it is very doubtful whether she would have recovered, even had operation been done immediately after the accident. Had the clot been in the ganglia at the base of the brain, as is more common in ordinary cerebral apoplexy, there would have been, of course, a hemiplegia. This rendered the diagnosis of rupture of the middle meningeal posterior branch the more likely one."

116 SOUTH EIGHTEENTH STREET.

#### *THERAPEUTIC NOTES ON WHOOPING-COUGH.*

READ BEFORE THE PENNSYLVANIA STATE MEDICAL SOCIETY,  
MAY 18, 1894.

BY W. C. HOLLOPETER, A.M., M.D.,

Physician to the Methodist Episcopal Hospital; Clinical Professor  
of Diseases of Children in the Medico-Chirurgical College.

THE prevalence of an unusually severe epidemic throughout our city and the chaotic state of our therapeutic measures are my reasons for this brief paper. The therapeutics of whooping-cough is boundless, and, like phthisis and diphtheria, it covers nearly the whole domain of the Pharmacopœia. This fact alone assures me that we, as yet, have found no specific for it. Those remedies most in vogue are the antispasmodics and the germicides, and they have all been faithfully tried one after the other, and, to a certain extent, seem to have some value. It is not my purpose to enumerate the various remedies that have been used and have become exalted because they have found favor in some practitioners' hands.

We want a specific for this specific disease, for such I regard it, and I feel sure that it will be found among the two classes I mentioned

above,—the antispasmodics and the germicides. Whooping-cough is an exceedingly fatal disease; by most authorities regarded the most fatal of all the diseases of children under one year. The fatality, however, is not limited to the first year of life alone; it continues to manifest itself long after this period, in broken health of all kinds referable to the respiratory, intestinal, as well as the various glandular, organs. I am sure we are all familiar with the more severe sequelæ of whooping-cough. The emaciated child suffering from gastro-intestinal catarrh of a chronic type, the various cheesy glands, the acute or chronic nephritis, the purulent otorrhœa, the chronic bronchitis, the broncho-pneumonias, and pleurisies go to form a goodly portion of our every-day routine practice; and all of these come to us because of the widely-mistaken idea that we can do but little, if anything, in the cure of the original disease. I am at a loss to know why the majority of people regard this disease so lightly,—that it is harmless, that it is self-limited, and does not require any remedial measures,—unless our treatment in the past has been so unsatisfactory and so unscientific! Again, I believe this unsettled state of affairs among the laity as to its incurability is traceable to our own actions in our careless and slovenly manner in the general management of the disorder.

This is not the place to discuss the etiology of the disease, yet this much seems necessary to the correct understanding of the subject. Whooping-cough has a striking parallel to diphtheria, in that it has in its early stages a local manifestation. It has a strong tendency to fasten itself on the throat. How long this period exists I do not know to a certainty; no more than we know just how long diphtheria is purely a local throat poison; yet there is a period in whooping-cough, as there is in diphtheria, long or short, in which the virus—if it could be recognized—could be destroyed and the disease cut short. Aborting cases thus within two weeks—and it is not unusual—explains the number of reported cures made by germicidal remedies. I have notes of two cases which I can recall in which the characteristic whoops commenced at once with the general catarrhal symptoms and were cut short by a hydrogen peroxide gargle. I think these two cases illustrate very strongly the fact that the germs of the disease will locate in part on the mucous membrane of the respiratory passage, and bring about a nerve discharge which ends in the characteristic whoop. In my treatment of this disease I find the greatest necessity in recognizing the nature of the trouble

early in the catarrhal stage. If I can satisfy myself that I am dealing with a case of pertussis, my methods of procedure are much different from what they would be if the case were well advanced. We must remember that the two stages are not sharply defined. We have many cases without the catarrhal stage at all, as we have many cases that do not whoop. Children under one year with the disease do not whoop, as a rule, and older children do not always possess the catarrhal indications, yet may whoop vigorously at the very outset of the disease.

The anatomical structure of the infantile larynx under all catarrhal inflammation is convulsive and suggests the nervous mimicry so very difficult of recognition.

The early diagnosis of the disease is of vast importance, as upon it depends the success of the treatment.

The diagnostic point prior to the whooping stage, enunciated by Eustace Smith,—viz., “If the child be made to bend back the head, so that his face becomes almost horizontal and the eyes look straight upward at the ceiling above, a venous hum, varying in intensity according to the size and position of the diseased glands, is heard with the stethoscope placed upon the upper bone of the sternum. As the chin is now slowly depressed, the hum becomes less loudly audible, and ceases shortly before the head reaches its ordinary position,”—has not been very satisfactory. It is true that we do not recognize the hum made thus by the enlarged bronchial glands, but it occurs long after other symptoms are manifest, thus vitiating the importance of this particular symptom.

I have for several years been able to place considerable value on the peculiar puffiness of the mucous membrane of the eyes and the swollen or oedematous condition of the whole face, almost dusky; this condition may exist for days before the catarrhal symptoms have extended throughout the respiratory mucous membrane. The cough at this stage may not be at all suggestive; it may be, in fact, purely bronchial. This symptom of fulness about the eyes, which is quite as constant as in measles, would, in fact, suggest measles as well as pertussis, and with measles it is closely associated and must be differentiated. As we are able to diagnose measles by their appearance first on the hard palate, so I contend we may diagnose whooping-cough, in its earliest stage, by the characteristic swollen condition of the eyes and face. I insist upon this factor as of the greatest importance, as its recognition will en-

able us to institute specific treatment early when the disease is yet local and may be brought more speedily under control. During the last five years I have had under my control upward of two hundred cases of whooping-cough. Of the majority of these cases I kept an indifferent clinical record, from which I deduce the results embodied in this paper. Pertussis, as we all know, is a notoriously unsatisfactory disease to manage, and if we put our whole confidence on a single remedy we are likely to meet with keen disappointment; thus the good reputation as well as the disgrace of a drug comes about. The drugs I have found most efficient in the catarrhal stage have been hydrogen peroxide in sterilizing the naso-pharynx, and assafoetida occasionally used for the paroxysms. Belladonna, also, is to a high degree beneficial in young children, and should be placed first. This I push until I get the full toxic effects, when I am generally rewarded with less of the suggestive characteristics of the cough.

To be more explicit, I will detail the methods of procedure in a family in which I have instituted my idea of thorough treatment. A child of four years attending kindergarten was brought to me with a suspicious cough. The history was given of an exposure of over two weeks prior. The child coughed for a few days, more at night, was feverish during the evenings, with slightly swollen eyelids, this suggesting the nature of the impending trouble. I ordered hydrogen peroxide and pure glycerin, equal parts; this was well diluted and thoroughly sprayed through the naso-pharynx every four hours. The diet was light and digestible; out-door life was encouraged, except on windy days. All excitement was avoided, so as not to precipitate any additional paroxysms. At night the child was placed in a large, well-ventilated room, and over its cot was erected a mosquito-netting, so as to prevent any unusual draught. This procedure I have found highly beneficial, as it materially lessens the number of the nocturnal paroxysms. When the cough was fully established and was accompanied by eructations of stringy mucus, I commenced the exhibition of *mistura assafoetida*,  $\frac{1}{2}$  drachm every two hours. The record of the paroxysmal stage was as follows: First week averaged six coughing spells per day; second week averaged ten spells per day; third week, four paroxysms; and fourth and fifth weeks averaged about two paroxysms during the twenty-four hours. When the younger brother, but eight weeks old, commenced to show evidence of the disease, I first used hydrogen peroxide, as in the older brother,

and immediately followed it with *assafoetida*. This case continued scarcely four weeks, when all symptoms subsided. *Mistura assafoetida*, however, is oftentimes disappointing, even in younger children. My second choice would be tincture of belladonna exhibited in 1-drop dose for every month of the child's life, rapidly ascending doses until toxic effects are reached, after which gradually increasing the doses as tolerance of the drug seems to be established. In very young children I have obtained good results from the use of a freshly-prepared belladonna-plaster placed between the scapulæ. The physiological action of the drug seems to be more constantly maintained; this may be changed at the end of one week. In a number of very troublesome cases in young children I have gained decided advantage by an application of two-per-cent. cocaine solution directly applied to the naso-pharynx.

This treatment does not preclude the use of hydrogen peroxide, which is continued throughout the catarrhal stage. Bromoform was resorted to in fully twenty per cent. of my cases, and was a keen disappointment; it seemed merely to stupefy the patient and did not apparently shorten the progress of the disease. The coal-tar products pushed to toxic doses modified the cases but slightly. Belladonna and antipyrin in combination gave better results than either alone. Quinine, chloral, creosotum, and carbolic acid I found of but little practical use, owing largely to difficulty in administration. This brief outline of the drug treatment in whooping-cough has reference solely to the catarrhal and paroxysmal stages of the disease. As important adjuncts to the management of the disorder, careful hygiene must be enforced, diet of the simplest character, and a uniformly quiet life. Throughout the whole course of the disease out-door life, so far as possible, should be encouraged, and, if convenient, a sojourn at the sea-shore will shorten the progress of the trouble and limit to a great extent the number of sequelæ.

In conclusion, I wish to invite professional attention to *three* very important factors in the treatment of whooping-cough:

1. The early recognition of the disease before the spasmodic stage, suggested by puffiness under the eyes. Then hydrogen peroxide, or possibly cocaine, applied locally. In very young children the treatment is sometimes abortive.
2. The use of belladonna pushed to toxic effects in the second stage is very valuable.
3. Out-door life, sea-shore the best, if the foregoing are not effective.

*TWO CASES OF TRAUMATIC CATARACT  
IN CHILDREN; EXTRACTION;  
SUCCESSFUL RESULTS.*

BY JAMES MOORES BALL, M.D.,

Professor of Ophthalmology and Otolary in the St. Louis College  
of Physicians and Surgeons; Corresponding Member  
of the Medico-Legal Society of New York.

RECENTLY two cases of traumatic cataract occurring in children have been under my care. Both cases were kindly referred by Dr. W. E. H. Bondurant, of Downing, Mo.

**CASE I.—Traumatic Cataract; Extraction of Lens; Successful Result.**—J. H., boy, aged nine, was struck in the eye by a needle, which pierced the cornea near its centre and entered the lens. Opacity of the lens developed gradually, the lens substance protruding through the puncture into the anterior chamber, forming a rounded mass with a well-defined pedicle. Four days before consulting me inflammation developed; the eye became hard and painful. A careful examination under atropine and oblique illumination showed the condition described above.

Here was a case in which the classical operation for traumatic cataract—viz., linear extraction—was evidently out of place. Much of the lens was not softened; nevertheless, the eye showed increased tension, and this, unless soon relieved, would destroy vision. Since it was evident that the greater portion of the lens could not be removed by the linear method, I immediately made an extraction, passing a Graefe knife at the apparent corneo-scleral junction and severing about two-fifths of the circumference of the cornea. The lens was then extracted through a natural pupil, the eye dressed antiseptically, and the dressing kept constantly moist with a solution of bichloride (1 to 3000). Healing followed rapidly, and at the end of sixteen days the boy's vision in the affected eye equalled  $\frac{1}{10}$ .

**CASE II.—Traumatic Cataract; Extraction; Great Loss of Vitreous; Successful Result.**—A few weeks after the discharge of Case I. another boy, aged eleven, was brought to me with the statement that the thorn from some kind of a "creeper" had injured the eye a few weeks previously. Examination showed a congested conjunctiva, a faint corneal opacity marking the point of injury, dilated vessels in the pericorneal zone, the anterior chamber almost obliterated by the pressure of a swollen lens, and great increase of intraocular tension. The eye had been painful for three days. At the time of the accident and for several weeks following there was no pain.

This was a case for linear extraction, and yet I was sure that much of the lens was still unsoftened and could be removed by the linear operation with great difficulty, if at all. Consequently, I again used a Graefe knife, great care being taken lest the knife pierce the iris and cut out a section of that diaphragm. The section was made as in the previous case, with this difference, that the line of incision was about one millimetre in advance of that in Case I. The greater part of the lens was softened and followed the knife. I was gently pressing with the cataract-spoon opposite the incision and working out some fragments of cortical matter, when suddenly there was a gush of vitreous. Immediately the protruding vitreous was cut off with scissors, only to be followed by more and more vitreous. The speculum was removed, the lids gently but firmly closed, and an antiseptic dressing applied. It was feared that infection might take place, owing to the fact that a large bead of vitreous was necessarily left between the lips of the wound. The following morning the corneal wound was found to be closed, the anterior chamber restored, and the conjunctival cul-de-sac filled with floating beads of vitreous. The pressure had cut off the extra- from the intraocular vitreous. The case progressed favorably, and at the end of the fifteenth day the child's vision equalled  $\frac{1}{10}$ .

*THE DYSPEPSIA OF STRUMOUS CHILDREN AND ITS TREATMENT.*

READ BEFORE THE SECTION OF MEDICINE AT THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, BRISTOL, 1894.

BY W. SOLTAU FENWICK, M.D. (LOND.), M.R.C.P.,  
Assistant Physician to the Evelina Hospital for Sick Children.

DR. T. J. TODD\* was the first to describe the clinical features of a variety of dyspepsia which commonly occurs in strumous subjects, and his observations were fully confirmed shortly afterwards by Sir James Clark.† Of late years the complaint has attracted but little notice, and modern writers are content either to quote the opinions of the last-named observer or to dismiss the subject with the remark that dyspepsia is prone to attack scrofulous children. The complaint is encountered in a modified form in almost every child who presents the general features of the tubercular

\* "Cyclopaedia of Practical Medicine," art. "Indigestion," vol. ii. p. 649, 1833.

† "Pulmonary Consumption," p. 16, 1835.

diathesis, but it is rare for the disorder to prove so severe as to claim the exclusive attention of the medical practitioner. I find that among two thousand cases of disease in children which have come under my care during the past twelve months at the Evelina Hospital, thirty-two were brought to me solely on account of the disease in question, and it is from observations made on these cases that the following remarks have been compiled:

*Sex and Age.*—Girls appear to be more subject to the complaint than boys, for among my thirty-two cases no fewer than twenty-six were of the female sex. The disorder may exhibit itself at any time between the fourth and fourteenth year of life, but it is most common about the age of five.

*Family History.*—In the vast majority of the cases the patient exhibits a strong family tendency to tuberculosis. Thus, in twenty-two instances (sixty-six per cent.) it was found that one of the parents had suffered from phthisis, the father more often than the mother. As a rule, one or more members of the patient's family present evidences of the strumous diathesis. In twelve cases I found that one of the other children was the subject of enlarged cervical glands, or possessed scars or other signs of disease of the lymphatic system or the bones.

*General Appearance.*—The digestive disorder affects all varieties of the so-called scrofulous temperament, but the children who possess the finer and more delicate cast of features prove the most frequent sufferers. In addition to the general appearance indicative of the strumous diathesis, some local manifestation of scrofula is occasionally encountered. Chronic enlargement of the cervical or submaxillary glands was only noticed in two cases, but in three others typical scars were observed. Chronic inflammation with hypertrophy of the tonsils existed in ten, and phlyctenular ulcers of the cornea in five cases, but tubercular disease affecting the long bones or joints was never observed. Otorrhœa was present in six instances, and many of the children suffered from muco-purulent discharges from the vagina or nose, without any obvious disease being detected in these organs. Anæmia was invariably present, and the digestive derangement seldom underwent any decided improvement until the conjunctivæ and the mucous membranes began to regain their normal color.

*Symptoms and Progress.*—Pain in the abdomen constitutes one of the most constant and characteristic features of the disease. It is usually quite sudden in its onset, and is apt to occur at irregular intervals. As a rule, the at-

tack occurs during the early part of the evening or night, but occasionally its advent is postponed until two or three o'clock in the morning. The majority of the cases also suffer from a recurrence of the pain during the course of the day, especially just before breakfast and about noon. In twenty-three, or about sixty-nine per cent., of my cases the ingestion of food was also followed by an attack, and the patient was often obliged to hurry off to the closet, owing to a sudden and urgent call to relieve the bowels.

The umbilical region is the part of the abdomen to which the pain is usually referred, though occasionally other districts are also affected. The symptom partakes of the nature of a twisting or cutting sensation, and it frequently appears to commence a little to the right and above the navel and to proceed transversely across the abdomen from left to right. Occasionally the hypogastrium is the chief seat of the suffering.

The pain may prove severe from the very commencement of the attack, but it generally grows more and more intense until a maximum is attained, after which it gradually declines. Sometimes the expulsion of a large quantity of gas, either by the mouth or the rectum, is followed by more immediate relief. The actual duration of the pain varies from five minutes to several hours. The nocturnal attacks are the most severe and endure the longest; but when the disease is undergoing cure their duration is much curtailed, and the attacks are eventually replaced by momentary twinges.

The affected region of the abdomen is sometimes slightly tender on pressure, but more commonly firm manipulation affords relief, and very often the child will spontaneously press both its fists or even the corner of a chair into the abdomen when the seizure occurs.

There are certain conditions which appear to favor or even excite an attack of this nature. Constipation is a frequent concomitant symptom of the disease, and it is usually noticeable that the pain is aggravated by the presence of an overloaded colon. When the attacks follow the meals, they occur quite irrespective of the quantity of the food nourishment which may have been taken, but warm liquids or spiced foods are more active in the production of the symptom than other varieties.

Exhaustion from want of food and physical and mental fatigue are all potent factors in the causation of the disease.

The condition of the appetite varies considerably. Occasionally the desire for food is insatiable, but more often the appetite is poor

and exceedingly capricious, and the child is apt to develop peculiar distastes for certain articles of food. Meat fat in general is particularly repugnant to many of these patients, and I found that no fewer than eighty-seven per cent. of my cases were unable to eat this substance without experiencing nausea, acidity, vomiting, or suffering from an attack of biliousness. This dislike is sometimes so intense that the mere sight of fat gives rise to a feeling of nausea. Bacon fat, on the contrary, is sometimes eaten with pleasure, and milk, cod-liver oil, and glycerin are easily tolerated. It is also noteworthy that thirty per cent. of the cases of this disorder disliked sugar in any form, and the mother usually stated that saccharine substances made them bilious. In a few instances it was stated that the child was extremely fond of bitter and sour materials, and especially lemons and vinegar.

Thirst usually constitutes a prominent feature of the disorder, and was present in sixty-three per cent. of the cases. The sensation is chiefly complained of at night, and the child will often get out of bed and search for water, and in one instance I was informed that the dirty contents of the hand-basin had been imbibed in the absence of clean water from the room.

*Constipation* was complained of in twenty-two, or sixty-seven per cent. of the entire number. In some cases the torpid action of the bowels had existed throughout life, but, as a rule, this symptom had only shown itself for the first time shortly before the onset of the pain. The stools are pale and fetid, and usually consist of a kind of putty- or mortar-like substance, but occasionally they are hard and knotty, or they present the appearance of slime. On careful examination of the evacuated material, large quantities of undigested food can be discovered, with a remarkable absence of bile pigment, appearances which appear to justify the frequent remark of the nurse to the effect that the food goes through the body unchanged.

In ten cases, or one-third of the entire number, the bowels were stated to be irregular in their action. In many of these it was a constant complaint that as soon as a few mouthfuls had been swallowed the child was attacked with pain in the abdomen and had to hurry off in order to pass a motion. This sequence of events ensued after every meal, and was a cause of great annoyance both to the patient herself and to her parents. The evacuations in these cases are usually semi-solid in character, and frequently give rise to a sensation of heat or scalding at the anus, or tenesmus accom-

panies the act of defecation. Occasionally the abdominal pain subsides without an evacuation of the bowels.

Under ordinary circumstances, nausea and vomiting are seldom complained of, and flatulence and acidity are equally rare.

Although there may be no actual loss of flesh, the child remains thin and anæmic and never seems to gain ground. The skin feels harsh and dry, but profuse perspiration is apt to occur suddenly during the night. The hands and feet are habitually cold and blue in color, and are liable to chilblains. Sleep is much disturbed by dreams, and the child often talks wildly, gesticulates, or grinds the teeth while it dozes. The urine is usually pale in color and may deposit a considerable quantity of phosphates. The tongue is generally clean and of a darker color than normal, but occasionally it appears to be veiled by a coating of thin white fur, through which the papillæ show themselves in the form of vivid red spots.

From time to time the symptoms are apt to be replaced by others arising from an attack of subacute gastritis. When this disorder supervenes, the child usually awakes in the morning with frontal headache and a foul taste in the mouth and complains of severe nausea. The appetite is in abeyance, but there is great thirst. The face appears pale and puffy and there are dark lines under the eyes. The breath smells sour, the dorsum of the tongue being thickly coated, while the tip and edges are bright red. Aphthæ may appear on the gums and palate. The pulse may be quickened and the temperature slightly raised, but the pyrexia is generally insignificant. Retching or vomiting follows every attempt to take food. There may be acidity and flatulence, and diarrhoea is the most common complication. In some cases, however, obstinate constipation is encountered. The quantity of urine is diminished and it deposits amorphous urates.

These catarrhal attacks are apt to occur every few weeks, and usually last four or five days. I have noticed that they are very liable to occur when dry and mild weather has succeeded a spell of dry northeast wind. In a few cases certain articles of diet have appeared to be responsible for the attack, and I have several times heard it stated that a little fat eaten was responsible for the biliousness.

After puberty the various symptoms usually subside, save for occasional attacks of gastric catarrh. In some instances, however, the disease undergoes a slow form of evolution, and the stomach rather than the intestine eventually becomes the seat of the disorder.

*Etiology.*—In the absence of post-mortem evidence it is only possible to offer a general surmise as to the origin of the complaint and its various symptoms. Todd considered that the dyspepsia was caused by a deficient secretion of the bile, whereby the processes of digestion and assimilation of food in the duodenum were permanently hindered. Although there can be no doubt that this explanation is partly correct, since the symptoms indicate a defective biliary secretion, there are reasons for believing that the liver is not alone at fault. The peculiar situation of the abdominal pain and its character suggest that this symptom arises from an irregular and spasmodic contraction of the colon, a supposition which is confirmed by the fact that in many cases the pain is immediately followed and relieved by an evacuation of the bowels. But, unlike ordinary cases of colic, the symptom does not seem to arise from ingestion of irritating material, nor does it depend entirely on an overloaded condition of the colon. On the contrary, it is most readily excited by such conditions as mental and physical exhaustion, which act through the central nervous system, or by a process of reflex irritation, as when food is introduced into an empty stomach. The sudden and violent peristalsis which is induced in these various ways tends to curtail the period of gastric as well as intestinal digestion, and to hurry the food through the bowel before it has had sufficient time to undergo the necessary digestive changes. It is well known that the tubercular diathesis is closely associated with various forms of neurosis, and it is not, therefore, unreasonable to suppose that the subjects of this disorder may occasionally exhibit an extreme irritability of the nervous mechanism of the digestive tract, which will show itself in the form of sudden and painful peristaltic waves. I am therefore inclined to regard the dyspepsia which is prone to attack strumous children as a neurosis of the digestive tract rather than as a functional disorder of the stomach.

*Treatment.*—The predisposition to tuberculosis exhibited by these patients requires special precautions with the view of maintaining the general health. The child must be warmly clad, and exposure to cold and damp always carefully avoided. Wool should always be worn next the skin, even at night, when a flannel suit should take the place of the usual night-dress. Tepid baths of salt water are always useful in maintaining a healthy action of the skin, and regular but not excessive exercise in the open air should be advised.

Sea air is particularly beneficial in the treat-

ment of these cases, and a few months' residence at Margate, Ramsgate, or Dover, or some other health resort on the east or south-east coast, is often followed by marked improvement. The more relaxing atmosphere of the south of England, on the other hand, is seldom suitable for the subjects of this disorder, owing to the tendency to gastric catarrh, or biliousness, which the climate appears to evoke.

The selection of an appropriate dietary seldom presents any difficulty. All articles of food which contain a large percentage of indigestible material should be avoided; hence vegetables should be either avoided or given sparingly. White fish, chicken, and tender meat are to be preferred to the coarser and richer varieties, and all condiments and highly-spiced foods should be forbidden; on account of the excessive peristalsis which their ingestion is liable to evoke.

Milk and cocoa may be given freely, but coffee and strong tea must be prohibited. Alcohol is seldom desirable, and the constant resort to brandy as a means of relieving pain is strongly to be deprecated. When improvement has set in, a little bitter ale or stout at meal-times is often of service, but these beverages seldom agree in the early stages of the complaint. The meals should be taken at regular hours, and it is often wise to give bread and milk, tapioca, gruel, or other light food about half an hour before the child retires for the night.

The most prominent indication for medicinal treatment consists in the regulation of the bowels. Todd recommended small doses of gray powder for this purpose, followed by a mild course of hepatic stimulants, such as rhubarb, taraxacum, and nitrate of potassium. From my own experience I am inclined to regard these remedies as being chiefly of value when the tongue is thickly coated and nausea is a prominent symptom. As a rule, I have found the extract of cascara sagrada far the most reliable drug in the treatment of the constipation, and usually commence by the administration of 10 to 15 minims of the fluid extract along with a drachm of malt extract night and morning. Occasionally small doses of aloin and nux vomica answer well, or some simple laxative, such as senna and sulphur or the compound powder of licorice, may be employed with advantage. Drastic and saline purgatives had better be avoided, since the exhaustion which is apt to follow their administration increases the tendency to attacks of pain.

When the bowels are moved at each meal, sedatives should be employed to remove the extreme irritability of the intestine, and small doses of nepenthe, compound tincture of camphor, or a solution of morphine may be given in combination with carbonate of bismuth or aromatic sulphuric acid. In other cases the compound ipecacuanha powder may be substituted for the sedative draught.

As soon as the bowels have been brought into a satisfactory condition an attempt should be made to improve the quality of the blood, for as long as anæmia exists the disease is seldom amenable to treatment. The tartrate, carbonate, or ammonio-citrate of iron are to be preferred to other preparations, and occasionally the exhibition of the drug in the form of the compound iron mixture of the Pharmacopœia is attended with success. The medicine must be administered after meals, and a few drops of tincture of nux vomica may be added to it after a time, should the appetite remain poor.

Cod-liver oil is seldom of use in the early stages of the disorder, but as soon as the pain has subsided it may be cautiously employed and the dose gradually increased. If the crude oil produces nausea, the malt extract with cod-liver oil is often of extreme value.

When the symptoms of gastric catarrh present themselves in a child, it should remain in-doors and, if necessary, be confined to bed. The diet should consist entirely of milk, milk and soda-water, beef-tea, thin soup, bovril, or beef essence. Small doses of mercury with chalk may be administered every evening for two or three days, followed next morning by some saline purgative. At a later period an alkaline medicine with or without taraxacum or rhubarb may be given once or twice during the twenty-four hours. If the digestion remains feeble after the attack has passed off, the exhibition of the mineral acids is usually of service.

#### ON THE USE OF BELLADONNA IN LAYING IRRITATION AND HEALING CERTAIN SKIN-DISEASES.

A PAPER READ BEFORE THE SECTION OF DERMATOLOGY,  
BRISTOL, ENGLAND, 1894.

BY ELIZA W. DUNBAR, M.D. (ZURICH).

**B**ELLADONNA does not seem to have been much adopted as a specific remedy in skin-diseases. It does not take in this respect, either in general or special practice, a place like arsenic or sulphur. Authorities on therapeutics disregard for the most part any

particular action of the drug in skin-eruptions, and such exceptional notices as may here and there be found touch on its anodyne properties or its being an assistant in securing the action of the intestines, and not at all on its being an agent by which reddening, thickening, and irritation may be subdued. Although bromide of potassium has its place in lists of well-authorized remedies in various skin-complaints, belladonna may be looked for in vain, either in the lists attached to a work so much up to date as "Martindale's Extra Pharmacopœia," or Squire's last edition of the "Companion to the British Pharmacopœia." Even Ringer, to whom Professor Lauder Brunton in his list of remedies attributes a recommendation of belladonna in skin-affections, gives it no place in his own lists of remedies for eczema, prurigo, pruritus, urticaria, or any kind of dermatitis.

The virtues of belladonna in the direction I have indicated became first known to me in the autumn of 1892, in the treatment of a case of dermatitis exfoliativa. The patient was a lady eighty-nine years old. The affection showed itself first in the face and neck, and spread all over the body, and was accompanied by intense and constant itching and by free and flaky desquamation. She had attacks of gout, and, among various remedies tried, a mixture of wine of colchicum and antimonial wine served to render the affection just bearable to the sufferer. Bromide of potassium failed to give any relief to the continuous irritation. Of external applications, starch powder was alone tolerated. As most remedies seemed to irritate rather than alleviate, my *locum tenens* kindly continued my treatment during my holiday absence, and did not change it until a day or two before my return, and not until, all parts of the skin having been invaded, there was none left to attack, and the process had declined everywhere in severity. I found the skin still very imperfectly healed, reddened and infiltrated, and there was much itching, though not quite so constant or severe.

The mixture of bark and arsenic that had been prescribed, and of which two or three doses had been taken, I directed to be continued, with the result that the whole process revived in all its original severity. Then, because belladonna was antagonistic to opium and because opium caused itching, I prescribed tincture of belladonna in 15-minim doses every six, eight, or twelve hours. Relief was almost immediate. The irritation was subdued, the skin began to heal, and in a few days the malady that had lasted nearly two months

had almost disappeared. Such slight relapses of itching as occurred were speedily allayed by the renewal of the remedy. This experience made clear to me what was the curative agent in a very obstinate case of prurigo, which had finally got well by taking a medicine for a cough, of bark, belladonna, and ammonia. I had strangely until then overlooked the belladonna, though I had found in giving bark alone that the prurigo had become worse, and I had returned to the first prescription in its entirety and with satisfactory result.

I have tested the influence of belladonna as occasion offered in such cases as exhibited irritation of the skin,—in all, thirty-five cases that I can remember,—and have found the drug curative or alleviating in thirty cases,—that is, about eighty-five per cent. With a larger number I could not hope for so large a percentage, but I should consider even fifty per cent. good.

It would be tedious to give details of every case, but I will give outlines of the more striking. The first was one of urticaria, recurring very frequently during several years. The affection is well described by the patient herself as red patches mottling the skin of the head and neck in the slighter attacks, and in the more severe form as white spots or wheals on a bright scarlet surface, the eruption of which is preceded by an intense irritation and feeling of fulness and oppression, with intense throbbing in head and neck, the immediate cause—still nearly in the patient's own words—being mental and emotional excitement, hot articles of food, pepper, curry, etc., hot baths, unusual bodily exertion, such as running, tennis-playing, walking up-hill. Half a drachm of tincture of belladonna daily so far relieved the symptoms that in a month a hot bath could be taken without inconvenience; sudden news of anxious import was heard without inducing an attack. After nearly two years' trial of the remedy the patient reported that, without being quite cured, belladonna had greatly diminished the tendency to the affection and had in this measure rendered life more enjoyable. It now requires much longer and harder exertion, much hotter dishes, and much longer use of a hot bath to bring on an attack.

Another case of urticaria in a young lady, showing itself as red spots round a minute, tingling white centre, was at once relieved by taking this drug, although other treatment had proved useless.

Finding it useful in healing a case of eczema due to too much contact with water, I have given it with good effect in other cases; for instance, in the case of a boy ten years old,

who was covered with patches of eczema, the affection having lasted twenty-two weeks. External remedies had been avoided, but the irritation was great, preventing sleep. After four days of treatment, during which an ounce of belladonna tincture was used and boric ointment applied, a marked improvement had taken place. To test whether the external application or the belladonna was the healing agent, the latter was discontinued, with the result that the affection became worse, subsiding again on the resumption of internal treatment.

In the eczema of children the drug has seemed to me to be much more useful than arsenic in such cases as I have tried it.

Eczema of the scalp and neck in a woman aged sixty was at once improved and healed under the use of belladonna, and another case of eczema, which had persisted on the lips for a whole year, healed by the same treatment.

Combined with *tr. ferri chloridi*, belladonna is successful in relieving pruritus pudendi, and in general pruritus, both in the young and in adults; a lotion of atropine sulphate, half a grain to the ounce, is for the localized affection of great use, even in cases of long standing. A very bad case of prurigo in a child, though it was not cured, was much relieved by belladonna. Of my five unsuccessful cases, one was a very old case of pruritus vulvæ and two of general pruritus, which, although not relieved by belladonna, were cured by potassium bromide. The other two unsuccessful cases were of erysipelatoid erythema of the face.

The dose should be in all cases moderate; restriction, not inhibition, of the activity of the sweat-glands, the possible constriction of the arterioles (an overdose dilates these), and a moderate anodyne effect on the sensory nerves should be aimed at.

Persons are very variously susceptible to the drug, and while some require as much as 60 minims in twenty-four hours to produce the desired effect, most require not more than 45, or even 30, minims daily. Persons who flush and get headache from the smallest doses will derive no benefit from the drug.

It is necessary, before registering a failure in any case, to ascertain that the preparation used is active. Once I found that a patient who had been progressing favorably ceased to improve, and inquiry showed that the prescription had been made up by a different chemist. The medicine obtained from a third reliable house, however, was promptly efficacious.

The good effects show themselves promptly if the dose is the right one, but nevertheless the remedy must be persistently continued until

cure is effected. I have never seen a case that was not promptly improved yield, however persistent the treatment.

# INTRODUCTION TO A DISCUSSION ON THE MANAGEMENT OF ECZEMA.

READ BEFORE THE SECTION OF DERMATOLOGY AT THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, BRISTOL, 1894.

BY MALCOLM MORRIS, F.R.C.S. (EDIN.),  
Surgeon to the Skin Department, St. Mary's Hospital, and  
Lecturer on Dermatology in the Medical School.

## [ABSTRACT.]

IN opening a discussion on this subject, Mr. Malcolm Morris said opinions still differed as to whether eczema were constitutional or local in origin. His own view was that, although a constitutional dyscrasia, such as gout, glycosuria, kidney-disease, rheumatism, or scrofula, might have a serious modifying influence on the local process, the *causa causans* was, in the majority of cases, the action of micro-organisms. He was also of opinion that seborrhoea often prepared the way for eczema by making the skin vulnerable by microbes. He thought, however, that Unna went too far when he taught that eczema was always and in all cases the result of microbic action. He (the speaker) had often seen the disease arise on perfectly healthy skin, apparently as the result of nervous disturbance. Even in these cases he thought it probable that the parasitic factor played a leading part in the process, the inhibition of trophic influence in certain parts of the skin creating weak points, through which microbic invasion could take place. The management of eczema must in every case be carefully adapted to the special indications present. Mr. Morris assumed that eczematous lesions should in all cases be cured as rapidly and as thoroughly as possible, without fear of the "depraved humors" "settling on" the lungs or other internal organs. Of the numerous cases he has treated, in not one has he seen the slightest ill effect follow the cure of eczematous lesions. He suggested the following points for special discussion:

1. Are internal remedies required in eczema? If they are, what are the precise indications which should guide us in the use of them?
2. The influence of diet in eczema.
3. What are the principles on which the local treatment of eczema should be carried out?
4. How is the tendency to recurrence of eczema in those predisposed to the disease to be overcome? Is there any plan of alternative

treatment by which this result is brought about?

1. With regard to the first of these, Mr. Morris held that, as a general rule, the less internal medication there was in eczema the better. A constitutional dyscrasia underlying the skin-affection must of course be treated on the ordinary principles of medicine. In an ordinary chronic eczema, where there was no reason to suspect any dyscrasia, he trusted entirely to local treatment. Internal remedies should be given in accordance with definite indications. When the lesions were acutely inflammatory he found vinum antimoniale valuable, the indication for the drug being the presence of arterial tension, and depression being a positive contra-indication. If there were a neurotic element in the case, sedatives (opium or, if that disagreed, sulphonal, etc.) and nerve tonics (especially quinine and phosphorus) should be combined with local treatment. Arsenic was unreliable and, if given in inflammatory conditions, did harm instead of good. In like manner iron was contraindicated by acute inflammation. Malnutrition and amæmia should be treated on ordinary principles, and any source of peripheral irritation that could be discovered should, if possible, be removed.

2. With regard to diet, Mr. Morris believed that it had no influence at all except indirectly, by intensifying constitutional conditions, such as gout or glycosuria, or by disordering the digestion and causing vaso-motor disturbance. Apart from these indications, he had seen no reason to believe that restrictions had any good effect in eczema.

3. As regards local treatment, speaking generally, he treated every case as if it were of parasitic origin. He began with a very weak parasiticide and felt his way to the use of stronger applications, taking care not to set up any irritation. The best remedy for local use in dry chronic eczema, especially of seborrhoeic origin, was, in his experience, sulphur, and next to that he placed resorcin. These drugs had the special advantage that they not only destroyed the micro-organisms on the surface, but caused exfoliation of the horny layer, and so brought away the microbes which had penetrated to the deeper parts of the epidermis. When the inflammation was acute, ichthyol was particularly useful. Other antiparasitic remedies useful in eczema were salicylic acid, white precipitate, boracic and carbolic acids. For very persistent chronic eczema of the flexures, chrysarobin was of service.

4. As regards the fourth point, change of climate, with complete rest of mind and body,

was often useful. The particular climate suitable in different cases was largely a matter of idiosyncrasy. Spas were beneficial chiefly in obstinate chronic cases. On the whole, the sulphur springs, especially those of Harrogate and Strathpeffer, were the best for external use. The internal use of sulphur waters was particularly indicated when gout or rheumatism underlay the skin-affection. Chalybeate and arsenical waters were useful in cases in which general tonics were indicated. The alkaline waters of Vichy and Ems did not seem to be of any particular use, even in gouty subjects. In many cases the waters of Bath did good.

*THE TREATMENT OF CHRONIC HEART-DISEASE BY BATHS AND GYMNASISTICS AS CARRIED OUT AT NAUHEIM.*

READ IN THE SECTION OF MEDICINE, BRISTOL, 1894.

By F. J. WETHERED, M.D., M.R.C.P.

[ABSTRACT.]

IN this country Nauheim is practically unknown, but the estimation in which it is held in Germany may be gauged by the fact that during the season no fewer than fifteen hundred baths daily are given. Dr. Wethered spoke of the treatment there applied to cases of chronic heart-disease, from actual observations made on the occasion of a recent visit to that watering-place. Through favor of Dr. Schott, he was able to investigate the effects of treatment in fifty cases, and besides obtaining their histories from their own mouths, had ample opportunities for observing their physical conditions during his stay at Nauheim.

The treatment both by baths and gymnastics, Dr. Schott assured him, could be very well carried out elsewhere, after the acquisition of a knowledge of the system. Nauheim is situated on the Taunus, and is arrived at by train from Frankfort-on-the-Main in about forty minutes. The season commences in May, lasting until the end of September.

*The Baths.*—There are twelve springs at Nauheim, but only four of them are used medicinally. Two are used exclusively for baths, the other two for drinking. Their curative effects were first mentioned by Beneke in 1859, and his observations were extended by the subsequent publication of a monograph in 1872. Others, such as Schott and Groedel, have also written on the same subject.

The chief mineral constituents of the waters are: sodium chloride, 2.8 per cent.; calcium

chloride, two per cent.; and traces of iron, manganese, strontium, etc. There is also much carbonic acid, both free and in the combined state. In one spring there are no less than 889 cubic centimetres in 1000 grammes, and in another as much as 1066 cubic centimetres per 1000 grammes.

*Use of the Baths.*—They are used in the following order:

1. Warm brine baths, without carbonic acid.
- 1a. Warm brine baths, with mother liquor added from the neighboring salt-works.
2. Warm brine baths, with a little carbonic acid.
3. Brine baths, the water being allowed to run in during immersion.
4. Effervescing baths.
5. Effervescing running baths.

Bath No. 1 has a temperature of about 95° F., and is used in cases of great cardiac weakness, the immersion at the commencement lasting about eight minutes. A bath is given on each of three successive days, then suspended for a day, after which more baths are given in a similar manner. After a little while Bath 1a is substituted.

Bath 2 has a temperature of 89° to 92° F. The immersion lasts from ten to twenty minutes. At the commencement some oppression is felt at the epigastrium, but this passes off after a bath or so. On the healthy heart a reduction of pulse-rate is noted, its volume being markedly increased. In the case of a diseased heart the rate is also decreased, and irregularity, if present, disappears, the pulse improving in volume. The respiration is rendered slower and deeper, and there is great relief to the subjective symptoms. The improvement here mentioned lasts at first from one to three hours, the time increasing as the patient has been longer under treatment. As an instance of the effect, Dr. Wethered then gave brief notes of a case observed by himself.

The effervescing bath has a temperature between 88.3° and 91.4° F. Its effect on the pulse is more marked, but of the same character. The sense of oppression experienced during immersion is also greater, but no fatigue is felt afterwards.

In the case of the "stream baths" the pulse-rate is slightly raised, but at the same time the strength and volume of the wave is very markedly increased; this effect lasts for about three hours. Dr. Schott considers that the action of the baths is to be explained by supposing that a reflex action, starting in the superficial sensory nerves and passing through the vagus to the heart, is set up. This view has some sup-

port in the fact that on emerging from the bath the skin is quite red and hot.

*The Gymnastics.*—Although the systems devised by Oertel and by Zander are both well known here, they are but seldom employed. The actual methods made use of at Nauheim should be called "movements with resistance" rather than true gymnastics. These consist of extension, flexion, and rotation of the legs, arms, and trunk, against the carefully-applied resistance of a skilled attendant. Care is taken that no one exercise is repeated twice in succession, and the resistance is very carefully graduated according to indications afforded by the patient himself. Any sign of breathlessness is a signal for its immediate reduction.

Another form of gymnastics is the "self-resisting" movements, in which the action of one set of muscles is resisted by that of the opposite set of muscles in the same limb. Such exercises are either used independently or in combination with the bath treatment.

*Effect.*—The pulse becomes more regular, its volume increasing and its rate diminishing. Any increase in the pulse-rate during treatment indicates too rapid movements, which are then immediately slowed down. Another curious phenomenon is also seen as the result of the exercises,—the area of cardiac dullness becomes greatly diminished. After a course of such treatment, moderate hill-climbing may be recommended.

Dr. Schott also considers that the effect of the "gymnastics" is of a reflex nature.

As for the class of cases suitable for the Nauheim treatment, it may be said that all cases, save those of aneurism, or those with indications of advanced arterio-capillary fibrosis with high arterial tension, may expect to be benefited.

The patients whom Dr. Wethered found there stated that they never derived such great benefit from any other treatment or *régime*, and many of them returned on each successive season. In the severest cases the breathing was soon rendered easier, while ascites and cedema were often so far improved as to admit of carriage exercise or even moderate walking exercise. As to the cases which show the most marked improvement, these are instances of dilated heart, the result of structural alteration, and indications of a failing left ventricle. When there is much severe pain of a pseudo-anginal nature, this rapidly disappears in most instances, under the exercises alone. Cases of valvular disease also do well, if not too far advanced.

Since returning to London, Dr. Wethered has instituted a kind of artificial Bad-Nauheim

at the Middlesex Hospital, and several patients who have undergone treatment under these conditions have already shown great improvement.

### AN ADDRESS ON PYREXIA AND ITS TREATMENT.

DELIVERED IN THE SECTION OF MEDICINE AT THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, BRISTOL, 1894.

BY W. HALE WHITE, M.D., F.R.C.P.,  
Physician to Guy's Hospital.

[ABSTRACT.]

AN animal is said to be suffering from pyrexia when its temperature exceeds the limit of health. In man this limit is between 98° and 99° F., but its extent varies in different animals. In cold-blooded animals it is very great, and the evolution of warm-blooded from cold-blooded animals is to be attributed to the fact that the former are primarily aquatic, while the latter are primarily terrestrial.

Heat is produced for the most part in the muscles, and is under the control of the central nervous system. Experiments show that damage to the corpus striatum produces a great rise of temperature. Heat is lost by the skin and lungs, and the loss, too, is under the control of the central nervous system. Some have supposed that there is a regulatory mechanism which is constantly so adjusting the loss and production as to keep the temperature constant, and that the pyrexia which follows on damage to the cortex is due to interference with a thermotaxic mechanism situated there. Others regard this form of pyrexia as due to the fact that the cortex has thermogenetic functions as well as the corpus striatum. The high specific heat of animal tissues is of great help in maintaining the temperature constant. All these parts of the central nervous system may be influenced reflexly from the periphery and directly by the composition of the blood circulating through them, so that we have a central nervous temperature due to lesions of the cortex, the corpus striatum, the crura, pons, and cord, and a reflex pyrexia and a circulatory pyrexia.

We will now consider each of these clinically.

#### CENTRAL NERVOUS SYSTEM.

*Cortex.*—The author has collected fifty cases in which damage to the cortex in man had caused a rise of temperature, sometimes as high as 109° F., and when the cortex was damaged on one side only the temperature would be found to be highest in the opposite axilla. In men-

ingitis also perhaps the great height of the temperature was in part due to the irritation of the cortex. Many functional disorders in which the functions of the cortex were perverted showed pyrexia. Such were epilepsy, delirium tremens, and chorea, but the most important was hysteria. The chief characteristics of hysterical temperatures were the age, sex, and hysterical character of the subject, the fact that it is very erratic, that it may vary in different parts of the body at the same time, that pulse and respiration ratio to the temperature is often irregular, that other signs of fever are often absent, and that the action of antipyretics is often uncertain. Allied to these hysterical temperatures we have the so-called inexplicable pyrexia, which may continue for months, usually with a swinging temperature every day. The explanation of these is very doubtful.

*Corpus Striatum.*—Many instances of pyrexia due to damage of this were quoted, and it was pointed out that a rise of temperature could usually be detected in hemorrhage into the corpus striatum. In the first few hours there might be a fall due to shock, but soon it begins to rise, and attains its maximum—often as great as 105° F.—in four hours. Then for four days it gradually falls, and reaches normal on the fourth day. For the next four days it usually is subnormal, after which it is normal. Up to this time it is always higher in the axilla opposite to the lesion than in that of the same side.

*Crus, Pons, and Cord.*—Cases of temperature due to damage of these parts were given, and it was therefore concluded that damage of similar parts of the central nervous system, both clinically and experimentally, caused pyrexia. The importance of damage to the central nervous system as a cause of pyrexia was not recognized enough. Dr. Bryant had found that out of one hundred cases of hyperpyrexia, eleven were due to injury to the brain, three to cerebral hemorrhage, six to injury of the cord, and one to myelitis.

*Reflex Pyrexia.*—As an instance of this the following examples were quoted. Surgeons had shown that seventy-five per cent. of the cases of simple fracture had a slight rise of temperature after the accident. Pyrexia was well known to be associated with renal and biliary colic, and Dr. Bryant had recorded six cases of burns, in all of which there was hyperpyrexia, without any evidence, even post-mortem, of septicæmia. Possibly in many abscesses part of the pyrexia was due to the peripheral irritation of the abscess, for, other things being equal, the greater the tension of the abscess the higher the temperature.

*Circulatory Pyrexia.*—Many vegetable poisons would produce pyrexia, such as atropine, cocaine, and caffeine; also animal poisons, as bad meat, mussels, bad cheese, etc., tuberculin, pepsin, and albumoses, would cause pyrexia. The chemical products of excessive muscular exercise would sometimes produce pyrexia, as seen in fatigue fever. In the case of diphtheria and anthrax, two distinct toxins manufactured by the respective bacilli had been isolated, are pyrogenic, and another which produced the other symptoms, and no doubt in the case of all the specific fevers the pyrexia was due to the circulation in the blood of pyrogenic toxins.

#### TREATMENT.

*Hyperpyrexia.*—Although it may be open to discussion whether it is the hyperpyrexia which is harmful, or whether it is that the excessive temperature is merely indicative of some deeper-seated harmful process, the fact remains that the physician knows that if hyperpyrexia is present, the patient is in the very greatest danger. The only treatment possible is the prompt and thorough application of the cold bath. The water should be at a temperature of 75° F. The patient should be kept in till his rectal temperature has fallen to 101° F., which usually occurs in about ten minutes. The bath should be repeated whenever the temperature is obviously rising rapidly. The importance of this treatment is shown by the fact that among fifty-six cases of rheumatic hyperpyrexia, of seven not treated, all died; of three treated by antipyretic drugs, all died; but thirty-three of those treated by cold bath recovered.

*Pyrexia.*—We must remember that it has never been shown that ordinary pyrexia is usually harmful, and also that we are only treating a symptom, just the same as when antimony and aconite were given to reduce the pulse in fever we were only treating a symptom. Now, we believe such treatment to have been unwise, and when we bear in mind how little we know about the cause of fever, there is no *a priori* evidence that the treatment of pyrexia as such may not also be unwise. Such authorities as Cantani, indeed, look upon pyrexia as beneficial. He thinks that it aids phagocytosis and exerts a kind of sterilizing action in the body. Last year, too, at Newcastle, Professor Roy pointed out that pyrexia was one of the defensive mechanisms which we possess against the organisms of the specific fevers, and Sana-relli holds the same opinion. But even if pyrexia does no good, that is no reason why we

should treat it, for it may do neither good nor harm. The remedy may be worse than the disease. Then, too, the treatment of single symptoms is bad for the doctor. It gets him into bad habits, and therefore in the long run it is bad for the patient. Also the treatment of pyrexia gives a false sense of security, for we have seen that some of the specific micro-organisms manufacture two toxins,—one pyrogenous and the other inducing other symptoms. By treating the pyrexia we leave the other toxin free to do harm, although, because the temperature is lowered, we fancy that the patient is better. Then, too, the reduction of the temperature abolishes a very valuable help to diagnosis. Especially do we miss this in the cases of deep-seated abdominal suppuration or those of doubtful specific fevers. The reduction of pyrexia may, too, impair immunity, for we know that the conferring of immunity often entails pyrexia; and, lastly, it must be remembered that antipyrin, antifebrin, and phenacetin are in large doses severe poisons. As, therefore, it is doubtful whether the treatment of pyrexia as such is a good thing, we must examine those diseases in which the use of antipyretics undoubtedly does good. Such are ague, rheumatic fever, and typhoid. Now, in ague quinine does not act as an antipyretic, but as a direct poison to the plasmodium malariae, and it is highly probable that in rheumatic fever salicylates also act as direct specific remedies. With regard to typhoid fever, there is no doubt that if large numbers of cases are taken, those treated by the external application of cold do better than those not so treated; but, on the other hand, this treatment is not required for all cases. It is not often required if the temperature is below 103° F. No fixed point should, however, be taken; each case must be judged on its own merits, and no physician should slavishly follow one method. What is a good treatment for one case is unsuitable treatment for another. A great point, however, to bear in mind is, that it has never been shown that this treatment acts for good solely because it reduces temperature. It does more than this; it calms delirium, quiets the tremor, lessens the prostration, and diminishes the liability to complications, and also it has been stated that during the treatment of typhoid by cold baths the elimination of toxins is enormously increased; therefore it is probable that the cold bath should not be looked upon as an antipyretic any more than as an antideliriant, but that it should be regarded as acting directly or indirectly upon the specific cause of typhoid fever. Dr. Hale White summed up by saying

that hyperpyrexia must undoubtedly be treated by cold baths. The routine treatment of pyrexia is bad, and when the treatment appears to do good it is because the means employed attacks the cause of the disease, and the means is not acting as an antipyretic, or, at any rate, only in the sense in which mercury is the antipyretic of syphilitic fever. Antipyrin, antifebrin, and phenacetin should rarely be employed as antipyretics.

#### ON THE TREATMENT OF NEURASTHENIA.

READ BEFORE THE SECTION OF PSYCHOLOGY AT THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, BRISTOL, 1894.

BY G. H. SAVAGE, M.D., F.R.C.P.,  
Lecturer on Mental Diseases at Guy's Hospital.

#### [ABSTRACT.]

THE author stated his views as to the nature of neurasthenia, which had been defined as a nervous disorder in which there were weakness and irritability of the nervous system. The greater number of the patients suffering in this respect did not, however, become insane. Nervous weakness might be accepted as another name for the disorder, but he was unwilling to consider "brain fatigue" as a synonymous term. Omitting the theoretical and etiological portions of the discourse, the following were the hints offered by the author as to the proper treatment of the affection:

The first consideration is, that assertion rather than argument with a patient is always to be counselled. Let the physician lay down the regulations and then decline to discuss them. In laying down a plan of treatment, one of two courses is to be adopted,—either isolate the patient, so as to give complete rest, while means are applied for the re-establishment of the nervous system, or place him under firm, skilled companionship, and make him help to work out his own cure by indulgence in muscular exercise, etc. Of course every case must be made a matter for separate study, but in the author's opinion rest is the most important element of success, dieting coming second.

With regard to diet, in some cases it will be found desirable to reduce the daily allowance of meat and to treat the patient as if he were gouty. In others, however, a full, rich diet is indicated. In the case of teetotalers perhaps the best thing is to give a wineglassful of coca wine with a biscuit a short time before the time for sleep. In other cases a few grains of chloral, sal volatile, or paraldehyde may be necessary in order to secure sleep. The last

is, however, objected to on account of its disagreeable taste. In yet other cases a hot bath shortly before bedtime may prove efficacious. In all cases it is well to avoid the use of morphine, or, if this drug be used at all, it should be given without the knowledge of the patient, owing to the great risk of his acquiring the morphine habit.

Hypochondriasis is very liable to show itself in the neurasthenic, but the type is not of the usual and most objectionable kind, for these people have in general an unbounded faith in their doctor.

In concluding his paper, Dr. Savage presented an epitome of the rules for treatment advocated by Dr. Coles, the American neurologist, who considers that what we should aim at is as follows: Objective and subjective symptoms are to be treated, and the elimination of waste products is to be encouraged through the skin, kidneys, and bowels. This should be done by dieting rather than by purges. Hot-water draughts, mineral waters, hot enemata, abdominal massage, regular habits, and the use of fruit in abundance may all be advisable. Digestive pills of some sort may also be of service. Skimmed milk is one of the most innocent and efficacious means of stimulating the secretion of the kidneys. Many of the sufferers showing evidence of a gouty diathesis, salicylate of sodium should be borne in mind as an efficient means of encouraging the removal of uric acid. The action of the skin may be promoted by moderate exercise short of fatigue, hot bathing at night, or, in some cases, by an occasional Turkish bath. Although sea-bathing is of service in isolated instances, it is not to be advised, save with great circumspection, as in many instances it is apt to cause more harm than good.

With regard to the question of dieting, it should be one's aim to give a good solid diet, but this must be done gradually. Thus, to begin with, a full milk diet is to be ordered, and this is to be gradually supplemented with fish and, after a time, with the more digestible meats. Food should be cooked in the plainest manner possible. Ordinarily it is well to avoid the use of much meat essences, but cream, malt, and prepared foods may be given. Kumiss is one of his favorite food beverages, and digestion may be materially aided in some cases by the administration of small doses of sal volatile a short time after meals. It is, again, of great importance that food should be administered at regular intervals,—generally every four hours. Should the sufferer wake early in the morning, fluid food in some form should be at hand, and

a glass of milk under these circumstances sometimes secures an addition to the hours of sleep. Exercise should not be too prolonged, and should be taken in cheerful companionship. Dr. Savage is a strong believer in the efficacy of golf under these conditions. In the slighter cases a sea-voyage in good company may often effect a complete cure.

As sleeplessness is a typical symptom in most cases of neurasthenia, it is well to know how best to combat it. Hypnotics are to be, as a rule, avoided, but the use of suitable food, stimulants, coca wine, and hot baths are, as already mentioned, of service.

After a hot bath, however, it is important to avoid all mental work, as its beneficial effects are easily overbalanced.

As for the use of electricity in one form or another, the author was not inclined to speak with enthusiasm, and he also regarded hypnotism with disfavor. Subcutaneous injections of serum had been said to yield good results at the hands of some French observers, but of this method of treatment he could not speak from personal experience.

#### *THE EFFECT OF CREOSOTE ON THE VIRULENCE OF THE TUBERCLE-BACILLUS.*

A PAPER READ BEFORE THE SECTION OF MEDICINE AT THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, BRISTOL, 1894.

By W. KINGTON FYFFE, M.B., M.R.C.P.,  
Medical Registrar, St. George's Hospital; Late Pathologist and  
Medical Registrar, Victoria Park Hospital for  
Diseases of the Chest.

#### [ABSTRACT.]

IN this paper an investigation was described upon the effect of creosote when administered (1) simply by inhalation, (2) by the mouth, (3) by means of a chamber filled with the fumes of creosote, in which patients were kept for an hour daily. The method adopted was to inoculate sputum into the legs of guinea-pigs before the patients were put under any treatment, and again at the end of a two months' course of creosote, and the results were compared by the length of time the pig lived in each case and by the condition of the tuberculous mischief in the pig when killed on the fifteenth day. In twelve cases in which patients simply inhaled the drug, though they were taking cod-liver oil and such like drugs in addition, creosote had no effect whatsoever. The lesions in the guinea-pig produced by the sputum before treatment were exactly equiva-

lent to those produced after two months' treatment by inhalations of creosote.

When given by the mouth, even in small doses (2 minims three times a day), there was a distinct effect on the animal injected; the primary inoculation before treatment killed the animal in twenty-one days. The second inoculation, after treatment had gone on for two months, killed the pig at the end of seven weeks. In the case of larger doses (6 minims *ter die*), the primary inoculation killed in twenty days, the second not for nine weeks.

The longest time that any pig lived was three months after inoculation with sputum from a patient who had been taking 10 minims of creosote for two months. Eleven cases in all showed that the larger the doses the longer the animals injected lived. It must be admitted, however, that no matter how large the dose (up to 12 minims three times daily), the pigs eventually died of tuberculosis; so that, though the power of the bacilli was rendered less, the organism was only weakened, not killed. With regard to those cases treated by the creosote chamber, only two were investigated. In both these inoculations at the end of two weeks' treatment did not kill guinea-pigs for fourteen to fifteen weeks. Though the number of cases is too small to draw any definite conclusion from, it is evident that the virulence of the bacillus was markedly affected, and that the animals lived longer than in any of the cases experimented upon. Further experiments were made on tuberculous guinea-pigs. Guinea-pigs were inoculated with tubercular sputum in one leg; into the other creosote was injected, with the result that though the pigs died from cellulitis set up by the creosote, generally about the sixteenth day, tubercle-bacilli were only found at the seat of inoculation, not elsewhere. A control animal killed on the sixteenth day had extensive tuberculosis of its viscera. If, however, the injections of creosote were not begun till fifteen days after the sputum had been injected, they had no effect whatsoever. Injections begun at the end of the first week kept the animal alive for a month.

The conclusions drawn from the experiments were as follows:

1. That creosote given simply by inhalation had no effect on the virulence of the bacilli.
2. That when creosote was given by the mouth, even in small doses, there was a definite effect, and when the dose was pushed there was an extremely marked diminution in virulence.
3. In the first series it was shown that the

animals lived longer than in any of the other cases, but that it is impossible to dogmatize from so small a number.

4. Creosote injected under the skin in tuberculous guinea-pigs, provided that the disease was not too far advanced, had a markedly restraining effect on the ravages of the bacilli.

#### THE USE OF ELASTIC LIGATURES IN LAPAROTOMIES.

Following Professor Olshausen's suggestion, PROFESSOR DOHRU (*Centralblatt für Gynäkologie*, July, 1894) has employed the elastic ligature in about three hundred cases. He uses it in ovariectomies and myotomies, with either intra- or extraperitoneal pedicles.

The ligature is a solid, smooth, four-millimetres-thick strand, which is passed through a lead ring, and the ends being drawn tightly, are held in place by clamping the ring by means of forceps.

This ligature is recommended upon the following grounds:

1. The certainty of blood control. Owing to the strength of the rubber and the ease in securing it, one can apply it tighter than a silk ligature.
2. The ease with which it is rendered aseptic.

Despite the size and the presence of a non-absorbent foreign body in the abdominal cavity, no bad results have followed its use, the ligature being readily encapsulated.

#### ANTRUM ABSCESS.

HERZFELD, in *Langenbeck's Archiv* (*Centralblatt für Chirurgie*, July, 1894) cites four cases of abscess of the antrum of Highmore. Among other symptoms he mentions of diagnostic importance a circumscribed swelling on the septum near the point where this structure approaches the antrum, the mucous membrane of the septum being at this point raised from the bone. While the sounding of the normal opening into the maxillary sinus is often impossible, yet it is possible to break through the anterior wall with a sound or some sharp instrument at a point two-thirds to one centimetre above the lower edge of the middle turbinated bone. After opening, the sinus is washed out with antiseptic solutions, curetting of carious bones and granulations.

THERAPEUTIC GAZETTE with MEDICAL AGE.....	2.50
THERAPEUTIC GAZETTE with WESTERN MEDICAL REPORTER.....	2.50
THERAPEUTIC GAZETTE with BULLETIN OF PHAR- MACY.....	2.50
THERAPEUTIC GAZETTE with AMERICAN LANCET	3.25
THERAPEUTIC GAZETTE with AGE and LANCET...	4.00

Foreign subscriptions may be ordered through our agent in Eng-  
land, Mr. H. K. Lewis, Medical Publisher and Bookseller, 136  
Gower Street, London. Price 10s. Remittances may be made  
either by Postal Order or Stamps.

Price to Foreign Subscribers direct (postage included), \$2.50 (20  
shillings). English postage-stamps received on remittances.

Editorial communications should be addressed 222 South Fifteenth  
Street, Philadelphia. Articles intended for the Original Depart-  
ment of the GAZETTE will be accepted only with the understand-  
ing that they are contributed to it exclusively.

Authors will receive reprints in pamphlet form, without charge,  
provided the request for them be written on the articles sent.

Business communications should be addressed to the Publishers.

## Leading Articles.

### WHAT IS THE SAFE DOSE OF ANTIPYRIN?

WHENEVER a new drug is introduced to the attention of the profession, it goes through a period of experimentation in which even its proper dosage is a matter of doubt. Many of us will remember that when antipyrin was first introduced as an antipyretic, before we recognized its value as an analgesic, the doses generally administered averaged fully 15 or 20 grains. Since that time our increased experience of its action has shown us that much smaller doses are equally efficacious and in the opinion of the majority of the profession more safe. We have already in other editorial articles in the GAZETTE combated to a certain extent statements made by some practitioners that antipyrin is a powerful cardiac depressant, but we have admitted, on the other hand, that there is no doubt that in some cases its employment in very large doses is followed by circulatory depression, particularly in the pres-

ence of severe disease. Our attention has been particularly called to this subject by a case in which very large doses of the drug were administered in the treatment of epilepsy, and also by an article, which will be found in the Progress columns, by Bondurant, which appeared in the *American Journal of Insanity* for July, 1894. In the case of which we speak the heart-sounds were so exceedingly feeble that it was almost impossible to distinguish them, even after exercise. There was marked tendency to vaso-motor relaxation and localized congestion, and there was also some cardiac palpitation. The pulse when the patient was quiet was feeble and irregular. Careful inquiry as to the medication which he had been taking elicited the fact that he had been in the habit of swallowing 50 grains of antipyrin three times a day for eight and a half months. He stated that his tissues bruised easily, small blows making large ecchymoses. He also stated that a well-known member of the profession had recommended these doses, and had declared that they were perfectly safe. In the article of Bondurant, which we have quoted, the average large dose which was administered for many weeks without danger, it is asserted, was from 45 to 75 grains a day, which is about half the amount we have named. Elsewhere we have called attention to the important fact that, after all, the dose of the drug is governed more by the susceptibility of the patient than by the actual number of grains which are administered, and it is also controlled, to a certain extent at least, by the effect which we desire to produce in the disease we are treating. The statistics which have so far been collected regarding the untoward effects of antipyrin indicate that in the majority of instances these untoward effects arose from doses of 10 or 15 grains almost as frequently as with massive quantities, showing, in other words, that susceptibility was a more powerful factor in the production of such symptoms than the actual number of grains. In view of this susceptibility and in view of the uncertainty which to a certain extent exists even at the present day as to the best moderate dose of antipyrin, we may conclude that 5 grains three times a day is quite sufficient as a beginning dose in the vast majority of cases, that in a fair proportion of instances even smaller quantities will be equally beneficial, and that it is exceedingly doubtful whether doses of more than 45 grains a day can be taken without danger to the patient's organism. This is particularly so in view of the fact that the production of chronic poisoning by such doses in the lower animals has been

shown to be followed by slow degenerative changes in the kidneys, liver, and spleen.

#### CONFIRMATORY WORK UPON THE ACTION OF CHLOROFORM.

THE readers of the THERAPEUTIC GAZETTE may recall the results of the study of the action of chloroform carried out under the request of the government of Hyderabad, India, which were published by Hare and Thornton in the October number of the GAZETTE, 1893. The most important contribution to the subject since that time is the article in the *Medical News* of August 25, 1894, by Drs. Randall and Cerna, of Galveston, Texas, who have not only reviewed the literature to a considerable extent, but have gone over the work performed in various investigations with considerable thoroughness. It is interesting and pleasant to note that the conclusions which they arrive at as a direct result of their experiments are practically identical with those which we published in October, 1893, by Hare and Thornton, and this is the more striking because they themselves state that they began their experiments quite convinced that death from chloroform occurred through primary cardiac paralysis, but that their experiments have told quite a different story, so that, to use their own words, "in not a single experiment did we see distinct cardiac failure preceding the stoppage of the respiratory function, and in only one case surely and in a second one probably there was noticed a simultaneous arrest of both respiration and the action of the heart." Their experiments were performed in the presence of a number of the faculty of the Medical Department of the University of Texas, all of whom believed that death from chloroform was due to cardiac failure, but were forced to admit that, in the experiments which they witnessed, a respiratory death took place.

The latter part of the paper of Randall and Cerna consists to a certain extent of a friendly criticism of the final conclusions of Hare and Thornton. It will be remembered that in the work of Hare and Thornton they recognized very distinctly that profound arterial depression associated with cardiac failure, even though death might be *physiologically* due to failure of respiration, was a dangerous and never-to-be-forgotten possibility, and they recommended that the respiration should be watched more than the circulation only, because they believed that the respiration would give the first indication of the dangerous action of chloroform. Randall and Cerna, while agree-

ing in this statement, insist more strenuously than did Hare and Thornton upon the anæsthetizer watching both functions, and we have no doubt that this advice is wise, unless practical experience shows that it is impossible for the anæsthetizer to watch the pulse and respiration and to handle the chloroform satisfactorily at the same time without diminishing his attention to any one of these important duties. It is a fact worthy of note that so competent investigators carrying on independent experiments in the far Southwest should have so entirely confirmed another series of experiments performed on the Atlantic coast under entirely different climatic conditions.

#### THE VALUE OF ARTIFICIAL RESPIRATION IN CEREBRAL COMPRESSION.

IN a communication published in the *Quarterly Medical Journal*, Horsley calls attention to the fact that in cases of cerebral compression, such as arise, for instance, from cerebral hemorrhage, tumor, or depressed fracture, as well as from sudden and violent concussion, especially when applied in the occipital region, death is due to failure of respiration. From experiments on animals he determined that a rise of pressure in the skull always causes slowing and diminution of the respiratory movements and later arrest of the same, and furthermore, after release and re-establishment of the pressure has been carried out once or twice, the respiration becomes periodic, exhibiting the characteristics of Cheyne-Stokes breathing, or simply becomes irregular in force and rhythm. These effects may be due both to direct pressure and secondary anæmia caused thereby.

The three common causes of increased intracranial tension—namely, tumor, hemorrhage, and inflammatory foci—exhibit in their clinical histories sudden death from arrest of respiration, this arrest being invariably fatal, unless the skull is immediately opened and pressure relieved. The truth of this statement Horsley shows by the recital of a number of cases. The most important practical application of Horsley's communication is the accentuation of the value of artificial respiration in cases of compression or of severe concussion. As the author states, when a man drops apparently dead from a blow in the occipital region, death is commonly attributed to heart-failure, and no effort is made to practise artificial respiration, though this is indicated quite as clearly as when death is threatened from drowning. The same holds true in regard to apparent sudden death from

bullet wounds of the cerebral hemispheres, it having been experimentally determined that, provided no interventricular hemorrhage is pressing directly on the respiratory centre, recovery by artificial respiration is possible.

Horsley sums up his communication with the statements that the respiratory centre is more sensitive to mechanical pressure and shocks than any of the lower vital nerve-centres, that where death threatens from intracranial pressure artificial respiration should be performed and the skull opened freely, and in cases of sudden shock artificial respiration should be instituted immediately, and heat should be applied to the head, preferably by irrigation.

The teachings conveyed in this communication are novel and in some respects directly opposed to the common practices advocated in this class of injuries. Thus, the application of hot irrigations to the skull in cases of severe head injury, for the purpose of relieving shock and stimulating the respiratory centre, is directly opposed to the popular practice in such cases. The value of the ice-cap, for instance, is firmly engrafted upon the mind of all hospital surgeons. Immediate trephining in all cases of compression greatly enlarges the field of usefulness of the emergency surgeon; and since it has been shown that life can be maintained by artificial respiration in these cases, he will not have before him the fear of death on the table, an accident which is by no means rare in brain surgery. To those who render first helps to the injured there is now given one more indication for the performance of artificial respiration.

#### *TETANUS ANTITOXINE.*

IN previous numbers of the THERAPEUTIC GAZETTE, both in the Editorial pages and the Progress columns, the interesting experiments of Tizzoni and Cattani in the preparation and practical application of the tetanus antitoxine have been fully detailed. It was stated that this method of treatment must still be considered in its experimental stage, since it has not yet been tried on a sufficient number of human beings to warrant any conclusion as to its efficiency. Each carefully reported case of its use is, however, of great importance, and Giusti and Bonaiuti have just added a new case, which to them is so convincing that they strongly advise the equipment of every railroad medical chest with a sufficient quantity of antitoxine, which should

be immediately injected into all patients whose wounds have been contaminated with earth or dust, thus, as they claim, positively preventing subsequent development of lockjaw. The case in point has been reported with an attention to detail worthy of the most modern scientists.

The patient sustained a lacerated wound of the scalp and face, which was contaminated by earth. The right leg was also broken. The wound was immediately disinfected as thoroughly as possible with carbolic and bichloride solution and dressed with iodoform and carbolized gauze; this process of cleaning was again repeated in a few hours. Twenty-one days later twitchings were noticed about the seat of fracture. In twenty-four hours the symptoms had advanced so that there were tonic contractures of the arms, slight trismus, fixation of the head on extension, pain in the chest, nausea, and vomiting, increased by taking nourishment; shortly true tetanic convulsions developed. The ordinary treatment was continued for three days, the symptoms steadily growing worse. The pulse was running about 140 between paroxysms, and respirations were irregular; therefore, 40 cubic centimetres of serum from an immunized horse, representing a strength of 1 to 10,000,000, were injected; five hours later 20 cubic centimetres were injected. Following this second dose there was distinct amelioration of symptoms in one or two hours. The next day, the condition of the patient not being materially improved, 20 cubic centimetres of dog serum, representing a strength of 1 to 5,000,000, were injected. Seven hours later 10 more cubic centimetres were employed. The following day all his symptoms were very much better; nevertheless, 10 more cubic centimetres of blood-serum and 50 grammes of dried precipitate of horse serum were injected. Following this treatment by some hours violent convulsions were noted. These subsided, and thereafter the convalescence was practically uninterrupted. During convalescence several injections of antitoxine were made.

In considering this case it should be noted that the period of incubation was long,—i.e., twenty-one days,—and even when the disease developed it could scarcely be called fulminant in type; hence it belongs to the class of cases in which under any treatment the prognosis is relatively good. It would appear, then, that the benefit of the antitoxines in this individual case is by no means proved, and that convalescence might have taken place had they been withheld.

It will require many such cases to prove the value of the antitoxine. On the contrary, one

or two instances of tetanus becoming manifest within a few hours or one or two days of the time of wound infliction, and reaching its full development within the day, yet disappearing after injections of antitoxine, will be enough to conclusively prove its value, since under all known treatments the mortality in such cases is almost absolute. Until further proof is adduced, then, the proposition of Giusti and Bonaiuti to make prophylactic injections of immunized serum in every case of earth-infected wound will probably not meet with any very great favor.

### ON THE DISINFECTION OF SCARLET FEVER PATIENTS BEFORE THE COMPLETION OF DESQUA- MATION.

GIBSON writes on this subject in the *Practitioner* for July, 1894. He believes it to be the received opinion in regard to scarlet fever that until desquamation ceases contagion is still present. From the long period this process occupies in many cases, and the inconvenience and irksome toil and trouble therefrom arising to families in private practice, the author was led to investigate the correctness of the common opinion, and to ascertain whether or not sufferers from this disease might not by some method of cleansing or disinfecting be freed from the contagion before the process of desquamation was completed. In every case he has found the means used successful.

The method adopted is simple enough. It is to give a succession of three or four (generally not more than three) comfortably warm baths, sometimes daily, at other times on alternate days, using freely carbolic acid soap, and washing the patient most thoroughly from top to toe. After each bath, except the last, the patient was put back to the bed on which he had lain with the disease; after the last he was taken from the bath into a clean room, there dressed with clothes free from infection, and then allowed to mix with the rest of the family. Any patient with a complication, such as otitis or ulcerated or suppurating throat, was not subjected to the process.

The first case in which he tried the experiment was that of his own son, who had caught the disease at school, about eighteen years ago. The case was of the ordinary kind, but for ten days the fever ran high and the eruption was copious. He was isolated with every practica-

ble precaution in his father's house. All the other members of the household remained at home. About the end of the third week he was fairly well, and was then subjected to the process of cleansing or disinfecting described, and after the third bath was allowed to mix with the other members of the household, consisting of eleven individuals, six of whom were children, and none of whom had ever had the disease. The result was that not one took it. In his case desquamation went on for three weeks after he was allowed to associate with the others. Since then the writer has frequently made similar experiments, and with like results.

The circumstances in different cases varied, in so far that in some the other children of the family in which the disease had broken out were removed, and were brought back as soon as the infected member and the house were cleansed and disinfected. In other cases where the house was large enough, and where isolation could be fairly well maintained, the other children remained. In some other instances, again, the infected member was removed and brought back to mix with the others as soon as he was cleansed or disinfected.

In none of the cases experimented on was desquamation over when the disinfecting process was applied, and the writer had an opportunity of observing its continuance in a number of cases after disinfection had been effected. In several cases desquamation went on for weeks afterwards. Whatever, therefore, be the connection between desquamation and the infectious micro-organism, the union is not so intimate but that the latter may be destroyed or rendered innocuous by a simple process of cleansing after the second or third week of the disease. Desquamation may then be allowed to continue its course to its natural termination without risk of spreading the disease.

In no case did any complication follow the cleansing process; indeed, in all the cases convalescence seemed to me to be rather hastened than retarded. In all the cases every effort was made to keep the patients in bed until disinfection was accomplished. In most cases anointing the body twice daily with olive oil mixed with some disinfectant was employed. The length of the period from the commencement of the disease until the disinfecting process was begun varied slightly, according to the health of the patient. In some cases it was begun immediately after the second week; in others it came at the end of the third week.

The use of the bath as a means of treatment in scarlet fever has been recommended and practised often enough; but it has not been

stated, at least to the writer's knowledge, that the application of bathing with a disinfectant might destroy the contagious principle or render it innocuous at such an early period of the disease as between the second and third week, and before desquamation was completed, or that after the application of it in the manner described patients might be at liberty, even though the process of desquamation was still progressing, to mix with the healthy without risk of spreading the disease.

Should this simple process of cleansing or disinfecting scarlet fever patients so early in the course of the disease, or as soon as convalescence is established, prove generally successful, the advantage to private families would be very great. The maintenance of isolation and other prophylactic means in private houses for four to six weeks, when the patient to all appearance is fairly well, is often effected only at great inconvenience, and is a trying hardship to patient and relatives. If the period could with safety be reduced to two or three weeks without risk of communicating the disease, even though desquamation was going on, the relief to all concerned would be correspondingly great.

#### CHLORALOSE.

FLEMMING, in the *Practitioner* for July, 1894, thinks that we may expect benefit from chloralose in all forms of functional sleeplessness, in the insomnia of psychical excitement, of hysteria, of neurasthenia and overwork, of functional cardiac irritability, and in attacks of epilepsy and somnambulism.

Secondarily, its use may enable us to separate objective from subjective pain, and so help, for instance, in the differential diagnosis of some forms of hysteria.

Chloralose will avail nothing in the insomnia of alcoholic excitement, multiple neuritis, or cerebral hemorrhage, or the sleeplessness due to any painful organic lesion or peripheral irritation.

In the insomnia of lunatics, where there is depression, it is said to be useful if given in large doses.

In the early stages of Bright's disease, chloral hydrate, owing to its effect on the blood-pressure, is probably more efficient.

The author has tried to mark plainly the limits to the use of this hypnotic, to save it, if possible, from the worst curse of a new drug,—that of becoming a fashionable favorite, and, like other fashionable favorites, having to heal all things and all men, with a success that is more

commercially profitable than therapeutically useful.

We probably have in chloralose a practically pure hypnotic,—that is, a drug of which the dose that is sufficient to produce sleep affects the psychical element directly and solely.

#### THE DECOMPOSITION PRODUCTS IN CHLOROFORM.

LOVE, in the *Australian Medical Gazette* for June 15, 1894, after a useful article with the above title, states that we should always keep the chloroform in a cool cupboard and protected from the action of light. Keep the bottle well corked and as full as possible, and never use chloroform obtained from a druggist's, where it is often left exposed to light or heat in ignorance as to the consequences.

#### TROCHES.

CATHELL recommends the following troches in the *Maryland Medical Journal* of August 18, 1894. Of course a thousand and one combinations could be made, but for every-day cases the author has devised the following varieties, and finds them to admirably cover the ground in ordinary practice:

##### MUCO-STIMULANT.

Apomorphine, gr.  $\frac{1}{8}$ ;  
Solid ext. eucalyptus, gr.  $\frac{1}{8}$ .

##### MUCO-SEDATIVE.

Ext. pulsatilla, gr.  $\frac{1}{12}$ ;  
Ergotin, gr.  $\frac{1}{16}$ ;  
Codeina sulph., gr.  $\frac{1}{16}$ ;  
Ext. bellad., gr.  $\frac{1}{16}$ .

##### MUCO-TONIC.

Kalii chlor., gr. i;  
Cubeb,  
Resin,  
Pulv. ipecac,  
Catechu,  
Balsam Tolu, of each, gr.  $\frac{3}{4}$ ;  
Capsici, gr.  $\frac{1}{16}$ .

*Muco-Stimulant.*—The action of these is astringent, stimulant, and antiseptic, and most marked upon the mucous surface, preventing the formation of a thick, tenacious mucus. The writer has, moreover, found them of special advantage in obstinate coughs by promoting marked expectoration and mollifying many bronchial and laryngeal troubles. Again, while they possess valuable stimulating properties, they are free from the extremely bitter taste that characterizes many of the other

troches; in this respect they strongly contrast with catechu, kino, etc., which greatly favors their administration to children and fastidious patients.

*Muco-Sedative.*—This troche sheathes and produces a soothing, calmative effect, lessening the tendency to cough and relieving throat soreness. They have been of marked benefit where the throat and tonsils are acutely inflamed and much swollen. They quickly mitigate irritation, liquefy tenacious mucus and lessen expectoration, and do not constipate. If a patient's cough is severe and irritating, two or three may be allowed in succession. He has used them in the early stages of mercurial salivation with wonderful benefit.

*Muco-Tonic.*—In regard to this troche it may be said with emphasis that no other combination has so many points of merit and is so effective in its action.

The writer has recently added to the original formula a small quantity of capsicum, and finds that the slight glow it produces increases their usefulness. And now, after an extended use of this combination, he finds its value both increased and confirmed. They are admirably adapted for allaying slight irritation of the throat and giving tone and flexibility to the vocal organs.

#### CHLORIDE OF ETHYL AND COCAINE IN MINOR SURGERY.

In the *Australian Medical Gazette* for June 15, 1894, PURSER has tried chloride of ethyl for the avulsion of a toe nail, and it acts splendidly. On many occasions he has seen it used for this with good results, also for cutting down upon needles in the hand and foot when they could be felt, for the removal of small cysts, etc. On two occasions he used it for opening an empyema, with good effect. In neither case was the pus stinking, and both recovered by being treated antiseptically and never being washed out. In both these cases the space between the ribs was ample to admit a good-sized drainage-tube, so that it was not necessary to resect a piece of rib; still, the author believes, had such been necessary, it would have acted just as well. He was first induced to try chloride of ethyl in a lad of fifteen or sixteen years of age. The patient was in a very debilitated condition, and was very nervous about the taking of chloroform, so much so that when the anæsthetist went to the ward to administer it, he was in such a hypersensitive condition that it was not deemed advisable to give it; and it being absolutely necessary

to remove the pus by drainage, the chloride of ethyl was resorted to, with the result mentioned. The other case was that of a man who had a broncho-pneumonia and pleurisy followed by empyema, and he was so enfeebled that he was not considered a fit subject for chloroform or ether. Very little of the drug has to be used, a minute or two sufficing to freeze the part sufficiently. It can be easily applied, and, provided everything is ready for the operation and no delay, the patient will feel nothing. It must be remembered, however, that afterwards, during the thawing of the part, so to speak, the pain felt by the patient may be very acute.

#### SUCCESSFUL FOOD FOR INFANTS.

This preparation is so simple that any one—even an ordinary housemaid—with fair habits of carefulness can make it with ease and certainty. It is prepared thus:

Mix a full teaspoonful of flour and half a cup of cold water; to this add twelve ounces of boiling water and boil for ten minutes in a double boiler. Remove the inner vessel and add to the mixture another twelve ounces of cold water and half a teaspoonful of maltine. Allow it to stand for fifteen minutes in order to let the diastase act upon the starch. Replace the vessel in the boiling water and boil again for fifteen minutes. This mixture, after being strained, should be added to an equal quantity of fresh milk. Naturally, one may change the proportion of milk according to individual cases.

Of ninety cases, seventy-seven were babies between the ages of three weeks and fourteen months. All of them were suffering with characteristic disorders of malnutrition or malassimilation, such as gastritis, enteritis, or both, "idiopathic atrophy," diseases of the skin traceable to visceral lesions, and one case of congested and enlarged liver of five weeks' duration, which became well with no additional treatment than dietary. Of these seventy-seven, sixty-three improved immediately and continued to thrive; thirteen required additional treatment; and one, although fed carefully, showed no improvement. This last child was tried on a wet-nurse and three other foods successively before the proper nourishment was found.

The other thirteen cases were children over fourteen months and under twenty-six months of age. They were suffering from various diseases associated with malassimilation caused by or coincident with the primary disease. All of

them within varying spaces of time took kindly to this food and thrived on it.—OPPENHEIM, in the *New York Medical Journal* for July 21, 1894.

#### SCOPOLAMINE.

HARVEY SMITH writes of the value of scopolamine in the *New York Medical Journal* of July 21, 1894. He says that had it been possible to compare the action of other mydriatics on patients upon whom the scopolamine had been tried, the deductions might have been more absolutely reliable; still, the writer thinks the observations so far made justify us in coming to the following conclusions:

1. That the toxic effect of scopolamine used in one-tenth- and one-fifth-per-cent. solutions is easily produced, but can readily be avoided if the lids be everted or the nasal ducts compressed at the time of instillation.

2. That in diseased conditions of the eye, scopolamine is quite as useful a drug as atropine.

3. That in refraction work complete and thorough paralysis of accommodation with the maximum of mydriasis can be produced in from twenty minutes to half an hour, where the drug is used *coup sur coup*, and that the duration of its effect is from five to eight days.

4. That its greatest value lies in the rapidity of its action, which renders it specially useful for purposes of examination in refraction cases and in diseased conditions of the interior of the eye.

#### THE ANTIPYRETIC TREATMENT OF ACUTE DISEASE.

In the *Practitioner* for July, 1894, RAVEN writes on this topic. He thinks it is not among well-meaning amateurs only that the mania for indiscriminate antipyresis prevails. There seems to be a school, consisting chiefly of very young men, who look upon a rise of temperature as a bad thing *per se*,—as a symptom that must, so far as possible, be put a stop to at once and regardless of any useful purpose that it may serve in the process of a febrile attack,—who, in the presence of pyrexia, resort to antipyretic drugs, to ice, or to cold packs or spongings as naturally as a duck takes to cold water. They would appear to ignore the possibility that a high temperature may be the index of the resistance of the organism to an invading poison, or they would scarcely wish to stop such a beneficent agency. From such practitioners a remark like the following may

commonly be heard: "I found the patient with a temperature of 102° F., so I gave him a dose of antipyrin." With an antipyretic at hand, even diagnosis becomes superfluous.

To exemplify the possible consequences of this kind of practice, take the following case: A child is presented who has a headache, aching limbs, and a high temperature. Nothing sufficiently definite is seen upon which to found a diagnosis, but the presence of the temperature justifies, in the doctor's opinion, the administration of antipyrin or antifebrin, or one of the numerous drugs of the kind that we have at our disposal. In twelve hours' time a white patch has appeared on the child's pharynx, and then resolves itself into one of membranous tonsillitis. Supposing that a depression of temperature has been effected, has it served any useful purpose? Is it not much more probable that it has been harmful? For, tracing the course of such cases, is it not found that a high initial temperature is generally followed by an early crisis and rapid recovery; whereas a much more serious and prolonged, or perhaps fatal, illness is likely to ensue when there is a subfebrile or even a subnormal temperature? It may be inferred that, so far from any beneficial result having been obtained by the dose of antipyrin, the effect has been merely an imitation—fortunately, a weak imitation—of the favorable type of the disease, and possibly an interference with the forces of the system to resist the attack. Again, take measles. Suppose that antipyretic drugs should be given during the period of pyrexia, could any doubt be entertained that the effect might be most prejudicial to the patient? Is not measles, with a sharp temperature accompanying a well-established rash, much more favorable in its immediate and remoter results than measles when the fever is slight and the symptoms but imperfectly developed? Cold bathing was once practised on a large scale during an epidemic of measles; it happened in Fiji. The natives, being attacked, flew into a state of panic and rushed into the sea; the mortality was enormous.

If, then, it be objectionable to treat tonsillitis and measles with antipyretics, the same may hold good with regard to many other acute diseases. These may appear fanciful instances to bring forward, but they are really not so. The young men who, in the author's personal experience, have been addicted to this process of reducing, or attempting to reduce, high temperatures whenever they have been met with, can hardly have excogitated the routine from their own inner consciousness. They must have

been trained somewhere. Undoubtedly we are at bottom empirics, willing to adopt any line of treatment that has been conclusively shown to be useful, though it should be unsupported by, or even opposed to, theory. Thus, no one will question the extreme value of salicylic acid in reducing the pyrexia, relieving the symptoms, and cutting short the progress of acute rheumatism. We do not know whether the salicylates have a direct action on the *materies morbi*, or whether the control of temperature is primarily their beneficial action; but we are content to employ the drug, thankful to have it at our command, and willing to wait until its action can be explained by some philosopher in the future. Again, experience teaches us that the action of quinine in ague is specific, whether in virtue of its antipyretic powers or of some other inherent properties, we do not know. Also in enteric fever, when the pyrexia is dangerously acute, or when it is unduly prolonged, the facts are sufficient to tell us that in antipyresis lies the safety of the patient.

But when an empirical procedure is less satisfactorily supported by facts, theoretical considerations should be allowed their due weight. Of all febrile diseases in which an antipyretic routine has theoretically no place, and practically a very uncertain and unproved one, pneumonia stands prominently forward. Acute pneumonia is defined as a specific fever, running a sharp and short course, characterized earlier or later in its progress by inflammation of more or less lung-tissue and by the presence of a bacterium—Fraenkel's diplococcus—supposed by many to be the *fons et origo mali*. It is believed that the presence of this microbe is the source of the fever and that the febrile action is in itself beneficial,—an agency by which the intruding germs are destroyed by the healthy cells of the body. The lung-substance appears to be the field upon which this battle between the invaders and the defenders is fought out. Pyrexia, then, is the natural result, the degree of which, within due limits, measures the resistance of the organism to the danger by which it is menaced. To attempt the reduction of temperature under such conditions, unless exceptional symptoms declare themselves, appears to be equivalent to ranging one's self on the side of the enemy, instead of joining in the defence. No doubt circumstances may arise under which antipyretic measures may be urgently demanded, as in hyperpyrexia, when the threatened ruin of the cardiac fibre presents an imminent danger, and in those cases when the pyrexia persists beyond the natural term of

the disease the employment of antipyresis may be reasonably considered. As yet no case has been made out for the use of antipyretic measures in ordinary cases of acute pneumonia. Some years ago the writer made a trial of aconite, and for a long time treated every case of acute pneumonia with this: 1 drop of the tincture was given every ten minutes for an hour, and then the same dose was given every hour for four and twenty hours. By this means he succeeded in controlling the temperature, but failed to observe any control of the disease. The application of ice-bags to the chest-wall over the site of the inflamed lung or portion of lung in acute pneumonia is strongly condemned. It is to be assumed that this practice has for its object the direct arrest of the inflammatory process going on in the lung. Now, before considering whether this design is a reasonable or a scientific one, what proof exists that a bag of ice placed in such a position that skin, subcutaneous tissue, bones, muscle, and two surfaces of pleura intervene between it and the lung,—what proof is there that the condition of the lung-substance can be altered by such a procedure? Is it not just as likely that, so far from the blood being diverted from the lung, it is driven into it by the influence of the ice on the surface? And if any advantage should be gained from such applications of ice, would it be certain that this resulted from artificial anæmia of the lung and not from a more copious blood-supply?

But, assuming for the sake of argument that the substance of the lung in acute pneumonia can by this means be subjected to a cooling and depletory process, what would be the beneficial influence over the course of the disease? Would such an effect upon the lung control the pyrexia? The answer to this question would appear to be in the negative, for the pyrexia of acute pneumonia, as has been clearly demonstrated, is not primarily nor mainly dependent upon the local inflammation. The conclusive arguments on this head can be briefly enumerated: 1. The pyrexia is as well marked and often at its highest before—and often long before—any inflammation of the lung exists. 2. Upon the disappearance of the fever, which is often quite sudden, no change is to be traced in the physical condition of the lung. 3. The intensity of the temperature is in no way commensurate with the amount of lung-tissue involved in inflammatory changes; on the contrary, a small area of inflamed lung is attended, as a rule, by a higher temperature than when a whole lobe is consolidated. The reasonable deduction, then, would appear to be that, far

from the inflammation of the lung in acute pneumonia being the cause of the illness, it is, in a manner, analogous to the rashes of the exanthemata, the channel through which the virus is eliminated, or the scene where the invading germs are killed by the defending cells of the organism. In this salutary process there must be inflammation, and woe betide the victims of acute pneumonia who, from old age, intemperance, starvation, or any other source of debility, are unable to offer a good inflammatory resistance to the attack of the malady. Mr. Frederick Treves, in his admirable Lettsomian lectures on peritonitis, puts the following proposition, startling enough to any one, but doubly, trebly startling to the antipyretist: "It may be assumed," says Mr. Treves, "that within a month or so from the disappearance of inflammation from the business of the body, the human race would become extinct." The beneficial effect, then, of subduing inflammation of the lung in acute pneumonia by means of ice-bags, even supposing it possible, appears to be problematical. One thing, however, is not problematical, but certain, and that is, that if ice applied in this way is useful, then the employment of hot poultices must be injurious. You cannot blow hot and cold in this matter. The writer is not prepared to admit that the employment of hot applications for the relief of pain in these cases has any bad effect, and so far, upon the evidence, he is not inclined to relinquish it. It is to be noticed that the preponderance of opinion is that the effect that ice-bags so employed may produce must be attributed to the general lowering of temperature rather than to any impression exercised on the lung itself; and as the general antipyretic treatment of acute pneumonia finds but few supporters, there appears to be no inducement to adopt this ice method on any grounds. Of course there are excellent statistics to support it. All new methods of treatment, however quickly they are exploded, present most encouraging figures. In this matter, however, the statistics are vitiated by the avowal that this line of treatment is not adapted for weakly constitutions. Give any man a series of cases of acute pneumonia occurring in otherwise healthy and strong subjects, and he will show most favorable figures from treatment with peppermint-water.

What the writer has endeavored to convey is not so much objection to antipyresis as to indiscriminate antipyresis; that process of reducing high temperatures, often prior to diagnosis, regardless of their import and their possible utility; of treating a single symptom

instead of regarding its source,—a practice which appears to savor rather of the unspeakable methods of the homœopath than of the science of the physician.

#### TREATMENT OF DELIRIUM TREMENS.

In the *New York Medical Journal* for July 21, 1894, BELLAMY concludes an article as follows:

1. Delirium was controlled with greater rapidity and safety by trional than by other hypnotics.
2. In the majority of cases a marked stimulant effect was observed, possibly on account of the methylic and ethylic elements which enter into the composition of the drug.
3. On account of the low temperature noted in all cases, trional must possess antipyretic properties, thereby simulating its allies of the phenol group.
4. It was always well borne by the stomach, and in one case was rapidly absorbed when administered per rectum.
5. No unpleasant after-effects were observed, and in all cases recovery was speedy, with the exception of two.

#### TREATMENT OF PUERPERAL SEPTICÆMIA.

MADDEN writes for the *Medical Press and Circular* of June 27, 1894, on this subject.

The prophylaxis of puerperal septicæmia largely depends on the sanitation and maintenance of the constitutional condition of our obstetric clients by judicious hygienic and dietetic measures maintained by ferruginous tonics throughout the latter months of pregnancy; secondly, the vital importance of asepsis in everything relating to the patient, her surroundings and her attendants during delivery, and the puerperium cannot be too strongly insisted on. At an early period during labor, and again before its termination, if protracted, as well as after delivery, the vagina should be washed out by warm antiseptic irrigation with either carbolic (1 in 40), boric acid (1 in 25), or lysol (1 in 100) solution. The 1 in 2000 bichloride of mercury solution recommended by some authorities, although a potent germicide, is an unsafe uterine application after delivery, and is here mentioned only to be condemned for that purpose. But for the cleansing of the external genitalia during or after labor, a 1 in 1000 solution of this salt may be employed by means of wood-wool pads, which

should be destroyed immediately after use. The routine practice of merely dipping the hands in an antiseptic solution before touching the lying-in woman is only valuable as an adjunct to absolute cleanliness, and without the latter, as too often employed, utterly delusive as a safeguard against sepsis, and therefore far worse than useless. Such obstetric manual cleanliness as is essential before any vaginal examination or contact with the lying-in or puerperal patient can only be secured by diligent hand-scrubbing with clean hot water and soap, by means of the nail-brush, after which, and not before, the hand may and should be immersed in the antiseptic solution prior to touching the patient.

Thirdly, on the completion of labor, and, above all, more especially whenever that has been tedious, instrumental, difficult, or complicated, the uterine cavity, as well as the vagina, should be thoroughly flushed out with hot boric or carbolic solution, or peroxide of hydrogen. For this purpose the irrigator should invariably be employed, as the ordinary siphon syringe, when misused for uterine injection shortly after delivery, is extremely liable, as exemplified by cases referred to by the writer, to force the injected fluid, or even air, through the Fallopian tubes, giving rise to metro-peritonitis, or into the then patulous uterine sinuses, and may thus possibly occasion death from embolism.

Although the prevention rather than the treatment of puerperal septicæmia is the object to which the obstetrician may most profitably direct his attention, the latter subject cannot be here omitted from consideration, and must be chiefly guided by the special type of the disease, as well as by the predominant symptoms and condition of the patient in each instance. In the now more prevalent typhoid form of puerperal fever, the disease is distinctly of a remittent character, as shown in several clinical charts exhibited. For its treatment, free stimulation, suitable nutrition, and strict asepsis by local irrigation of the urethro-genital tract are essential; while, in the way of medicine, there are only three drugs which appear to the writer as possessing any approach to specific remedial or germicidal action in such cases,—viz., quinine, sulphurous acid, and turpentine.

In all cases of puerperal fever in which the use of rectified spirits of turpentine may be tolerated by the stomach and bowels, the writer believes that no other remedy is of such general utility as this, the efficacy of which (like so many other obstetric ideas the credit

of which has been given to modern foreign authorities) was originally demonstrated in Dublin by a long-forgotten Irish practitioner, Dr. Brennan, upward of eighty years ago. The remedial action of turpentine in appropriate cases of puerperal fever the author has proved, and ascribes to the probable germicidal potency of the drug no less than to the effect of a powerful stimulant. Besides, there are other agents available in accordance with the special symptoms and stage of the disease and condition of the patient in each case, which need not be referred to, as their employment must obviously be directed by the broad principles of general therapeutics. In the earlier stage of puerperal fever no remedy has afforded such advantage in reducing temperature and pulse-rate, unlocking pent-up lochial and mammary secretions, inducing sleep and tranquillizing the patient, as phenazone (antipyrin) in small and repeated doses. The effects thus produced are, however, too frequently but temporary, and in the latter stages of puerperal septicæmia, or where from the first the intensity of the puerperal septicæmic intoxication and consequent prostration are most marked, then, it is almost needless to add, antipyrin is distinctly contra-indicated.

#### *APOCYNUM CANNABINUM IN HEART-DISEASE.*

A. G. GLINSKI (*Vratch*, Nos. 6 and 7, 1894), after having proved by experiments on cold-blooded and warm-blooded animals that the root of the *Apocynum cannabinum* contains a strong poison which in large doses paralyzes the heart, and when given in small quantities retards and strengthens its beats, decided to take it himself, as he is suffering from hypertrophy of the left ventricle, with intercurrent attacks of dilatation of the organ, mitral murmur, dyspnoea, etc. The dose was 15 drops of the fluid extract three times a day. As he found that all his symptoms disappeared in two days, he gave it also to other patients in the same quantity in cases of palpitation, disturbed compensation, in which strophanthus and adonis vernalis had failed and digitalis seemed contraindicated. He gives a full account of some of his cases, and summarizes his experience in the following conclusions:

1. The action of the root of *Apocynum cannabinum* is similar to that of digitalis without being cumulative.
2. In cases of dilatation the fluid extract rapidly diminishes the area of dulness.
3. It increases the daily amount of urine.

stops the palpitation, and promotes the absorption of transudations.

4. With the exception of increased pulsation of the arteries of the head, it has no bad secondary effects. It was used either in the form of a decoction (1 drachm to 8 ounces) three to four tablespoonfuls a day, or tincture (1 in 10) 5 to 10 minims three to four times daily, or fluid extract in doses of 10 minims to  $\frac{1}{2}$  teaspoonful three times daily.—*British Medical Journal*, June 23, 1894.

#### QUININE AMBLYOPIA.

From the study of this subject, CLAIBORNE thinks the following conclusions may be drawn :

1. Quinine in toxic doses may produce blindness.
2. The toxic dose is distinctly indeterminate.
3. The duration of the amaurosis varies largely.
4. The field of vision remains contracted.
5. Central vision usually returns to the normal.
6. There is color-blindness at first ; the color perception is ultimately restored within the central field.
7. The ophthalmoscopic picture is that of white atrophy.
8. Experiments on dogs show that there is atrophy of the entire optic tract.
9. The same experiments show that the cells of the cuneus are probably not affected.
10. Treatment is of no avail.—*New York Medical Journal*, June 30, 1894.

#### TREATMENT OF TYPHOID FEVER.

OSLER ("Johns Hopkins Hospital Reports," vol. iv., No. 1) states that two hundred and twenty-nine cases of typhoid fever have been treated in the hospital. The cases in the first year (thirty-three in number) were treated symptomatically ; they yielded a mortality of 24.2 per cent. The remaining cases were subjected to the cold-bath treatment, and yielded a mortality of 7.1 per cent. The cases in the first year were of unusual severity, but the mortality under the cold-bath treatment was very favorable when compared with the average mortality in hospitals in America, which, according to Osler, ranges from ten to fifteen per cent. A bath at 70° F. was given every third hour, when the temperature taken in the rectum was 102.5° F. or over. If the fever was very slightly

colder (65° F.). The temperature was taken half an hour after the bath, and again three hours after. If then above 102.5° F. the bath is repeated. The frequency of the baths thus depended on the severity of the case ; the average number in the twenty-four hours was four, but the maximum number (eight) was often given. The patient was lifted into the bath covered with a sheet or with a napkin round the loins. Cold effusions to the head during the bath were regarded as important, especially in cases with marked nervous symptoms. A cloth wrung out of ice-water was placed upon the head, and the head and face bathed with a sponge wet with the same water. The trunk and limbs were rubbed during the bath with a cloth or bath-rubber ; this was found to counteract the shivering and tendency to cyanosis. The usual duration of the bath was twenty minutes, but in feeble patients the duration was reduced when there were signs of increasing weakness. Brand's injunction to begin the treatment at the very beginning of the disease could not be carried out in the majority of cases, as only ninety-five cases were admitted in the first week, and most of these at the end of it. Half an hour after the bath the temperature was found to have been lowered from 1° to 3° F., but, as a rule, during the height of the disease, in two hours more the temperature had risen again to its former height. In "not a few cases" the bath at 65° F. had very little influence in reducing the fever, and in none was it found possible to keep a patient afebrile. In some cases, particularly in children, and at a late stage (third week) in adults, the bath at 70° F. brought the temperature down to normal, or to 96° or 95° F. The bath has a tonic effect on the circulatory system, especially in the early stage of the fever ; it seems to be exercised as much on the peripheral arterial system as on the heart. The most striking effects of the bath are on the nervous system : headache is relieved ; the patient sleeps well ; tremor, delirium stupor, and coma are rare. In the series reported only thirteen presented marked nervous symptoms. The dry, brown tongue and gastric irritation are less often seen. Speaking generally, the "typhoid state" is not nearly so frequent under the cold-bath treatment, which appears also to have an influence in diminishing diarrhæa and tympanites. In the series reported, hemorrhage and perforation were more frequent, and relapse more often observed in those treated by the cold-bath treatment, but this may have been accidental, and, as has been stated, the general mortality was much lower. Complica-

tions were rare, with the exception of boils, which were frequent. The baths do not aggravate the preliminary bronchitis and do not induce pneumonia or pleurisy.—*British Medical Journal*, June 23, 1894.

#### TREATMENT OF TRAUMATIC SHOCK.

T. S. K. MORTON writes in the *Polyclinic* of June 30, 1894, on shock. He thinks external applications of heat easily take precedence of all measures for treatment of shock. If the clothing be wet, it should be hastily removed. If not, it may be removed from one part at a time, while to others warmth is continuously applied. The apartment in which the patient lies should be heated to 90° F., or even 100° F., if possible. He should be placed in proximity to fires if impracticable to remove him to more suitable surroundings. Blankets should be heated to a high degree in an oven or otherwise, and be wrapped about each part, while more blankets should be tucked in over all. Hot-water bottles or cans should then be packed in all about, but scrupulous care must be taken that the patient be not burned by them. Burns from this cause are distressingly frequent even in the best-conducted hospitals. The tissues during shock appear to be far less resistant to heat than in health, while the sensations are benumbed; hence very severe burns may result in an incredibly short time from even moderately-heated bottles. An additional safeguard is to wrap each bottle in a separate piece of blanket, and never to permit them to come into immediate contact with the skin. A hot bath, if attainable, is a most efficient means of combating shock. This may be made of 90° F., the patient put in, and then more hot water added until a temperature of 100° to 110° F. is reached. For measuring this a thermometer should be employed. If a water-bed is available, it may be filled with water of 120° F., a light blanket thrown over, and the patient placed upon it. To prevent shock during operations, steam and hot-water operating-tables have been devised.

Rectal injections of water of 110° F. are exceedingly useful. Large amounts of caloric may thus be thrown into contact with the great viscera and abdominal nerve plexus, if the injection is slowly given, and particularly if the rectal tube (inserted beyond the sigmoid flexure of the rectum) is employed.

Very hot drinks are also useful in amounts not exceeding two ounces, frequently repeated if the patient can swallow, but are neither so

efficient in relieving shock and thirst nor in supplying a circulating medium in cases of hemorrhage as are the enemata.

A method of applying hot air to a shocked person, which can readily be adapted and is exceedingly efficient, is to raise the bedclothes by a few barrel-hoops. Then procure a couple of pieces of stove-pipe with a right-angle joint. Insert the horizontal end of the pipe under the bedclothes at the foot of the bed, well above the patient's feet (which otherwise might be burned), and under the vertical end place an alcohol or other lamp. The heated air from the lamp will ascend through the pipe and surround the patient to his neck with a heated atmosphere. A more elegantly constructed appliance of this description has done valiant service in the Polyclinic Hospital.

While heat is being applied, frictions may also be resorted to with good effect. For this a hand is inserted under the snugly tucked in blankets, and one extremity after another is rubbed and kneaded towards the heart. Several persons may be thus employed upon different parts, caution being urged that no cold air meanwhile be admitted under the covers. To make these manipulations more efficient in stimulating the cutaneous circulation, a little table salt, mustard, or turpentine may be rubbed in.

Large mustard-plasters or turpentine stupes placed over chest and abdomen likewise greatly aid in restoring the shocked subject.

Where hemorrhage has been marked, transfusion of hot saline solution (common salt six-tenths per cent. in distilled water, boiled and cooled to 105° F.) is imperatively called for. It may be slowly thrown into a vein to the amount of one to three pints, according to the quantity of blood lost, by a syringe, or from an ordinary sterilized douche-bag and canula. The internal saphena vein as it crosses the internal malleolus is a favorite point for its introduction. This vessel is difficult to locate in a collapsed subject, but may generally be made to stand out sufficiently to be identified by the application of a band or tourniquet loosely to the lower thigh or by depression of the member over the side of the bed. The pulse or heart-action must be the guide for the amount to be injected. Prompt response by that organ is the rule, but if no cardiac response takes place, not more than three pints should be employed at one time; the canula may be left in place, and more solution be used at a later period, if required.

The heart may also be stimulated and the

circulation of the nerve-centres and great viscera be improved by elevation of the lower extremities. We have known success to follow almost complete inversion by tying the feet to the end of the bed, and then raising the foot-board to an almost vertical position. Bandaging all of the extremities has a similar effect. Artificial respiration also is occasionally efficient in prolonging the vital spark until the equilibrium of the nervous and vascular systems is re-established. Electrical stimulation of the heart may be tried.

Operations, transportation, or other manipulations calculated to renew or prolong shock should never, except under the most exceptional circumstances, be undertaken until reaction is fully established and the temperature has reached normal or, better, gone considerably beyond. Violation of this rule is accountable for the terrible mortality of major operations for traumatism in the hands of those doing but occasional surgery.

Food should not be administered until reaction has well advanced (as shown by a temperature rising towards the normal), as digestion is suspended during shock, and prompt vomiting or decomposition would quickly result. It is questionable whether the benefits of irrigation of the stomach with hot water are not counterbalanced by the additional shock induced by the passage of the stomach-tube, unless much food is present and can be removed at the same time. When reaction is almost established (temperature 98° F. and over), hot beef-tea and two-drachm doses of diffusible stimulant, as brandy or whiskey, well diluted, are permissible and efficacious. But for some time after reaction, food must be of the most absorbent character, that it may be handled by the enfeebled digestive organs. Peptones, peptonized milk, beef-tea, and strong coffee, always hot, then become available. These may also be administered by rectum, at intervals of not less than four hours, and considerably diluted. For the latter purpose the following formula is satisfactory: Liquid beef and bread peptonates,  $\frac{1}{2}$  ounce; peptonized milk, 2 ounces; hot water,  $3\frac{1}{2}$  ounces. To this two drachms of stimulant (brandy or whiskey) may be added in addition to the sherry found in most of the liquid peptone preparations on the market, if the rectum proves retentive.

Of the drugs which we have come to rely upon in treating shock, may be mentioned atropine, strychnine, ammonia, digitalis, morphine, oxygen, ether.

If pain is present,  $\frac{1}{4}$  grain of morphine with

$\frac{1}{16}$  grain of atropine, hypodermically, is efficient; the atropine is always called for, with a smaller dose of morphine in cases where pain is not a feature.

Strychnine may be given in  $\frac{1}{16}$ -grain dose by hypodermic in conjunction with the above, and is certainly a powerful stimulant.

Digitalis is used in 10-minim subcutaneous doses, more as the effect of the previously administered drugs begins to pass away, in order to maintain the effect upon the circulation for a prolonged period.

Pure ammonia is very useful as an inhalant, a few drops upon a little absorbent cotton being held to the nostrils for an inspiration or two several times a minute, until other remedies begin to take effect. Oxygen, if at hand, is one of the most powerful, yet safe, remedies that we possess; through a mask or tube the patient is permitted to inhale the pure gas for a half-dozen or more respirations in each minute.

For very quick but transitory effect, a hypodermicful of ether or brandy, or even aromatic spirits of ammonia, is very satisfactory, unless the patient has been under ether anæsthesia. In this case resort should not be had to the two former agents.

It is important in treating shock that too many drugs or too many individual remedies be not employed. Poisoning must frequently take away a last chance from the patient, where repeated doses of powerful medicines are indiscriminately given in the excitement incident to a desperate case. Remedies even here must be used with discretion and doses be graduated by effects.

#### THE NEW TREATMENT OF DIPHTHERIA.

It seems likely that yet a new boon to humanity may ere long be anticipated from recent knowledge gained by experimental research. Sir Henry Roscoe's interesting and able speech at the recent meeting of the National Health Society at Grosvenor House directed public attention to the remarkable results obtained by Ehrlich, Kossel, and Wassermann in the treatment of diphtheria. A full summary of these was given in the *British Medical Journal* of May 5. They deserve to be put to the test in this country as soon as possible. Various investigations have recently been made, especially by Behring and Kitasato, on the antitoxins of tetanus and diphtheria, and they found that a substance was present in the blood-serum of immune animals which had the power of conferring a certain degree of immunity in other animals, and even of arresting the disease when

it had begun. These facts were applied by Tizzoni and Cattani to the treatment of tetanus in man, but with only imperfect results. The authors have followed the same lines in applying the method in the treatment of diphtheria, but they have taken special measures to obtain a particularly powerful antitoxin for the purpose. They began with producing immunity in goats by injecting increasing quantities of boiled cultivations of diphtheria bacilli, and the degree of immunity was subsequently further increased by injecting larger and larger quantities of extremely virulent cultivations of diphtheria bacilli. The serum of these animals thus contained large quantities of the antitoxin, and before going further they devised a method of measuring accurately the exact amount present. It had been found by Behring and Kitasato that, if the poison and the serum antipoison were mixed together in a test-tube in proper proportions, they neutralized each other, and that the mixture when subsequently injected into an animal was inert. They took as a standard of the poison a material of which .3 gramme per 1000 grammes of the body-weight was a certainly fatal dose. For animals of two hundred to three hundred grammes' weight they used ten times this amount,—namely, eight cubic centimetres,—and then added to this two, three, four grammes, etc., of the serum to be tested. The mixtures were then immediately injected into a series of guinea-pigs, and if the poison had not been completely neutralized, this was evidenced in twenty-four or forty-eight hours by local infiltration at the seat of injection and by loss of body-weight. In this way the exact amount of any given serum required to neutralize .8 gramme of poison was ascertained. As the unit of immunity they take serum, of which 1.5 milligrammes neutralizes .8 gramme of poison, and in the treatment of children they employed a quantity of serum containing an amount of antitoxin representing one hundred and thirty to two hundred immunity units.

The investigations were carried out on two hundred and twenty children suffering from diphtheria (proved by bacteriological examination) at all stages and in various hospitals in Berlin. The rough result is that of these two hundred and twenty cases, of which sixty-seven had already required tracheotomy before the treatment was commenced, fifty-two died and one hundred and sixty-eight recovered. Of the one hundred and fifty-three cases in which tracheotomy was not performed, only twenty-two, or 14.3 per cent., died, the cause of death in these instances being in eight sepsis, in

seven pneumonia, in six complications, such as paralysis and nephritis, and in one acute tuberculosis. Of the sixty-seven cases in which tracheotomy was done, thirty, or 44.9 per cent., died, the cause of death being in four sepsis, in twenty-three pneumonia, in two sequelæ, and in one acute tuberculosis. Many of these cases were, however, admitted several days after the disease had commenced and when there was hardly any hope of saving them. The results are very striking, if they are considered in relation to the duration of the disease. Six cases were admitted during the first twenty-four hours, and all recovered; sixty-six were admitted the second day, and only two died. Thus, of seventy-two cases admitted during the first forty-eight hours, only two died. Of these seventy-two cases, tracheotomy was necessary in nine, and the two which died were two of those in which tracheotomy was performed. On the third day twenty-nine cases were admitted, and of these four died; on the fourth day thirty-nine, of which nine died; on the fifth day twenty-three, of which ten died. The percentages of recovery, according to the day of admission after the disease commenced, were, therefore, one hundred, ninety-seven, eighty-six, seventy-seven, fifty-six and one-half per cent., etc.

In most of these cases only a single injection was made, but subsequently, in bad cases, several injections were employed, and the authors think that they might have saved some of those who died, especially from sequelæ (paralysis, etc.), if they had used repeated injections.

Before using the material, it was first ascertained that it was quite innocuous and produced no effect when injected into a healthy individual. When injected in cases of diphtheria, it was only when large amounts were employed that any immediate effect on the pulse or temperature was observed, but in a certain number of cases there was an almost critical fall of temperature and pulse on the day after the injection. The authors explain the fact that, as a rule, the temperature does not immediately fall, because it is only in the very early stage that the disease is pure, and it very soon becomes complicated with septic bacteria, which keeps up the temperature, although the diphtheritic poison has been neutralized. The authors' conclusions are as follows:

1. The fate of the patients depends on the treatment during the first three days of the disease; hence the serum should be injected as soon as possible after its commencement.

2. In mild cases the amount introduced should be at least two hundred immunity

units; in severe cases and in those where tracheotomy is necessary, four hundred units.

3. The injections should be repeated on the same or the following day, according to the general and local symptoms, the total amount varying, according to the severity of the case, from five hundred to fifteen hundred immunity units. In thirty cases where repeated injections were employed, some of them very severe cases, sixteen of them requiring tracheotomy, only four died, these four having had tracheotomy done, with little or no relief to the breathing.

Full details of the methods and cases will be published as soon as possible, and it is to be hoped that this method will be put to the test elsewhere as soon as possible. Already it is being tried in Paris with most satisfactory results.—*British Medical Journal*, June 23, 1894.

#### CHLORAL HYDRATE.

BRODNAX contributes a paper on chloral to the *Polyclinic* of June 30, 1894, of which a part follows:

As an hypnotic, 5 grains of chloral combined with laudanum or with  $\frac{1}{8}$  or  $\frac{1}{4}$  grain of morphine acts splendidly, this combination intensifying the effect of each and depriving the opiate of its stimulating property. With children, by itself, in sweetened water, it has no equal; mixed with paregoric, it is also good.

It is prepared as follows: Cover the amount in a case-vial with glycerin; this dissolves it, and a drop is about a grain. In this form it mixes readily with oil or water, and is more quickly prepared, and more easily divided into doses, large or small. With castor oil the dose 1 to 5 grains renders it less nauseating, and does not gripe, at the same time producing quiet and rest.

Applied to the skin in eruptive diseases (measles, urticaria) as follows: chloral, 10 grains (drops); carbolic acid, 10 grains (drops); water or oil, 1 to 2 ounces, almost instant relief is experienced of the intense itchings; or chloral, 10 drops; glycerin and water, each  $\frac{1}{2}$  ounce, produce the same effect.

As a mouth-wash: Chloral, 10 grains, glycerin and water, each  $\frac{1}{2}$  ounce; a teaspoonful produces a pleasant cool sensation in salivation, as a gargle. After holding it for a moment in the mouth, it should be rejected and an equal amount of the fresh solution may be swallowed. Carbolic acid (10 drops) added makes it more effective in ulceration of the mucous coverings. It seems to act on the nerves locally,

the same as chloroform by inhalation does on the body.

In toothache: Chloral, camphor, glycerin, carbolic acid, equal quantities, applied on a small piece of cotton, after cleaning the cavity, will relieve the pain. (Cover with more cotton to fill the cavity.) If the patient has lost sleep, the author gives a full dose of chloral by the mouth.

For ulcerated sore throat, or ulceration from any cause, such as scalds: Chloral, 10 to 15 drops (grains); water, 1 to 2 ounces, as to age; sugar, to make it palatable to children; a teaspoonful, repeated at short intervals until sleep is induced, then in waking to keep them fully under its influence.

Earache: Camphor, 10 grains; chloral, 10 grains; carbolic acid, 10 grains; castor oil,  $\frac{1}{2}$  ounce. Drop into the ear warm. Fill the ear full, apply a piece of cotton wet in warm water to fill the external ear, then a cloth wrung out in hot water as warm as can be borne.

As an aid to chloroform in surgery or obstetrics, 10 to 15 grains, given twenty minutes before administration of the anæsthetic, seems to intensify the effect, and less than one-half of it is needed to produce the desired effect. In the writer's obstetric practice for the last fifteen years he has used it, and has observed but one case where any unpleasant effects were induced. This was in a woman with her tenth child. He gave the chloral to relax the system (10 grains); in half an hour 5 grains more; in half an hour the chloroform. It affected her almost immediately, and the child advanced and came away in good style, but the woman seemed to be dead drunk and incapable of moving herself. She slept soundly for several hours and awoke all right. She was conscious and would answer questions, but could not move herself. This was the first time she had taken either of the drugs, and she may have been susceptible. Chloral, given before the anæsthetic, seems to tide them over the excited stage of anæsthesia. The first few whiffs of the anæsthetic produce quiet without any excitement. He has used it in a few surgical cases with the same effect. In children, a full dose of chloral, and when sleep comes on they are anæsthetized in that state, and the force often otherwise necessary is avoided.

In coryza, where the Schneiderian membrane is very irritable, chloral, 10 grains (or drops); castor oil,  $\frac{1}{2}$  ounce, used with a soft mop, applied over the surface, after being dried, acts to check the excretion of mucus and lulls the irritation and the head-pains.

The supposed influence of the drug on the heart has not been noticed. In any case where there is a chance of any cardiac trouble, it is an easy matter to fortify the heart with  $\frac{1}{10}$  grain of nitro-glycerin. In none of the author's cases has the chloral "habit" been contracted.

#### A METHOD FOR THE ESTIMATION OF ANTIPYRIN.

Having had occasion to determine the amount of antipyrin in admixture with caffeine, which had been "shaken out" with chloroform from a proprietary headache liquid, it was found desirable to estimate the antipyrin without separating from the caffeine. Accordingly, the following reaction was made the basis of a calorimetric method:

When sodium nitrite is added to an acidified, dilute solution of antipyrin, a blue-green color is produced, which is still perceptible in dilutions of 1 in 20,000. In more concentrated solutions a crystalline precipitate of the same color is formed.

These results are due to the reaction between the liberated nitrous acid and the antipyrin, by which a compound is formed that has been shown to be nitroso-antipyrin.

It was determined that a standard solution, that will not turn yellow or fade in from twelve to twenty-four hours, can be made by dissolving .02 gramme of antipyrin in twenty-five cubic centimetres of water, adding 1.6 cubic centimetres of one-per-cent. sulphuric acid, and a cubic centimetre of one-per-cent. solution of sodium nitrite, and then diluting to one hundred cubic centimetres.

When preparing a solution of an unknown amount, for comparison with the standard, a few preliminary trials must be made to determine the amount of reagents required to fully develop the color and not be in such excess as to produce a yellowish tinge in the time required.

To avoid precipitation, the solution must not be more concentrated than 1 in 500.

When thus properly prepared, the solution can be diluted until the color corresponds exactly with that of the standard.

A little calculation will then show the amount of antipyrin present.

Tubes or beakers of white glass placed upon a white surface are convenient for the color comparisons.

Since the reagents employed do not react with other substances, except pyrazolone compounds, which are not of frequent occurrence, and as antipyrin is readily extracted from mix-

tures by the use of chloroform, this method admits of wide application.

It may also be mentioned that as this reaction does not take place in the presence of nitrites, but requires free nitrous acid, the incompatibility of antipyrin and (acid) sweet spirit of nitre may be prevented by having the spirit neutral or neutralizing with potassium bicarbonate.—SCHAAK, *American Journal of Pharmacy*, July, 1894.

#### ON THE TREATMENT OF CERTAIN FORMS OF ADVANCED CANCER OF THE UTERUS.

In the compass of this paper the author confines his remarks to the treatment of those forms of cancer of the uterus that, on account of the extent of the disease, are totally unsuitable for any form of operative interference,—that is, vaginal hysterectomy or supravaginal amputation of the cervix.

He comes to the conclusion that for practical purposes we may divide these diseases into three divisions.

1. Those in which the disease is limited to the uterus, this organ being movable and readily drawn down to the vulva.

2. Those cases in which the disease had extended beyond the neck of the uterus into the surrounding cellular tissue, thus more or less fixing the uterus in this situation, and perhaps the roof of the vagina being slightly involved.

3. Those cases in which the disease extended beyond the above limits, invading the vagina and possibly the bladder or rectum, or indeed both these organs.

It is to the treatment of the two latter forms of the disease to which he alludes, and he disposes first of those cases included in the third division first.

When the disease has extended to the vaginal walls, implicating the bladder and rectum, nothing but purely palliative measures can be adopted. Our aim must be to make these poor women as comfortable as possible by relieving their pain and keeping the parts as clean and sweet as we can. To accomplish the first object there is nothing which answers so well as morphine and belladonna suppositories introduced several times a day, if necessary. He has found relief given in many of these cases by, in the first place, syringing the vagina thoroughly well out with a solution of iodine and water, and here it should be stated that this be done through a speculum. The writer has specula of different lengths, so that if the vagina is much involved he can introduce a short one, such as will permit as good a view as possible.

Having syringed the parts as thoroughly as possible, he proceeds with dry tampons of cotton wool to wipe the parts well, removing as much as possible of the sloughy *débris*, which is sure to be present, and finally he applies a solution of chromic acid (2 drachms to 1 ounce) to all the diseased surfaces, being careful not to allow this solution to run on to the healthy tissues. These are protected by applying a saturated solution of bicarbonate of sodium. Finally, a long strip of gauze is introduced and a morphine suppository placed in the rectum.

The vagina is kept syringed out with some antiseptic solution some three times a day. In a few days a quantity of sloughy material will come away and the discharge be very much less offensive, and the pain will be relieved in every case in a most marked degree. The patient improves in general health and the appetite returns. For after-treatment he adopts the plan of inserting a small ball filled with iodoform or iodol, and a strip of iodoform gauze attached to it; this has the effect of keeping the parts wonderfully clean. With respect to medical treatment, our great aim must be directed to giving tonics, keeping the bowels regularly opened, and improving the general tone of the patient as much as possible. Tabloids of Chian turpentine and ichthyol are useful.

In those cases included under the second division, however, there is a much brighter outlook, and it is in these cases that we can hope not only to give relief, but to remove the diseased parts almost as surely and as effectually as we do in those cases which are suitable for complete or partial extirpation.

It must be borne in mind that the post-mortem examination of a number of cases showed that the disease was limited to the cervix and os. In other cases the body was implicated, but very rarely to such an extent as the cervix, thus pointing to the supposition that the disease usually commenced in the cervical canal and then extended outward to the cellular tissue beyond. It must be further borne in mind that only in some of the very advanced cases did the patient suffer from secondary growths, although it is true that there were quite a number who had their lumbar and sacral glands infiltrated with the disease, but in many of these cases the glands did not appear as if they had long been affected. We may, therefore, in this class of disease look upon it as purely a local affection, and we may hope if we can remove the growth that our patients may recover, and possibly be radically cured.

The plan that commended itself most to the writer was that practised by Dr. Marion Sims; the thorough clearing out of the advanced disease, however, appeared to him of paramount importance. The curettes which were adopted by this surgeon and by others did not commend themselves; in fact, disaster followed their use. The author has seen on more than one occasion the curette passed completely through the uterine wall into the peritoneal cavity; moreover, after the uterus has been apparently thoroughly curetted, on examining the surface it has been rough and uneven, with ridges here and there; in fact, these curettes were ill adapted to the purpose. Bell's dredgers also proved inefficient, as they were too pliable and their calibre was too small. The writer then decided to have an instrument constructed somewhat after the principle of Bell's dredger, by which the cutting blades could be increased in size by means of a screw in the handle, and furnished with watch-spring knives so shaped as to enable him to scrape out the contents of the uterus by simple rotation. It is worked by means of a screw. By means of this screw the blades, which when first introduced lie flat on the central rod, are made gradually to expand until they represent an area of about one and a half inches in diameter. Here was furnished an instrument by means of which the writer was enabled to remove the whole contents of the uterus with comparative ease, and as the blades are not too sharp, no mischief can be done with them, and very little bleeding follows its use. By using this instrument a perfectly smooth, even surface is left, and this is of the greatest importance, as, if the surface is uneven, the application of the caustic is rendered uncertain and unequal, as in those parts which are elevated it would naturally penetrate very much less deeply than in the depression.

The writer advocates as a caustic absorbent wool soaked in a solution of chloride of zinc. There is, however, a great difficulty in getting this wool prepared strong enough, as if a saturated solution is used the wool becomes unevenly saturated, and it is knobby and hard. After saturation the wool is carefully dried and kept in a firmly-stoppered bottle ready for use. In very bad cases a paste of chloride of zinc is used, prepared at the time of operation, and the wool soaked in the paste, getting it as dry as possible by squeezing it out in a piece of gauze and then packing the cavity which has been cleared out with it. Great care has to be exercised in packing to prevent the caustic from running over the healthy vaginal walls.

In applying the dredger, the patient, being thoroughly anesthetized, is placed in the lithotomy position with Clover's crutch. The vagina is then thoroughly irrigated with carbolyzed water, a Sim's speculum being introduced. By means of stick sponges the vagina is then dried. The dredger closed is now passed into the diseased canal and rotated from left to right. At the same time the blades are opened by means of the screw in the handle. The dredger very shortly becomes full of broken-down diseased tissue. This is readily removed by rinsing the blades in a basin of warm carbolyzed water. It is then reintroduced and the blades slowly opened, the instrument being removed from time to time and rinsed until it is found that the parts from whence the disease has been removed presents a perfectly smooth surface. There is usually but little bleeding, nothing more in fact than a general oozing. This is readily arrested by having some water as hot as possible and by means of stick sponges applying this to the cavity; when this is found to be fairly dry, the process of packing commences. Should there be much bleeding, it will be advisable to check this either by touching with Paquelin's cautery, or plugging with gauze firmly, or applying perchloride of iron lint. In this case the packing with the zinc-wool must be postponed until the next day, when it can readily be done in the ward.

Packing is best done by having very small pieces of the wool and packing these in with uterine forceps, an assistant steadying the uterus by pressure above the pubes. It is astonishing what a quantity of wool can be packed in these cavities. When the cavity is quite firmly filled, a ring pessary with rubber diaphragm is placed over the mouth. The object of this is to prevent the action of the chloride of zinc at the orifice from being neutralized. The vagina is now plugged with tampons of wool soaked in a saturated solution of carbonate of sodium. The writer finds it a good plan to introduce one tampon thoroughly soaked and allow it to remain in for a few minutes, and then remove it so as to neutralize any of the caustic which may have leaked onto the vaginal wall. Three or four plugs, soaked, are now passed into the vagina, and here again it will be found a great convenience if they are tied together in the form of a kite's tail, as it saves so much trouble when removing them. The patient is now returned to bed.

The next day the carbonate of sodium tampons may be removed and fresh ones introduced, or they may remain in for some few days. Should there be no tenderness or rise in

temperature the chloride of zinc packing need not be removed for four or five days; this is most easily extracted by means of Marion Sim's screw, which consists of a long straight steel rod with a very fine double screw, like a very small corkscrew, at the top. After the packing is removed the vagina and cavity should be well syringed out with some antiseptic solution. Weak iodine and water is efficient. A piece of iodoform should be packed into the cavity. This should be removed night and morning and the part syringed on each occasion. In syringing the vagina the writer employs a full-sized Ferguson speculum, as it is much easier to syringe out any sloughs or *débris* that may be detached.

At the end of from seven to ten days the slough created by the caustic will become detached, and can readily be removed by means of uterine forceps. The slough should always be allowed to become quite loose before being removed or troublesome hemorrhage may follow. A healthy, clean, granulating surface usually is left. In some cases it may be necessary to repack the cavity if the disease does not appear to be removed. Should portions of the surface appear roughened, with nodules present here and there, they should be removed by injecting a few drops of solution of chromic acid (1 drachm to 1 ounce) directly into the growth by means of a long hypodermic syringe. This has a very marked effect, causing the nodule to become hard, and this after another week or ten days detaches and can readily be removed.

With regard to medical treatment, he administers small doses of bromide of arsenic with good effect. Chian turpentine also appears in some cases to tend to cleanse the parts. He has had some tabloids prepared composed, some of Chian turpentine, chloride of gold and sulphur, others of turpentine, pyoktanin, and ichthyol. These tabloids have proved most successful in these cases.

Marked beneficial effects have followed the above methods of treatment in his hands. Some have been treated some months ago and are still free from any recurrence. The day after using the caustics the patients expressed themselves as suffering no pain whatever and also said their old pain had disappeared.—FRED. BOWREMAN JESSET, *Medical Press and Circular*, June 20, 1894.

#### TREATMENT OF ACNE.

The internal treatment must vary with the indications. For the external treatment the "don'ts" are as important as the indications for

positive treatment. In nearly all acnes hot water should be freely used. Perfumed and patent soaps should be condemned. White Castile soap and Pear's unscented soap are the most desirable. The tincture of green soap is excellent when there are comedones present, but is irritant if used too liberally. In pustular acnes, when there are no contraindications, sulphide of calcium, in pill form, best sugar- or gelatin-coated, is useful. Ichthyol, in 5- to 10-drop doses, answers the same purpose,—viz., tends to stop pustulation.

Where the eruption shows evidence of acute inflammation, sedative astringent applications must be made. Where the condition is of long standing, stimulant applications are indicated, with the object of opening the ducts and forcing the glandular action. In indurated acnes, with deep-seated pus lesions, surgical interference is necessary. The lesions should be opened and treated as small abscesses. Care must be exercised with the sulphur preparations to avoid chemical combinations with a possible metallic salt previously used.—DYER, *New Orleans Medical and Surgical Journal*, June, 1894.

#### REPORT ON THREE YEARS' USE OF NAPHTHOL.

The first noticeable effects of  $\beta$ -naphthol in typhoid fever are a more or less free and continuous diaphoresis, occurring very soon, and a gradual loss of the peculiar apathetic countenance; sleep becomes more natural and prolonged; and on the third or fourth day the character of the pulse changes, becoming slower and softer; this change seems invariably to happen before the fall in temperature takes place,—that is, on the day when the temperature ceases to rise. The offensive odor of the stools gets less each day, and the temperature begins to fall about the fourth or fifth day of the treatment, and becomes normal in three or four days after, without resulting in much loss of strength and without danger, for the writer has never noticed any toxic symptoms from  $\beta$ -naphthol.

There has happened on two occasions a return of the fever after the lapse of three weeks from the time when the temperature became normal, and the same treatment after three days' watching has had to be repeated. This he regards as possible evidence of the value of the treatment, assuming the second attack to be due to renewal of activity in the morbid agents, whose development had been suspended

by the antiseptic, these agents not having been removed from the bowel, in consequence of the obstinate constipation succeeding the first attack in both cases. He now prevents constipation and maintains the treatment for a week after temperature becomes normal.

There of course is nothing new in the use of naphthols or naphthalin in typhoid, but it is probable that the comparatively poor results hitherto recorded may be due to the defective method of administration, which has almost always been in the form of powder. Now, solid naphthol is irritant, and the powder particles are apt to increase the intumescence of the affected intestinal glands when they lodge on them, and so tend to undo what good may result from the antisepsis. The reason of this lies in the insolubility of  $\beta$ -naphthol in water; this may readily be overcome by first directing the  $\beta$ -naphthol to be dissolved by heat in olive or sweet almond oil (ten times its measure), and then the resulting solution to be emulsified with powdered gum acacia, preferably; this, sweetened and flavored, makes a palatable emulsion. Being somewhat pungent, it requires watering for children; all take it well. The author employs 4-grain doses every four hours for adults, in a mixture such as this:

R  $\beta$ -naphthol,  $\mathfrak{z}\text{i}$ ;  
Ol. olivæ opt.,  $\mathfrak{z}\text{x}$  (dissolve with heat);  
Pulv. gum acaciæ, q. s.;  
Ol. cassiæ,  $\mathfrak{m}\text{vi}$ ;  
Glycerini,  $\mathfrak{z}\text{i}$ ;  
Aque, ad  $\mathfrak{z}\text{viii}$ .

M. ft. emulsio, capiat  $\mathfrak{z}\text{ss}$  every four hours.

It seems that though a large portion of the  $\beta$ -naphthol passes down the alimentary canal unabsorbed and unchanged, rendering the entire tract less septic, some portion is absorbed, and acts as a diaphoretic and soporific.—E. H. EMBLEY, M.B., *Australasian Medical Journal*, May 20, 1894.

#### SOME OF THE USES AND ABUSES OF THE NITRITES.

The nitrites are a group of remedies which includes the nitrites of sodium, potassium, and nitro-glycerin, or glonoin, as it is now named in the new Pharmacopœia.

They are a somewhat important class of remedies, being prompt in action, but of short duration, and demanding their frequent administration to maintain continued effects.

In order to have an intelligent understanding of their therapeutic uses, it is necessary to know something of their physiological action; and while clinical experience may be the

touch-stone which solves the mystery of remedial agents, a good knowledge of pharmacodynamics will often restrain or prevent the employment of remedies whose administration would prove prejudicial to recovery. When taken they cause a sense of cerebral fulness, flushed face, pain in the head, rapid heart-beat, and lowered blood-pressure. The rapidity of heart-beat is caused by their depressant action on the inhibitory branches of the vagus, and to the sudden relaxation of the terminal arterioles in front from vaso-motor paralysis. The flushed face is caused by the dilatation of the capillaries, and the lowered blood-pressure to the lessened resistance in front. It may be accepted as a fact, to which there are but few exceptions, that when there is very little resistance in front,—that is, lowered blood-pressure,—the heart endeavors to make up or compensate the loss by increasing the number of its contractions, and when we employ an agent like the nitrites, which also paralyzes the inhibitory centre, the number of heart-beats is greatly increased.

On the nervous system their action is not so marked, but they take rank as sedatives or depressants, confined to the motor tract of the cord. In the blood they transform hæmoglobin to methæmoglobin, and thus lessen or destroy the oxygen-carrying function of the corpuscles. The blood becomes venous and of a chocolate color, with consequent lowering of the body temperature, due to decrease of oxidation and increased radiation of heat from the dilated capillaries.

The diseases in which the nitrites have been found beneficial are those of a spasmodic nature, whether local or general, such as whooping-cough, spasmodic cough, hystero-epilepsy, and convulsions of children. Hystero-epilepsy and simple hysteria he has found yield to a single dose of glonoin. In interstitial nephritis the nitrites, especially the glonoin in combination with digitalis, are useful. In this disease we have heightened blood-pressure, owing to spasm or constriction of the terminal arterioles, and an hypertrophied left ventricle, a condition of affairs which, if not cured, is relieved by the nitrites. Death from croupous pneumonia always comes from cardiac failure. When there is impending failure of the right heart from over-distention, the nitrites, by dilating the arterioles, thereby diminishing the work which the heart has to do and causing an equilibrium in the distribution of the blood, have been found of benefit, particularly if employed on the first appearance of the engorgement.

Migraine, when there is a spastic or constricted condition of the cerebral vessels, is sometimes relieved by their administration. Other conditions of acute cerebral anæmia are also rapidly relieved by them, such as syncope and anæmic epilepsy.

Many other similar conditions which will suggest themselves are greatly benefited by the use of the nitrites. Cardiac dyspnoea, attended by high arterial tension, will be greatly relieved by their employment. The pain due to aneurismal pressure is sometimes alleviated by them. Generally, if they will do good in a certain case, their action is prompt.

The contraindications are important.

We find the surface pale and cold in shock, the heart beating feebly and often the beat greatly increased in frequency, complete muscular relaxation, and depression of all the vital functions. The pale, cold surface is caused by the paralysis of the vaso-motor system and by the recession of the blood to the muscles and abdominal viscera. Now, why, in such a condition, should such paralyzing and depressing agents as the nitrites be given, except we believe in the law of similars? Is it prudent or good therapeutics in such a case to give a remedy whose chief action is to still further depress that weak heart, to still more paralyze the vaso-motor system with which the integrity of the circulation and blood-pressure is in such intimate connection and relation? The author firmly believes this procedure to be wrong.

During the past year two eminent men have died in this country, and the public press informed us that when they were in extremis, "nitro-glycerin, a powerful heart stimulant," was given to brace up the flagging heart and prolong their lives. Let us investigate this statement and see if we can elicit the distinguishing characteristics of heart stimulants. We find they cause (*a*) increase in the number of heart-beats, (*b*) rise in the blood-pressure, (*c*) increase of blood in the cerebral arteries. Do we find such to be the specific action of the nitrites on the circulatory system? No, except that the heart-beats are greatly increased in frequency, caused by paralysis of the inhibitory nerve, and the dilatation of the peripheral vessels from relaxation of their muscular coats through vaso-motor paralysis. Consequently there is a loss of resistance in front which immediately results in a great fall in blood-pressure, and the resultant action serves only to intensify the already existing state of cardiac insufficiency and adynamia.

If the physiological action of a remedy is to serve as a guide for its intelligent administra-

tion in disease, it is difficult to understand why the nitrites are given in cases of genuine intrinsic cardiac failure.

"A perfect circulation" is one which empties the veins and fills the arteries,—the very antithesis of the condition produced by the use of the nitrites. Its employment, therefore, in essential cardiac adynæmia is one fraught with great danger. In threatened heart-failure from alcoholism, and when it has actually taken place from chloroform or ether, he believes the administration of the nitrites to be prejudicial to recovery, as their dominant action is to weaken the pulse and lower the arterial tension.—JAMES NEWELL, M.D., *Canada Lancet*, July, 1894.

#### THE THERAPEUTICS AT THE INTERNATIONAL MEDICAL CONGRESS.

It may happen that the most successful and largest medical congresses are not particularly rich in therapeutic work. Yet, after all, when the heat and smoke of the day are cleared away, one feels that the important query is, Has anything been said or read which will make the treatment of diseases more sure and effective?

We have been looking over the records of the International Congress at Rome, and have tried to find what practical therapeutical suggestions were made at that time.

The results of our study, which has been facilitated by a critical review in the *Gazette des Hôpitaux*, have not been very fruitful, nor yet altogether barren. For example, DR. PETRESCO, of Bucharest, comes forward again with further facts regarding his treatment of pneumonia with large doses of digitalis. He has employed his method now for thirteen years and treated eleven hundred and ninety-two cases, and he has reduced the mortality to 1.22 and 2.66 per cent., while under other treatment the mortality ranges from 7.15 to 35.50 per cent.

A year ago we discussed Petresco's method, which consists of giving 8 or even 12 grammes of digital leaves in twenty-four hours. According to the author, it invariably jugulates acute lobar pneumonia in a few days.

DR. GOFFREDI, of Naples, calls attention to the value of lactose as a diuretic, particularly in heart-disease. It is not so effective in nephritis. Diarrhoea is sometimes caused by the lactose.

DR. PUCCI praises very highly the use of phenocoll in malaria. He gives from  $\frac{1}{2}$  to 1 gramme a day.

After having broken up the paroxysms, the drug is continued five or six days in association with quinine or arsenic. It is also very useful in malarial neuralgia.

A curious contribution to therapeutics is that of DR. SANCHEZ HERRERO, of Madrid, who recommends a solution of bromide of potassium, 50; iodide of potassium, 5; and water, 500, in the treatment of epilepsy. Dr. Herrero is evidently not familiar with some of the very ancient formulas for epilepsy, including that of Brown-Séquard. We should add that the doctor adds to his treatment hypnotic suggestion twice a week, and that he has cured nineteen cases out of thirty.

DR. A. MURRE, of Bologna, makes a protest against the abuse of cold water in the treatment of chlorosis, but at the same time thinks that cold water, properly used, is better than drugs in this condition.

DR. TISON thinks that the nitrate of aconitine is useful in facial erysipelas, shortening the attacks and lessening the pain. He gives  $\frac{1}{100}$  grain ten times a day.

VON ZIEMSEN, of Munich, would have us return to the use of transfusion of blood, particularly in grave anæmias.

The best method is the arm-to-arm one without defibrinating, but if this is not practicable, he recommends subcutaneous injection of non-defibrinated blood. This ought to be given under chloroform and followed by massage, as the process is very painful. It is safe to say that a treatment involving regular anæsthetization of the patient will hardly become popular, and certainly is not safe.—*Medical Record*, July 14, 1894.

#### THE MEDICAL TREATMENT OF ICTERUS DUE TO RETENTION.

In an article upon the above subject, DUJARDIN-BEAUMETZ (*Bull. Génér. de Thérapeutique*, June 15, 1894) believes that, previous to surgical interference in the treatment of icterus, diet is of the utmost importance, and this should consist preferably of raw white meats, green vegetables, and fruit. The moderate use of eggs is also of advantage. All alcoholic beverages should be avoided. For drinking purposes, alkaline waters, such as Vichy and Carlsbad, to which a little milk should be added, are to be preferred. Tea and coffee may be allowed, especially tea, which, in the cases under consideration, acts as a general stimulant, enhances digestion, increases the bodily energy, and excites the heart, all this tending to improve an impaired nutrition.

Vichy pastilles are recommended, each one of which contains five-twelfths of a grain of bicarbonate of sodium; forty pastilles represent, therefore, sixteen grains of the sodium salt. Being slowly dissolved, these pastilles act as a sialagogue, through which action a large quantity of saliva will accumulate in the stomach, the remedy producing in this way good therapeutic effects. In regard to other medicinal agents, the author advises the use of certain antiseptics, such as salicylate of sodium and asaprol, these to be preferred to other similar remedies. At each meal the patient should take an 8-grain cachet of salol and another 8-grain cachet of asaprol, or a tablespoonful of the following solution, accompanied with the salol cachet:

R Salicylate of sodium, 240 grains;  
Water, 8 ounces.

#### PUERPERAL ECLAMPSIA TREATED BY VENESECTION.

The following interesting case from a practical stand-point is reported by McLEOD in the *Australian Medical Gazette* for May 15, 1894.

Mrs. C., aged eighteen. When labor began she was eight months pregnant with her first child. Her friends thought she was having hysterical fits, and sent for the writer. She had three of these "fits" before his arrival. He found the patient in bed and only partially conscious. Pains were regular, and her pulse was over 100. She presently had a "fit" which settled the question of diagnosis.

On examination the os was found dilated to the size of a two-shilling piece; the head was presenting and the membranes unruptured. The bladder was emptied and 40 grains of bromide of potassium injected into the rectum.

During the next half-hour three convulsions occurred; thereupon the os was sufficiently dilated to apply the forceps, and a living male child was delivered in about fifteen minutes. The placenta came away entire. The uterus contracted firmly, and no post-partum hemorrhage whatever occurred. The convulsions continuing after the uterus was emptied, more bromide and chloral was injected into the rectum.

Returning three hours later, the author found six convulsions had occurred. The pulse was now 120 and the temperature 103°. Within the next three hours, and after a further dose of bromide and chloral per rectum, eight convulsions occurred. The patient was now quite comatose and the breathing was stertorous.

As a last resort he proposed bleeding, and

with difficulty got the consent of the parents. He allowed about sixteen ounces of blood to run from the vein in the right arm. No more convulsions occurred, the breathing became quieter, and when he visited her again—thirteen hours after delivery—the pulse had fallen to 85 and the temperature to 101°. Consciousness was returning, and she could recognize her friends. Her condition gradually improved, and when seen on the eighth day she was quite clear mentally, but inclined to be quiet. She made a perfect recovery.

Probably, had there been a profuse post-partum hemorrhage immediately after the emptying of the uterus, the convulsions might have ceased at that stage.

#### SOME PRESCRIPTIONS.

In a recent lecture on the art of prescribing medicines, DUJARDIN-BEAUMETZ (*Bull. Génér. de Thérapeutique*, May 30, 1894) treats of external medication, and publishes several combinations devised by himself and other practitioners, as follows:

*For an Eye-Wash.*—All former eye-washes made up of nitrate of silver, atropine, eserine, or sulphate of zinc have of late been substituted by antiseptics, chief among which is corrosive sublimate, according to this formula:

R Bichloride of mercury,  $\frac{1}{2}$  grain;  
Distilled rose-water, 5 ounces;  
Sydenham's laudanum,  $\frac{1}{2}$  drachm.

For an eye-salve:

R Red oxide of mercury, 15 grains;  
Crystallized acetate of lead, 15 grains;  
Powdered camphor,  $7\frac{1}{2}$  grains;  
Vaseline, 288 grains.

*Sternutatory Powders.*—GRELLETY has proposed the following in acute coryza:

1. R Betol, 40 grains;  
Menthol, 4 grains;  
Cocaine, 8 grains;  
Powdered coffee, 72 grains.

DIEULAFOY, according to Huchard, recommends this combination:

2. R Salicylate of bismuth, 240 grains;  
Camphor, 80 grains;  
Cocaine hydrochlorate,  $\frac{3}{4}$  grain.

JULIAN advises the use of this ointment:

3. R Menthol,  $3\frac{1}{2}$  grains;  
Boric acid, 80 grains;  
Vaseline, 800 grains.

**Tooth-Powders.**—The following formula is recommended by GALIPPE, and has, according to Dujardin-Beaumetz, given excellent results:

1. R Boric acid, 400 grains;  
Phenic acid, 16 grains;  
Thymol, 4 grains;  
Water, 1.7 pint.

To this may be added, with advantage:

Essence of peppermint, 20 drops;  
Tincture of aniseed, 2½ fluidrachms;  
Cochineal, sufficient quantity to color it.

MAGITOT has proposed this simple combination:

2. R Thymol, 8 grains;  
Borax, 16 grains;  
Distilled water, 15 ounces and 5 drachms.

An antiseptic tooth-powder, as recommended by LE GENDRE, is composed as follows:

3. R Finely-powdered boric acid, 40 grains;  
Chlorate of potassium, 32 grains;  
Powder of guaiac, 24 grains;  
Prepared chalk, 64 grains;  
Powdered carbonate of magnesium, 64 grains;  
Essence of rose or mint, 1 drop.

#### COCAINE IN MINOR SURGERY.

The following case may be of interest to those members of the profession situated in isolated country districts where a second medical man is not available for assisting at operations. It is also with the hope of inducing others with larger opportunities to give cocaine a further trial that this report is given.

P. W., a half-caste, who had for some weeks previously been operated upon for hydatids of the liver, presented himself with symptoms of a right-sided empyema. An exploratory puncture revealed the presence of fetid pus with traces of bile, and by means of a Dieulafoy's aspirator about four pints of extremely fetid purulent fluid were withdrawn. This afforded some temporary relief; but a few days after his condition was worse than ever, and an incision with proper drainage was urgently called for as offering the only chance of saving life. His very feeble pulse, as well as the universal prejudice at present against chloroform, forbade the use of this agent, and ether, apart from the fact that a person suitable as administrator was not available, was contraindicated by the existence of a chronic bronchitis. Under these circumstances the writer determined to use cocaine, and proceeded as follows:

He first applied some ether spray to the part

which was to receive the first puncture of the needle, and, having filled a hypodermic syringe with a one-per-cent. solution of cocaine, injected the skin lying in the future track of the knife with it, pushing the piston of the syringe slowly home as the point of the needle traversed the tissues. This injection was made in the meshes of the true skin, and the anæsthetized area measured about two and a half or three inches in length. On withdrawing the needle and waiting for four or five minutes, he was enabled to make a painless incision through the whole thickness of the skin; but on attempting to deepen the wound the patient became sensitive of the knife, which, therefore, was laid aside for the moment and a second injection of cocaine injected into the connective and muscular tissue at the bottom of the cut, having first stopped all oozing of blood (an important point) by the application of a warm sponge. In a few moments he was again enabled to proceed with the dissection in a painless manner, and after a third injection of a few more drops, the operation as at first planned was completed. But on account of a somewhat close approximation of the lower ribs, the opening obtained was not wide enough to carry a drainage-tube of proper size, and the operator decided to remove a piece of the lower rib. This was again done painlessly, after injecting some cocaine under the periosteum. The total quantity used amounted to a little over one grain.—ALTMANN, *Australian Medical Gazette*, May 15, 1894.

#### LEGUMINE AS A SUBSTITUTE FOR A MILK DIET.

BOVET (*Bull. Génér. de Thérapeutique*, May 30, 1894) relates four cases of gastric disorders in which a milk diet was not well borne, and where the administration of legumine gave satisfactory results. This remedy was prescribed in as high doses as 16 drachms a day, in the case of adults. To one patient it was given for three months, to the exclusion of all other articles of food, during which time the individual gained four pounds in bodily weight. According to the author and MARINES, who has made a special study of the subject, legumine is not only a medicament, but a food, owing to the phosphated and albuminoid elements which it contains.

#### HOME-MADE BEEF-POWDER AND HOW TO PREPARE IT.

DR. WILLIAM R. HUGGARD (Davos Platz, Switzerland) writes in the *British Medical Journal* of June 9, 1894: Some of the beef-

powders in the market smell and taste of the chemist's shop, and are not readily taken by an invalid whose palate requires to be coaxed. A happy idea struck the writer several months ago that beef-powder might without difficulty be prepared fresh and on a small scale by any ordinary cook. The experiment was made, and the result was satisfactory beyond expectation. Beef-powder made at home is appetizing, has a delicate aroma and flavor, and can be taken with pleasure by invalids who turn with aversion from ordinary food. If a little pepsin be taken at the same time, it is digested even when the ordinary peptonized foods are not retained. The mode of preparation is simple. Lean beef is cut into small pieces; these are put into boiling fat, dripping, or butter for a couple of minutes until the surface is browned. They are then removed from the fat and placed on a strainer for a few moments. Afterwards they are placed in a mincing-machine. The resulting mince is placed in a slow oven and dried. The drying process may take from five to twenty-four hours, or even longer, according to the heat employed. When thoroughly dried, the meat is quite crisp, and can be ground in a coffee-mill that has not been used for any other purpose. In the drying process the meat loses a trifle more than four-fifths of its weight. This beef-powder can be taken in various ways,—with hot water or soup, with mashed potatoes, with bread and butter in a sandwich, or with a little pepsin in a starch wafer. The writer has given this home-made beef-powder with such excellent effect in several cases where there was much difficulty with food that he thinks others may find it useful.

Beef-powder, carefully prepared according to the directions above given, has an agreeable flavor, and admits of being used like potted meat by persons of delicate or fanciful appetite. By regulating the heat applied in making the powder, the albuminous constituents need not be coagulated, but merely dried, and the digestibility of the powder would then be increased; in any case, the finely-divided condition would facilitate digestion. A very good beef-tea may be made from the powder by infusing it in moderately hot water. For the preservation of the powder it would be necessary to keep it from contact with atmospheric air and to avoid the access of mites or similar deteriorating influences.

#### THE TREATMENT OF MYELITIS.

In the issue of *La Tribune Médicale* for June 7, 1894, the following advice is given. In

acute myelitis, absolute rest in bed, the application of counter-irritation to the spine, and for the first eight days of benzonaphthol. After the eighth day two pills, made up according to the following prescription :

R Ergotin, gr. i;  
Capsicum, gr. ss;  
Powdered licorice, sufficient quantity.

In chronic myelitis, apply for a week or more active counter-irritation to the spine and a deserts- spoonful of the following mixture internally :

R Iodide of strontium,  
Iodide of potassium, of each, ʒiiss;  
Glycerin, ʒi;  
Syrup of orange, ʒiv.

After this has been given for from three weeks to a month, use the following pill :

R Nitrate of silver, gr. ¼;  
Powdered licorice, sufficient quantity.

Every morning cold douches should be applied to the body, composed of alcohol and water, and a constant current of electricity should be applied to the spine.

#### BROMOFORM IN THE TREATMENT OF WHOOPING-COUGH.

CARPENTER, in the *Polyclinic* of June 16, 1894, writes on bromoform. He says that bromoform is a colorless liquid produced by the action of bromine upon alcohol in the presence of an alkali. In practice, milk of lime is saturated with bromine, then alcohol is added and the mixture distilled. It is also prepared now by the action of sodium hypobromite upon acetone by a reaction analogous to that used in the manufacture of chloroform. Bromoform should be prescribed in colored bottles, as it is not a stable preparation, and if exposed to the air it volatilizes. When exposed to heat or light it is gradually decomposed, becoming a brownish-red, due to the free bromine which is liberated. Bromoform is slowly eliminated by the kidneys.

The good effect of the drug in whooping-cough is partly, at least, due to its acting as a local anæsthetic upon the pharyngo-laryngeal mucous membrane. Some writers have gone so far as to claim specific properties for the drug. It certainly does moderate the violence of the individual paroxysms, diminishing their severity and frequency, often stopping the vomiting in twenty-four hours, and in many cases it shortens the duration of the disease.

Bad effects have rarely been seen, and never

from small doses. Small doses in some cases have failed to be of service, while large ones have made the child stupid and sleepy. In a few cases, where the child had received a larger dose than had been prescribed, narcosis was produced, but the patient was readily revived. The symptoms of poisoning have been pallor, staggering, dilatation of the pupil, coma, heart-failure, and collapse.

Bromoform is given in 1- to 5-drop doses three or four times daily, a child of one year receiving 1 to 2 drops three times a day; a child from two to four years, 2 to 4 drops three or four times a day; a child from five to eight should receive 4 to 5 drops four times daily, according to the number and frequency of the attacks. Bromoform is difficult to drop. It is usually given dropped on sugar or in water; care must be taken that the pearly drops floating about in the water are swallowed.

When we cannot trust the attendant to drop the medicine, it may be given in the following manner:

℞ Bromoform, ℥xlviii;  
Alcohol, ℥iv;  
Tr. cardamomi comp., q. s. ad ℥i. M.  
Sig.—gi t. d. in water.

If the administration of the drug be discontinued too soon, relapses may occur.

#### THE ACTION OF CHLOROFORM ON THE CARDIAC RHYTHM.

It was shown by the Hyderabad Chloroform Commission that the rapid temporary fall of blood-pressure which often occurs when chloroform is suddenly administered is due to a reflex slowing or inhibition of the heart through the vagus nerves. J. G. MACWILLIAM (Prov. Royal Soc., vol. liii.) has worked out the way in which chloroform brings about this and other variations in the cardiac rhythm. He finds, in cats and rabbits, the same two stages in the effect of chloroform on the cardiac rhythm as is observed in man,—namely, a stage of acceleration followed by a stage of slowing. These two stages are still manifest after the accelerator nerves are divided. The acceleration, therefore, is not due to impulses reaching the heart by the accelerator nerves. After the vagus nerves are divided, with or without the division of the accelerators as well, the rapid heart-beat consequent on the removal of the restraining action of the vagi can still be slowed down by the action of chloroform, but this is not preceded by any further quickening. The stage of acceleration is, therefore, due to

the chloroform more or less paralyzing the inhibitory action of the vagi. That slowing is produced after the vagi are divided, although it is not so great as when they are intact, shows that the slowing is not entirely due to a stimulation, reflex or direct, of the cardio-inhibitory centre. It is further shown that the slowing is not due to the stimulation of the local inhibitory mechanism of the heart, for the administration of atropine, which paralyzes this mechanism, does not prevent the slowing being produced by chloroform. MacWilliam's researches, therefore, give additional proof of the direct action of chloroform on the heart. He concludes this part of his work with these words: "It appears that chloroform acts on the heart and distinctly slows its rate of beat through a depressing or retarding influence exerted on the intrinsic rhythmic mechanism of the organ." In the remaining part of the paper the relation of the rate of beat to the blood-pressure and the influence of the direct and reflex stimulation of the cardiac nerves is discussed. Reflex acceleration is not due to impulses reaching the heart by the accelerator nerves, for it may be readily obtained after they are divided, provided that the vagus nerves are intact. Muscular exertion causes acceleration of the heart, partly by diminishing the influence of the vagi. Animals with great running and staying powers have a slow pulse, usually markedly restrained by the cardio-inhibitory centre, and so capable of rapid acceleration by inhibition of that centre. This is strikingly seen when the effects of the division of the vagi in the rabbit and the hare are compared. In the rabbit, removal of the vagus influence produces but little change in the rate of beat, while in the hare the pulse may rise from 64 to 264, showing the marked action of the cardio-inhibitory centre, and consequent power of rapid acceleration of the heart in the latter.—*British Medical Journal*, June 2, 1894.

#### THE TREATMENT OF INFANTILE PALSY.

During the febrile period we are to combat the fever by using 2 to 4 teaspoonfuls of the following mixture:

℞ Hydrochlorate of quinine, gr. viii;  
Syrup, ℥i;  
Peppermint water, ℥i.

Wrap the lower extremities of the child in moderately strong mustard-plasters.

In the paralytic variety we should apply every day a feeble continuous current of four to five milliampères along the vertebral column,

and this should be allowed to pass for ten or twenty minutes. The small doses of iodides may be given internally. Morning and night frictions and massage should be applied to the paralyzed muscles with saline douches, both hot and cold. Passive gymnastic exercises should be carried out, and care should be taken that by means of this exercise deformities are avoided. As the treatment progresses it is well to administer the lacto-phosphates.—*La Tribune Médicale*, June 17, 1894.

#### BONE-MARROW IN THE TREATMENT OF PERNICIOUS ANÆMIA.

FRASER, of Edinburgh, writes on this subject in the *British Medical Journal* of June 2, 1894, and, although this communication deals with only one case of pernicious anæmia treated with bone-marrow, the reputation of the writer and the curative effect seems sufficiently evident to justify its publication, especially as an opportunity occurred for testing in it the value of the chief remedies hitherto used in the treatment of this disease.

The patient—A. R., a gardener, sixty years of age—entered the Royal Infirmary on September 30, 1893. His symptoms were frequent vomiting and diarrhoea, oedema of the feet and ankles, moderate and irregular pyrexia, dimness of vision, retinal hemorrhages, anorexia, dyspnoea, and, latterly, complete prostration. The illness had existed for about four months.

Although the author was desirous to treat this patient at once with bone-marrow, the condition was so serious a one that, in the absence of experience regarding the therapeutic value of bone-marrow, he considered it advisable to administer, in the first instance, some of the remedies usually employed in pernicious anæmia. Only after they had failed in producing benefit was bone-marrow given.

For the sake of brevity the history of the patient is divided into eight periods, which correspond with the treatment adopted in each period.

First period, two weeks ; no medicinal treatment. During this period the hæmocytes of the blood varied from 1,860,000 to 1,460,000 per cubic millimetre, and the hæmoglobin from twenty-eight to thirty per cent., the specific gravity being 1038. There was great distortion in the shape and variation in the size of the hæmocytes, which did not form rouleaux. Retinal hemorrhages were present in both eyes.

Second period, two and a half weeks ; ferrous chloride, 6 to 12 grains daily. The hæmocytes and hæmoglobin steadily fell to 900,000

per cubic millimetre and twenty per cent. respectively, and the specific gravity to 1036.

Third period, eight days ; arsenic (15 to 30 minims of liquor arsenicalis daily) was given, in addition to 12 grains of ferrous chloride, daily. Still further deterioration occurred in the hæmocytes and hæmoglobin, the former falling to only 843,000, and the latter to eighteen per cent., but the specific gravity remained at 1036.

Fourth period, three weeks ; arsenic and iron were continued in the above doses, but ox-bone-marrow was now also given by the mouth, uncooked and in the quantity of 3 ounces, daily.

An almost immediate improvement occurred, so that at the end of this period the hæmocytes numbered 1,800,000, the hæmoglobin amounted to thirty-five per cent., and the specific gravity was 1042. The patient now began to recover strength ; he could remain out of bed for several hours each day, and the appetite was greatly improved.

Fifth period, twenty-six days ; ox-bone-marrow, arsenic, and salol (15 to 30 grains daily). The improvement was continued. The hæmocytes rose to 2,470,000, the hæmoglobin to fifty-five per cent., and the specific gravity to 1047. The patient felt much stronger, and his complexion was distinctly pink and had almost entirely lost its originally yellow hue. He had also gained in weight.

Sixth period, thirty-two days ; ox- and calf-bone-marrow and salol (30 grains daily).

The improvement was still further continued, so that the hæmocytes reached an absolute maximum of 4,130,000, though they afterwards fell to 3,400,000 ; the hæmoglobin rose with the hæmocytes to seventy-five per cent. and also fell to seventy per cent., and the specific gravity became 1058. The blood had now a healthy appearance. It could flow readily from a small puncture, it formed fairly good rouleaux, and the red cells were more uniform in size and fewer of them were distorted.

The patient was now able to do light work in the ward without fatigue ; the alimentary system was perfectly healthy ; oedema, pains, headache, pyrexia, and the venous bruits in the neck had disappeared, and the skin had a healthy appearance.

Seventh period, one month ; ox- and calf-bone-marrow and ferrous chloride (6 to 12 grains daily). The hæmocytes remained, with some oscillations, at about 3,400,000 ; the hæmoglobin averaged from seventy to seventy-five per cent., on one occasion reaching eighty per cent., and the specific gravity remained steadily at 1059.

The patient felt strong and enjoyed assisting in ward work, such as carrying coal up a long flight of stairs. He remained out of bed all day, there were no subjective symptoms even on considerable exertion, and "hæmic" venous and cardiac bruits were no longer audible. Ophthalmoscopic examination of the eyes showed that all traces of retinal hemorrhage had disappeared.

Eighth period, not concluded when this paper was communicated to the Congress; ox-bone-marrow, iron, and salol. The improvement was maintained, so that the hæmocytes reached 4,000,000, the hæmoglobin eighty-five per cent., and the specific gravity 1060. The patient was now practically in a normal condition. His appetite was good and his appearance that of a healthy man.

An examination of the graphic representation of the progress of the case shows that no benefit was obtained—that, indeed, deterioration occurred—during the prolonged administration of iron and arsenic in both medium and large doses, but that the remarkable improvement which occurred was produced only after the administration of bone-marrow had been commenced, while it continued to be produced during periods in which neither arsenic nor iron were being administered.

The demonstration of a curative influence by bone-marrow may appear to be somewhat obscured by the introduction of salol into the treatment, and a further examination of the therapeutic value of this substance in pernicious anæmia appears, indeed, to be suggested. The introduction of salol was due to the urgency of the case requiring that no description of treatment should be neglected in whose favor any theoretical or experimental evidence had been advanced. Since, however, this communication had been made to the International Medical Congress, the patient was treated with only bone-marrow for a period of twenty-seven days (period ten), and the improvement was well maintained to the end of this period.

He was discharged from the hospital because of his urgent wish to return to work as a gardener, for which he declared himself more able than he had been for the last five or six years; and, to use his own expression, he felt "as if he had been made over again." On the day when he left the hospital (May 19, 1894) the hæmocytes numbered 3,900,000 per cubic millimetre, the hæmoglobin was seventy-eight per cent., and the specific gravity 1058; the hæmocytes were nearly uniform in size, only a few of them showed slight "tailing" and no megalocytes were present; there was no excess of

leucocytes or of blood-plates, and good rouleaux were formed on the microscopic slide.

It may be worthy of note that before medicinal treatment had been commenced, and in the earlier periods of treatment when the patient was receiving large doses of iron and arsenic, the blood-plates were conspicuously deficient in number; while soon after the administration of bone-marrow had been commenced a great increase occurred in their number, which was followed by a reduction to a moderate number during the later periods when the blood had been restored to a nearly normal condition.

The frequent failure of therapeutic measures in pernicious anæmia confers an interest upon any remedy which appears capable of controlling this malignant disease, even although the evidence is derived from one case only, and notwithstanding the circumstance that temporary improvement occasionally, though very rarely, appears to occur spontaneously. The facts now stated appear to justify the hope that bone-marrow will be found to have a remedial value in some, at least, of the cases of pernicious anæmia.

#### *TINCTURA FERRI CHLORIDI IN TYPHOID FEVER.*

In the *International Medical Magazine* for June 1, 1894, is an article on this subject by McNUTT.

Many and various are the remedies that have been and are being used in the treatment of typhoid fever. It is not the intention of this abstract to discuss the hygienic and antipyretic treatment of this affection. The tincture of iron is useful for the gastro-intestinal condition, for its surface intestinal antipyretic action. It might be well to say, however, that antipyretics are used much too freely in typhoid, and greatly to the detriment of the patient. Too many practitioners are governed in the treatment by the thermometer. Better not use the thermometer at all in typhoid than to be steadily and surely beating the life out of the patient in vain efforts to break down the fever.

Typhoid fever is not a frequent disease in San Francisco, and consequently the number of cases that the physician is called upon to treat is not large; still, scarcely a year passes but every physician in San Francisco who has a large family practice meets with a few cases. In the course of twenty-five years the writer had an opportunity of trying all the so-called gastro-intestinal remedies, such as turpentine,

bismuth, salicylic and mineral acids, nitrate of silver, iodoform, copper, zinc, etc. For the past four years he has been in the habit of administering tinctura ferri chloridi in glycerin and water in nearly all these cases of typhoid fever, 10 to 30 drops every two to four hours.

McNutt's practice has been to commence the administration of iron as soon as positive indications of typhoid are recognized. The result of his experience is, that the tincture of iron is the most reliable of all gastro-intestinal remedies and much more efficient than the muriatic acid without the iron. It certainly exerts a beneficial influence on the mucous membrane by its astringent and tonic properties, limiting the hyperæmia, and consequently the exudations and tendency to ulceration and to hemorrhage. Besides the beneficial influences of tincture of iron on the mucous membrane of the digestive tract, it certainly has a sustaining influence, by acting as a blood food, in preventing waste of tissue, when there is very considerable diarrhoea or dry brown tongue, which is not often the case when the iron is given freely.

$\frac{1}{10}$  to  $\frac{1}{100}$  grain of bichloride of mercury to each dose is frequently useful, when the gastric symptoms are prominent, or liquor acidi arseniosi, 1 or 2 drops, sometimes adding both with benefit.

#### THE PREPARATION OF THE FINGERS AND NAILS FOR SURGICAL OPERATIONS.

ALLIS (*Maryland Medical Journal*, July 21, 1894) thus discusses the finger-nails from the stand-point of the operative surgeon:

The nails form no mean part of a surgeon's outfit. As a covering to the end of the finger they give confidence; in the threading of needles they are often indispensable; while often, when working among adhesions, they may serve a good turn. If the nails are too long, they are in the way, and if too short, a privation. A medium length of nail is an exceedingly valuable helper at times. With some the length of nail is governed by the ability to keep it clean; hence the nail is kept very short, much to the disadvantage of prehension, in which man excels.

The surgical care of the nails has had its full share of attention. The nail-brush forms a part of every physician's and surgeon's outfit. It is cheap, compact, and moderately thorough. Its disadvantages are, that if stiff, it is apt to scratch the hand or cut beneath the nails; if soft, it is of little value. To supplement the defects of the brush, some persist in using the point of the nail-blade of their pocket-knives. The

writer says persist in using, as much has been written against the practice. Not only is there danger of cutting the flesh beneath the nail, but it leaves the under surface of the nail rough, making it a ready collector of filth, and less easily cleaned for a subsequent operation.

To avoid the knife he uses a little wedge-shaped piece of soft pine. This, when wet, frays up, makes a kind of mop, is a good carrier of soap, and enables the user to wash out under the nail. The objection to this device is that the pine rapidly frays out, becomes bulky, and requires frequent trimming. Therefore the author employs a rubber eraser. A variety is made for artists and school-children that is wedge-shaped. This is ready for use as it is found at the stationer's, though if made a little sharper it is softer and more like a mop. It is pliable, soft, and an excellent carrier of soap. For the hand, generally the old-fashioned wash-rag cannot be improved upon. It is a good carrier of soap, and with it each finger in turn can be tightly caught and wrung until clean. With the nail- or hand-brush only the back and front of the fingers get the scrubbing.

In addition to the implements usually deemed important for the cleanliness of the under surface of the nails, a very valuable one is the nail itself. Noticing that a young lady's finger's whom he frequently met were always exceedingly neat, the writer made bold to ask her methods, and learned that she had nothing more modern than a pair of scissors to trim her nails, and that with wash-rag and the tips of her finger-nails she kept her hands in most perfect order. One thing that may be said of the finger-nail as a nail-cleansing instrument is, that it will not scratch the under surface of the nail, a very important factor in the process, whether one aims at beauty or cleanliness.

#### PERSONAL EXPERIENCE IN THE TREATMENT OF STRANGULATED HERNIA.

ASHHURST (*Kansas City Medical Index*, July, 1894) states that he has operated on twenty-one cases of hernia, nineteen of which were strangulated. He has reduced by taxis a number equal to that operated on. He holds that the comparatively small number of cases which he has to report shows that strangulated hernia is a rare affection in Philadelphia. Fourteen of the operations were for strangulated inguinal hernia; one case disappeared; of the remaining thirteen, ten recovered. Of the four strangulated femoral hernias, three recovered. The single strangulated umbilical hernia died. None

of the deaths were directly traceable to operation. In regard to the limitations of taxis, Ashhurst holds that this means of reduction should be the first, though in the hands of the inexperienced practitioner it is an unsafe procedure. Under such circumstances he believes the patient will sometimes be safer with the operation of herniotomy than with taxis. When taxis is employed, the neck of the sac is grasped by the thumb and fingers of one hand, while the other hand, spread out, exercises a combination of pushing and squeezing; and then by a kind of alternating movement, slightly relaxing one hand, while with the other the pressure is increased, if the hernia is reducible at all, it will go up. If no gurgling is heard in a few minutes, it is not likely that taxis will succeed.

As for aids in taxis, the hernia may be drawn down a little before beginning the upward pushing movements. In the Pennsylvania Hospital the practice is to put the patient in bed, apply ice over the hernia, and give a moderate quantity of opium. When the resident physician is not able to reduce the hernia by gentle taxis, this course is followed until the surgeon has been summoned. If slight manipulation on the part of the surgeon fails, ether is administered and taxis again employed in the ordinary manner, usually with success. If the hernia cannot be reduced, operation is resorted to, an understanding being had to this effect before etherization. When herniotomy is performed, Ashhurst follows the rule that where it is justifiable to resort to taxis, it is proper to endeavor to reduce the hernia without opening the sac. Frequently, the constriction being in the neck of the sac, it requires opening. In making the deep incision the tip of the left forefinger should be pressed against the source of constriction and the hernia-knife passed flatwise; this is then turned in the proper direction and the deep incision made with a gentle sawing motion, assisted by pressure of the finger below. In inguinal hernia the incision should be directly upward. In femoral hernia the deep incision should be made upward and inward, the hernia-knife being blunted by rubbing it on the handle of another knife. After operation the patient is put on the use of opium and belladonna for a few days, in gradually diminishing dose. Usually the bowels move spontaneously in five or six days.

was removed for cancer, with but one fatal result. The great majority of the operations were not complicated by removal of the lymphatic glands or ligature of the lingual artery. Nineteen of the patients were above sixty years of age, and some were suffering from organic disease of internal organs. All the operations were performed by Whitehead's method,—that is, a ligature is passed through the end of the tongue; this is drawn forward and loosened from before backward by small snips with a pair of long scissors. When the disease is situated wholly at the base of the tongue the lingual arteries are tied. Iodoform applied to the mouth by means of an applicator is best calculated to keep the wound in an aseptic condition. Wound secretions are prevented from gravitating into the air-vessels by keeping the patient's head low and letting him lie well over from the side from which the tongue has been removed. The feeding of these patients needs great attention. When not more than two-thirds of the organ has been removed, liquids can generally be taken on the day following the operation from a feeder with a spout, provided a piece of india-rubber tubing three or four inches long be fixed on the spout. If the right half of the tongue has been removed, the patient should lie over on the left side during feeding, so that the food is kept as far as possible from the wound, and passes over the parts which have been least interfered with.

When the whole of the tongue has been removed, the difficulty of swallowing is much greater, and many days may elapse before the patient acquires the knack of swallowing liquids without permitting a small quantity to pass down the air-tubes. During the first forty-eight hours these patients are fed through the rectum with nutrient enemata. At the end of that period the patient is allowed to make a first attempt to swallow a little liquid, and water is chosen for the experiment, because the entrance of a little water into the trachea is seldom followed by any serious consequences. Milk and beef-tea are more dangerous; they hang about the air-tubes, are difficult to get rid of, and are very prone to undergo rapid decomposition and occasion the much-dreaded swallowing pneumonia. If the experiment is successful, other liquids may be tried, and the problem of feeding is really overcome; but if there is any difficulty, the patient is fed as long as may be necessary through a tube. Butlin believes no instrument is so good for this purpose as a black bulbous catheter, about No. 9 or 10, attached to a long piece of india-rubber

#### REMOVAL OF THE TONGUE FOR CANCER.

BUTLIN (*International Journal of Surgery*, July, 1894) reports a series of forty-six consecutive cases in which at least half the tongue

tubing, to the other end of which a small glass funnel is fixed.

The throat is first sprayed with a three- or four-per-cent. solution of cocaine; the tubing is clamped with forceps just above the attachment of the catheter, and the funnel and tubing are filled down to the clamp forceps with warm food. The catheter is very gently passed down the pharynx, and hitches at the posterior border of the larynx. The patient is directed to swallow, and as he does so the catheter is easily passed on into the cesophagus. For the moment discomfort is created, and the patient often struggles. He is directed to close his mouth, and no attempt is made to pass the catheter farther down for half a minute or longer. Then it is slowly and gently passed down to a distance of about eleven inches from the teeth. When the annoyance of the presence of the catheter has ceased, the clamp is removed and the food is allowed to run slowly down into the stomach. If there is an inclination to regurgitation or to cough, the descent of liquid is instantly arrested by pressing on the tubing with the finger and thumb, and the nurse lowers the funnel until the dangerous moment has passed. By attention to these details a pint or a pint and a half of liquid may easily be introduced into the stomach without danger. Before removing the catheter the funnel is raised high up, so as to get rid of the contents of the tube, and during the actual removal of the catheter the tubing is kept tightly pressed between the finger and thumb in order to prevent the entrance of even a few drops into the larynx. When the feeding is carefully carried out according to these directions, Butlin has patients so satisfied with it that they have sometimes insisted on being fed through a tube for a much longer period than the writer deems necessary.

#### THE EARLY TREATMENT OF GONORRHEA.

After treating gonorrhoea for many years with silver solutions, DR. VON SEHLEN (*Monatshefte für Praktische Dermatologie*, June, 1894) formulates his experience in the following way: The duration of treatment depends upon the length of time of infection before handling the case; therefore the applications must be made as early as possible. In favorable cases, when the infection is not longer than four days, the case should be cured in one day.

In case of infection lasting eight days before treatment, three to six days are necessary for a

cure; infection of eight to fourteen days requires twenty days and upward.

The early treatment retards the progress of the disease along the urethra and lessens the course of the trouble, even when the gonococcus persists.

Despite the disappearance of the cocci, recurrence is not impossible, and careful watchfulness on the part of the patient is necessary while the gonococcus, through the silver applications, loses its growing energy.

In fresh cases, up to the third or fourth day after the infection, strong solutions (from one-fourth to one per cent.) of silver nitrate can be injected by means of the usual small syringe; the meatus being tightly held and the urethra being rubbed backward and forward, the solution reaches all the urethral mucous membrane. This is repeated until the mucous membranes are seen to be coated white with the silver precipitate, while the fossa receives a special application of a two-per-cent. solution, and is coated with euophen powder, which proves a good protector.

In cases of longer standing than four days, he applies, by means of the two-way catheter, feeble solutions (from .1 to 1 pro mille) in distilled water, warmed to the body temperature. The urethra soon becomes accustomed to stronger solutions, and after a few days the solution may be increased from one-fourth to one per cent, which can then be applied by means of the syringe.

#### TRIKRESOL AS AN ANTISEPTIC.

This antiseptic is a clear, colorless liquid three times as powerful as carbolic acid. It is cheap, makes a clear solution, does not corrode instruments, and neither makes the hands of the operator slippery like lysol nor numb like carbolic-acid solutions.—*International Journal of Surgery*, vol. vii., No. 3.

#### TREATMENT OF CEREBRAL HEMORRHAGE.

*Apoplexy*.—1. Loosen all tight linen; lay the patient down, with head a trifle elevated. Wrap the patient's arms and legs with sinapisms. Place a bag of ice under the patient's head. Vigorously rub the body with camphorated alcohol.

2. Administer the following purgative:

℞ Sodii sulphatis, ʒv;  
Sennæ (folliculis), ʒiiss;  
Aque bouillant., ℥ʒiiss.  
Make an infusion and strain.

3. If the pulse is not too feeble, give as soon as possible a hypodermic of a solution of ergotin (Dusort) containing fifteen grains.

4. If there is too much excitement, give two tablespoonfuls of,—

R Potassii bromidi,  
Strontii bromidi,  
Sodii bromidi, of each,  $\mathfrak{z}$ i, gr. xv;  
Glycerini,  $\mathfrak{f}\mathfrak{z}$ iss;  
Syrupus aurantii corticis,  $\mathfrak{f}\mathfrak{z}$ viss.

5. If the heart and pulse grow feeble, give from 1 to 5 hypodermics of sulphuric ether in the twenty-four hours.

6. Continue this treatment throughout the attack,—sometimes lasting several days,—and support the patient with milk and beef-tea, taken in small amounts.

*Period of Paralysis.*—1. Watch carefully the patient's mode of living; allow him to eat little at evening; food mostly vegetables, milk, eggs, soups, little meat; no alcohol or tobacco; no intellectual fatigue. Each morning sponge-bath of alcohol and water, followed by frictions with flannel. Watch carefully all pressure-points for bed-sores; order a water-bed, and dust the spots with a powder of cinchona and starch.

2. Maintain a loose condition of the bowels, and give the following pill every eight days:

R Aloes, gr. iiss;  
Rhubarb, gr. ivss.  
M. et div. in pil. No. 20.

3. Take during twenty days of the month a tablespoonful of the following solution in a glass of milk:

R Strontii iodidi,  $\mathfrak{z}$ iiss;  
Sodii arsenitis, gr. iss;  
Aque destillatæ,  $\mathfrak{f}\mathfrak{z}$ ixss.

4. Do not practise electro-therapy during the first months of the paralysis, but maintain massage regularly afterwards; commence with a feeble continuous current daily for twenty minutes.

*Prophylaxis.*—1. Those predisposed are counselled to rest in bed, without sleeping, after meals.

2. Upon rising sponge lightly with alcohol and water, with dry frictions afterwards and a short walk without fatigue.

3. Avoid sudden changes of temperature; intellectual fatigue or violent emotions.

4. Substantial but light food, white meats, fish, eggs, vegetables, fruits, but little dark meats; no alcohols; no shell-fish; don't rest too long at the table in a heated room, and take a walk after each meal.

5. Maintain regularity of the bowels, if necessary by means of salts.

6. During fifteen days per month take in a cup of milk a spoonful of the following:

R Potassii iodidi,  
Potassii bromidi, of each,  $\mathfrak{z}$ i;  
Aque destillatæ,  $\mathfrak{f}\mathfrak{z}$ ixss.

—*La Tribune Médicale*, June 21, 1894.

#### TREATMENT OF LEG ULCERS.

DIVER (*Medical Press and Circular*, quoted by the *Universal Medical Journal*, July, 1894) treats leg ulcers by means of chlorine gas. This is generated by pouring two drachms of potassium chlorate and one drachm of hydrochloric acid into a jar, the outside of which is covered with brown paper. After this a disk of white paper is introduced, and on top of the paper sufficient absorbent wool. A large cork is then fitted to the neck of the jar. The wool—yellowish-green on the surface when first exposed to view—is placed over the ulcer and quickly covered by gutta-percha tissue, kept in place by the ordinary bandages. The author reports rapid healing of chronic ulcers by this method.

#### RETAINED TESTIS.

KEETLEY (*Lancet*, quoted by the *Universal Medical Journal*, July, 1894) thus operates for retained testicles. After thoroughly freeing the gland from its fibrous attachments to the inguinal canal, it is brought down, and two skin wounds being cut in the scrotum and neighboring parts of the thigh respectively, these wounds, and some of the fibrous tissue always found attached to the testis or epididymis are sutured together, the sutures piercing the tunica vaginalis. The author has just operated upon two cases. In one the testicle distinctly grew after it was brought into its normal position.

#### CYSTICO-LITHECTOMY.

After seventy-seven operations upon the gall-bladder, in twenty-six of which he found impacted stones in the ductus cysticus, HANS KEHR (*Berliner Klinische Wochenschrift*, June 4 and 11, 1894) proposes incision of the cystic duct in all cases of impaction.

Formerly he performed the ordinary cystotomy, leaving a biliary fistula. After the lapse of a few months, when only mucus was escaping, he sounded this fistula, discovered a stone obstructing the backward flow of bile,

performed a second laparotomy, incised the duct, removed the stone, passed a drainage-tube through the duct,—now patulous,—and sewed the incision.

This plan he found open to the objection necessarily raised against a second laparotomy; also the sounding of the duct is not in all cases satisfactory nor safe. As a result of his varied experiences he has adopted the following plan:

Through a four-inch incision in the right rectus muscle he inserts his right hand, breaking gently all adhesions until the cystic duct is reached. He then searches for and finds the stone, and then endeavors to force it back into the gall-bladder, pursuing the method of Lauenstein. Standing on the patient's right side, the operator turns his back to the patient's face; then bending forward, he inserts the left hand into the abdominal opening and endeavors to force the stone from its impacted position. This seemingly clumsy position is, as a matter of fact, of the greatest value in this manipulation. This manoeuvre, however, failing, the gall-bladder is aspirated of as much of its contents as possible by puncture at the fundus, flat sponges are inserted to catch any remaining bile, the bladder is incised, the wound edges being held up by forceps, and the cavity of the bladder is cleaned by repeated packing with gauze.

The right hand now grasps the stone, the left index finger is passed into the bladder (a sound or forceps may also be tried), and by the combined manipulation an endeavor is made to move the stone in a backward direction. This plan failing, the bladder is sewn to the wound, and further proceedings arrested until swelling of the mucous membranes forces the stone into view; sometimes even then the finger or spoon or forceps are required for its removal.

If, however, he finds the stone very large or strongly embedded, he proceeds at once to the incision of the ductus cysticus over the point of impaction. The bile and stone are at once removed, drainage inserted, and the incision sewed together with fine silk and a curved needle. To facilitate this, he passes two loops of silk through the edges of the wound, and then, by further holding apart of the abdominal wound, lifting of the overlapping lobe of the liver, and tension on the two silk loops, the suture of the duct is much facilitated. He especially avoids sewing the mucous surface or including too much of the serous coat. The bladder is packed as before, and after the expiration of some time, both tube and packing being removed, and finding the duct patulous, he closes the external fistula.

#### TREATMENT OF COLLES FRACTURE.

DOYLE (*International Journal of Surgery*, July, 1894) advocates an ingenious, simple, and easily-constructed splint for the treatment of Colles fracture. Two or three thicknesses of cloth or flannel may be cut to the proper shape. These are then dipped in plaster-of-Paris cream and secured by a roller to the normal arm with the hand flexed slightly. After the plaster has set, it is removed and allowed to thoroughly dry. The fractured arm, which has been in the mean time reduced and dressed, is placed in this anatomically-made splint, which readily retains the bones in their normal position by the aid of a roller bandage, smoothly but not tightly applied, no posterior splint being required.

#### TECHNIQUE OF MAJOR AMPUTATIONS.

CREDE (*Medical Press and Circular*, quoted by the *Universal Medical Journal*, July, 1894) attaches little importance to the Esmarch bandage, avoiding a number of ligatures by doing without it. The form of the flap is also a secondary matter. The important point is to cut a flap lined with a thick muscular layer, as the muscles have a tendency to undergo ultimate retraction. He uses neither drainage nor suture, the edges of the flap being approximated by a gauze bandage applied directly to the stump in such a way as to make slight compression. In twenty-two cases thus operated on, all did well, two-thirds healing by first intention. In the other one-third, small areas of suppuration prevented rapid recovery, but in no case was there separation of the wound, as occurs frequently when the flap consists of skin only.

Gussenbauer is also in favor of abandoning drainage, but holds that only by sutures can exact approximation of tissues be obtained.

#### DR. HERON WATSON'S METHOD OF EXCISING THE WRIST-JOINT.

By this method the knife is entered about one and a half inches above the styloid process of the ulna, towards the palmar aspect, and carried down to the metatarsal bone of the little finger and a short distance along it. An incision of about three inches in length is thus made down to the bone. The lower end of the ulna is then cleared and fully an inch of it removed. The carpus is then exposed and removed piece by piece, the trapezium only being left. The heads of the metatarsal bones can then be dealt with by gouge or saw, being turned out of the wound if necessary. Next

the end of the radius is turned out, which can be quite easily done, and sawn off. Last of all the trapezium is examined, and removed if necessary. Each step in the operation is very easy and very satisfactory. After removal of the necessary amount of diseased bone, very few vessels require to be ligated. Sometimes one at the radial side of the wound is rather difficult to secure; but as the wound can be turned almost inside out by shoving the thumb in like the finger of a glove, no great difficulty should really be experienced.

MILLER (*Edinburgh Medical Journal*, August, 1894) advises as an after-dressing packing with iodoform gauze, which should be diminished in amount with each dressing. The hand and forearm should, of course, be kept at rest on a splint. Passive movement should be commenced not later than a week after the operation. The joints that are most likely to be stiff are the metacarpo-phalangeal, but these are generally very rigid before the operation is performed. They should be freely flexed and extended, as a preliminary step to the operation. During the last six years the author has excised the wrist by Dr. Watson's method ten times. In one case subsequent amputation was necessary; in one case amputation was advised, but not submitted to; in three more cases disease returned, necessitating scraping; while in the remaining half of the cases the disease did not return, and a useful hand was obtained. In the three cases that were scraped—one of them twice—a fairly useful hand resulted. An interesting fact in these recorded cases is that eight out of ten cases presented the right hand, which seems to point to trauma as the exciting cause.

The advantages of this method are that only one incision is necessary. Drainage is very efficient, the wound being on the side of the hand which is the lower in the position in which the hand is usually carried. The resulting cicatrix is hardly visible, and therefore the appearance of the hand is fairly natural after recovery. The operation is very easy of performance.

#### TREATMENT OF CANCER WITH METHYL-BLUE.

VON MOSETIG MOORHOF exhibited a patient suffering from villous cancer of the gall-bladder, treated with pyoktanin internally and locally. He introduced into the examination wound every two days a pencil of methyl-blue, and gave nine and a quarter grains in pills. The treatment resulted in complete cure.

#### VESICAL PAPILLOMA OF UNUSUAL DURATION.

WEIR records an interesting case of this order occurring in a man of fifty-two. Bleeding had persisted off and on for a period of thirty-seven years. The diagnosis was most satisfactorily made by the employment of Guyon's method,—*i.e.*, the urination of the patient into three glasses, in the last of which the most and freshest blood was found. After washing out the bladder a bimanual examination was made, the catheter being left *in situ*, by which manoeuvre fresh blood was pressed out in small quantities through the catheter, or else was washed out of the catheter after it was withdrawn. Cystoscopic examination failed to reveal the existence of the growth. The papilloma, about one inch and a half in length and a quarter of an inch in diameter, and quite fibrous in character, with fringe on its free ends, was situated just above and to the right side of the meatus internus urinarius. The tumor was detected in a very ready manner after the suprapubic section had been made, by the insertion of a large Ferguson's glass vaginal speculum. This idea has been suggested by Fenwick, of London, who used such a speculum as a sort of caisson, even with the bladder more or less filled with water or urine, in which case the speculum was to be passed to the deeper part of the bladder, the imprisoned water soaked or wiped out, and the bladder thus exposed carefully inspected. Weir, however, found it better to wipe out the bladder as well as possible, then introduce the speculum, and sweep it along the walls of the viscus. Through this same speculum the recorder seized the tumor with a forceps and with a curved scissors cut it off, and then with a Paquelin cautery lightly touched its bleeding surface, and finally packed upon the still bleeding wound a wad of iodoform gauze, which was held firmly in position until all hemorrhage ceased.

This operation commands a ready view of the whole of the bladder in its lower and posterior parts, which parts are most affected by growths. It enables one to readily recognize the mouths of the ureter, and to pass into them, if necessary, instruments for their further exploration.

The bladder in this instance, after removal of the tumor, was sewed snugly together and the abdominal wound left open. The patient made a prompt recovery, with a very trifling leakage for eight days, and has remained well. The tumor was a papilloma with a heavy fibrous stroma.

*INTERNAL URETHROTOMY FOR STRICTURE.*

SCHUMPERT (*Medical Record*, August 11, 1894) discusses the treatment of stricture of the urethra as follows:

It is a popular idea with the majority of the profession (prejudiced by results antedating antisepsis) that the cutting operation should be the last resort; that it should be used when all else has failed. The author gives a record of thirty-nine urethrotomies performed by himself, thirty-five of which were internal, including four impassable; the remaining four were external urethrotomies. The latter were among the first operations on the urethra in his experience; they were two with and two without a guide. He has since become so impressed in favor of the internal operation that he has never returned to the external. His experience with strictures proves that palliative treatment is vain, notwithstanding the patient has been taught to use the bougie himself once or twice a month. The patients neglect this measure. He finds that internal urethrotomy gives the best results and is justifiable in any case occupying the pendulous urethra. His method of operating requires a set of sounds, a bistoury, grooved director, and a set of bulbous bougies or urethrometer; this latter instrument is not essential, though it may often be used very conveniently in locating strictures and testing their extent. Schumpert uses a bistoury which has a perfectly straight shank seven inches long, with a blade extending from its point half an inch back, and presenting not exceeding one-fourth of an inch beyond the front surface of the shank; the back of the blade is exactly on a straight line with the back of the shaft, even to its point. His grooved director is seven inches long and fork-shaped, with the handle of the fork representing the groove of the director and the prongs the handle; it is made of sufficient strength to admit of considerable pressure without bending; the strength of the director, however, must not lie in its back, but sides only, as the back must be thin in order to allow the back of the knife to approach as nearly as possible the roof of the urethra, thus enabling the operator to incise the stricture through its entire diameter. The patient having been placed in the usual position and a stricture diagnosed, if it be meatal, surgeons all agree that it should be cut with a bistoury, and in this locality a director is not indicated; but if it be lower, this latter instrument becomes imperative. With the grooved director and bistoury described all pendulous strictures have fallen in the field of internal urethrotomy and

are easily accessible. The penis is held at right angles to the body with the left hand of an assistant, while with his right he holds the director firmly against the urethral roof, with the groove of the director presenting towards the patient's feet, the penis in the mean while being kept somewhat extended. If the stricture be passable, the operator passes the blade of the bistoury down the director until in the locality of the stricture, this point being marked by the thumb and second finger of his left hand, which press gently the sides of the corpora cavernosa; the index finger is held against the spongy body, directing the blade of the knife, which may be plainly felt as it cuts through the stricture, first in front, then on either side. If the stricture be impassable, the director is introduced until its blunt end comes in contact with the face of the stricture, the penis being held as before if the coarctation is in the upper pendulous portion; but if it is lower, possibly in the anterior membranous urethra, after the director and knife have been introduced beyond the suspensory ligament, the penis is tilted forward to an angle of about forty-five degrees, the director pressed firmly in the direction of the symphysis pubis and downward until in contact with the stricture; the knife is now pressed well back against the director, then downward until the resisting stricture yields; three incisions are then made as before described. The main points to bear in mind are, to have a reliable assistant, who will hold the penis and director perfectly steady and exactly as directed by the operator, who must himself see to it that the end of the director is in contact with the face of the stricture, that it is in perfect line with the penis, and must be very careful to pass his knife exactly in that line. After-treatment consists in first washing out the urethra with hydrogen peroxide, then injecting copiously with boracic-acid solution; this is done seven or eight times a day, until all discharge ceases. A large sound is introduced once in four or five days for the first month, once a week the second month, once in two weeks the third, and during the next two months twice or three times ought to suffice.

*THE OPERATIVE TREATMENT OF RUPTURED URETHRA.*

DEANESLY (*Practitioner*, July, 1894) completes a paper with the above title with the following statements:

In all cases where rupture of the urethra has been caused by direct violence, it should be the rule of surgery to perform primary urethror-

raphy. Cases not treated in this way almost always result in stricture. This form of stricture is so intractable to all forms of dilatation and division that during the last few years many surgeons have bodily excised the strictured portion and restored the continuity of the canal by suture. Undoubtedly this treatment has much to commend it. The stricture is usually a single one of very limited length and in most cases easily accessible. There is no difficulty in detaching the urethra from the corpora cavernosa sufficiently to allow the approximation of the divided ends. Lastly, the results obtained prove that a urethra of perfectly normal calibre, with no tendency to contract, can be obtained in this way and in no other.

Cases of ruptured urethra complicating fracture of the pelvis are very rarely capable of being dealt with by primary urethrorrhaphy. Indeed, it is not common for these cases to live beyond a few days. As a rule, nothing can be done in the first instance beyond providing against extravasation by perineal section. A secondary urethrorrhaphy might perhaps be possible in some cases after recovery from the fracture.

In conclusion, certain objections should be mentioned which are urged against the performance of urethrorrhaphy. It may be said that it is sometimes impossible to find the proximal end of the urethra, owing to its depth. In cases of rupture by direct violence, the rupture is always in front of the triangular ligament, and in a recent case of this kind no surgeon with a competent and practical knowledge of anatomy could fail to find both ends of the urethra. In cases of fractured pelvis or in secondary cases with tight stricture, perhaps complicated with sinuses and fistulæ, the difficulty may be great, but should not be insuperable. By prolonging the incision backward through a portion or all of the sphincter ani, and by detaching the anterior wall of the rectum, it is quite easy to expose the prostate, or even the base of the bladder. At this point it would always be possible to expose the urethra behind the stricture, and if necessary to open it and pass a sound forward.

Hemorrhage from the injured urethra, especially from the bulb, when this is injured, is generally free enough to somewhat embarrass the operation, but need not be alarming, as it is readily arrested by suturing the urethral wound. Extravasation of urine has often taken place before the case has reached the surgeon's hands. Recorded cases, however, prove that this is no bar to the success of primary urethrorrhaphy, even when twenty-four hours or

more have elapsed between the accident and the operation.

Lastly, the risk of producing a permanent fistula is extremely small. In the absence of stricture or some form of obstruction, it is by no means easy to produce a permanent urethral fistula, so great is its tendency to close. Certainly the insignificant risk of fistula is quite outweighed by the very grave risk of stricture when ruptured urethra is treated by ordinary methods.

#### INCONTINENCE OF URINE AND FÆCES CURED BY CIRCUMCISION.

ROSENBERY (*Medical Record*, August 11, 1894) reports the case of a child he was called to see with incontinence of urine and fæces. The child seemed to be as healthy as the average four-year-old. In making an examination the reporter discovered an elongated prepuce. The following day the child was anaesthetized and circumcision performed. At the time of the operation a digital examination revealed a patulous anus, with no sign of a sphincter muscle. When complete healing had taken place, the bowel-trouble entirely subsided, but there was still incontinence of urine. Finally, the physician advised atropine tablets, pushed till dryness of the throat was pronounced. The child fully recovered.

#### PRESCRIPTIONS.

For obstinate thrush in children :

R Zinci chloridi, gr. ii;  
Aque, ℥vi;  
Solve.  
To be applied locally.

For alopecia areata :

R Aceti cantharidis, ℥i;  
Unguenti hydrargyri oxidi rubri, ℥i;  
Misce et fiat unguentum.  
To be applied to the affected parts twice daily.

A pigment for warts :

R Acidi salicylici, gr. xv;  
Acidi lactic, m̄xv;  
Collodii flexilis, ad ℥ii.  
Misce et fiat pigmentum.  
To be applied morning and evening.

A cooling lotion for pruritus :

R Liquoris ammonii acetatis, ℥ii;  
Acidi hydrocyanici diluti, ℥i;  
Spiritus rectificati, ℥iii;  
Aque rosæ, ad ℥viii.  
To be applied locally.

*ICHTHYOL IN GYNÆCOLOGY.*

STORER (*Boston Medical and Surgical Journal*, August 2, 1894) concludes an article on this subject as follows:

While ichthyol is by no means the gynæcological panacea that some observers have claimed it to be, still, it has sufficiently approved value to deserve a very high place in our list of remedies.

While its chief action is to relieve pain, it does possess certain resorbent qualities which in some cases are relatively powerful.

Its use is unattended with danger or discomfort.

The use of the pure drug is generally more satisfactory and reliable than that of solutions.

It has not yet been proved that it has any gynæcological value other than as a local application.

*PRESCRIPTIONS.*

For neuralgia:

R Quinine valerianatis, gr. x;  
Tinct. sumbuli, ℥i;  
Extracti taraxaci, liq., ℥vi;  
Infus. cascariillæ, ad ℥ii. M.  
A dessertspoonful three times a day.

For croup:

R Tinct. ferri perchloridi, ℥i;  
Potassii chloratis, ℥i;  
Glycerini, ℥i;  
Aq. cinnamononi, ad ℥iv. M.

A teaspoonful every two hours to a child four years old.

For diarrhœa in infants:

R Acidi carbolici, gr. ii;  
Bismuthi subnitratiss, ℥i;  
Syr. acaciæ, ℥ss;  
Aq. menthæ pip., ad ℥ii. M.

A half-teaspoonful every two to four hours (for a child one to two years of age).

For tympanitis:

R Ol. terebinthinæ, ℥i;  
Ol. amygdalæ dulc., ℥ss;  
Tinct. opii, ℥ii;  
Mucil. acaciæ, ℥v;  
Aq. lauro-cerasi, ℥ss. M.

A teaspoonful every three to six hours.

—*Medical Press and Circular*, July 18, 1894.

*WHITE SWELLING OF THE KNEE.*

SCUDDER (*Boston Medical and Surgical Journal*, vol. cxxxi., No. 5) formulates treatment as below:

The treatment of this disease, which has

such a progressive, important set of symptoms, depends largely upon the period in the disease at which treatment is instituted.

The indications for treatment are local and general.

The general indication is to improve the nutrition of the patient by means of properly supplied fresh air, a nourishing diet, and the relief of conflicting disorders.

The local indications are to provide conditions favorable to the process of repair at the site of the disease, to prevent or to correct deformity, and to restore, so far as possible, the functions of the joint.

The local treatment may be classified into the non-operative or expectant; the operative,—erosion, excision, amputation.

There is an impression which seems to obtain in many quarters that, even with continuous rest, a tubercular joint never recovers, and that operative treatment itself, short of amputation, is of doubtful utility. It may be taken as an ascertained fact that the great majority of tubercular joints will recover if properly treated, with complete rest to the joint, and under good conditions of hygiene, sea-air, and nourishing diet.

If, after the palliative and mechanical treatment which secures absolute rest to the functions of the joint,—and this means not only rest from motion, but rest from every trauma,—if, after this careful mechanical treatment, some permanent abatement of symptoms does not occur, as well as evident diminution in the girth of the joint, as shown by accurate periodical measurement, operative interference is called for.

The length of time required in a trial of this palliative treatment should be decided by the condition of the case itself, but at least three months would seem to be sufficient for a fair trial. It is extremely important not to delay too long, for the operative procedures will be sorely handicapped if attempted late in the course of the disease.

Erosion of the knee-joint is the first important operative procedure to be instituted if the protective treatment fails. By the erosion of the knee-joint is understood the removal of diseased synovial membrane and ligaments, and, if necessary, also, to a very slight extent, of bone and cartilage.

The advantages of the operation are: there is no shortening; there is no deformity, other than the cicatrix; there is no arrest of the growth of the limb; free movement of the joint has resulted, although this is not always desirable. The causes of failure of this

operation are: incomplete removal of the disease; failure in maintaining asepsis; inability of the patient to repair the wound left by the operation. Prolonged care is required to prevent flexion of the knee. The leg must be immobilized for some time,—two or three years, or longer, if necessary. In properly selected cases it is safe to class erosion as an efficient surgical procedure.

If the knee is flexed, and has remained so for years, it is corrected by forcible correction of the deformity of flexion. The operation is performed by means of an apparatus purposely devised so that, without increasing the intra-articular pressure, the deformity may be corrected. Seven cases are reported, with good results in all.

Those cases should be excised which the expectant treatment, properly carried out, has failed to benefit, and in which erosion is contraindicated because of the extensiveness of the disease in the hard parts.

Amputation is necessary for those cases in which there exists disease too extensive for excision, and in which the general health is so poor as to demand immediate relief from the tremendous drain of prolonged suppuration.

There are several questions of importance to be considered in connection with the operation of excision of the knee-joint: the necessity of internal fixation; the method of operating; the external appliance to be used; the length of time for maintaining immobility. From a careful review of the experience of many operators, it seems that the accurate approximation of the tibia and femur secured by metallic sutures offers the best internal fixation,—better than that obtained by pins and other means.

The transverse incision through the ligamentum patellæ is most satisfactory, as it affords a more thorough exposure of all the joint surfaces than any of the other incisions suggested.

After the operation a rigid external support is necessary. For a long time—at least a year or more—the unprotected leg should not be allowed to receive the weight of the body. Immediately after the operation a proper protection is provided only where both the hip- and ankle-joints are immobilized. This is best accomplished by a plaster-of-Paris roller bandage extending from the tips of the toes upward and around the body at the hips.

The preservation of the patella is urged and discouraged by equally good authorities. The leg is stiff after operation; there is little use for the quadriceps, and its attachment to the patella, even if preserved, could be of little use. The bones are firmly united together. The pa-

tella, therefore, cannot help in retaining the bones in place. If there is any disease in the patella, complete removal of the bone is desirable, so that no portion of the disease may be left behind.

White swelling of the knee-joint is insidious in its onset, slow in its progress, and, if untreated, is sure in its ultimate results; its clinical course is varied. The indications for its treatment are constantly changing.

In many cases of white swelling of the knee-joint there comes a time when just as careful judgment is needed to determine whether mechanical means alone shall be depended upon, or whether operative interference is needed to insure the best results, as is required of the surgeon in the care of cases of appendicitis, where he is called upon to decide for or against operation. The immediate danger from an error of judgment is less in the former than in the latter cases, but the nicety of the judgment demanded is equally great.

The writer concludes his paper with the detailed history of thirteen cases on which he operated with uniformly beneficial results.

#### *IMPERMEABILITY OF THE EPITHELIUM OF THE HEALTHY BLADDER TO MEDICAMENTS AND POISONS.*

According to the correspondent of the *Medical Press*, July 18, 1894, at the last meeting of the Académie des Sciences, MM. BOYER and L. GUINARD made a communication on this subject. They undertook to demonstrate that the opinion of physiologists on this subject is perfectly justified, that the epithelium of the bladder possesses no absorbent power whatever when perfectly intact. The histological formation of the epithelium in question does not favor penetration, and one has only to think of the physiological rôle played by the bladder to be convinced of the error which those commit who believe in its absorbent power. A large number of authorities have put forth views similar to those of the author's, and these latter would not have reverted to the subject had not an opinion diametrically opposite been expressed by a distinguished surgeon (M. Bazy) before the Académie in November, 1893. The authors have demonstrated the truth of their opinion by experiment. Employing first the procedure of Cazeneuve and Lepine, they ligatured ureters and urethra in several dogs and injected into the bladder by means of a fine canula chlorhydrate of strychnine. In these conditions the animals tolerated during seven to nine hours, without the

least sign of poisoning, .02, .03, and .04 gramme of poison.

Wishing to operate under still more physiological conditions, they injected active solutions into the bladders of big dogs, *via* the urethra, by means of a catheter. Many animals being kept perfectly quiet, retained poisonous solutions for periods varying from eight to twenty-one hours. Metallic poisons, irritating substances, and those which give off fumes were not tried. Alkaloids alone were used, it being considered that among these agents there exist elements so poisonous and diffusible that when introduced in strong doses into the bladder they would surely produce rapid death if absorption really took place. Under the preceding conditions twenty-three experiments were made, and in all these not the least trace of any local or general physiological disturbance was noticeable, nor any indication of absorption of the alkaloids. Of these, pilocarpine, atropine and eserine, cocaine, morphine, veratrine, arsenate and chlorhydrate of strychnine in toxic doses were injected.

On every possible occasion the presence of the poisons in the voided urine after the experiments was ascertained, and a control experiment was also performed.

The urine from three dogs which had retained in their bladders .10 gramme of arsenate of strychnine was collected. After concentration this urine was injected hypodermically in two instances into the dogs which furnished it, and in the third instance into several frogs, two guinea-pigs, and a rabbit. All these died with classical signs of strychnine-poisoning.

The authors believe that the mucous membrane of the bladder, when inflamed, permits absorption, and they found death to follow injection of the poisons named when inflammation existed.

#### TREATMENT OF LATERAL CURVATURE OF THE SPINE.

MCKENZIE (*Medical Press and Circular*, July 18, 1894) gives an interesting *résumé* of this subject, with some valuable therapeutic suggestions.

The causation of this deformity is a subject of the utmost importance, because, were this fully known and did it receive due attention, much could be done to prevent what is a very common, distressing, and intractable affection.

1. Difference in length of the lower extremities. Recently authorities have been inclined to lay but little stress upon this asymmetry as a cause, but in the observation of the writer it is

a very common cause. A considerable number of the cases observed had suffered from infantile paralysis, which had left one lower extremity shorter and weaker than its fellow. As a consequence, the pelvis on that side drooped constantly when standing or walking. In this manner the plane of the base of the sacrum was inclined to the affected side, and a lateral curve of the lumbar vertebræ to the same side resulted. This is almost invariably accompanied by a compensatory curve to the opposite side; higher up in the spine. Sometimes a third curvature is observed, compensatory to the second. Often the extremities are found of unequal length when no definite cause can be assigned for this condition. Whatever the cause of the inequality in the length of the extremities, it is reasonable to consider it as strongly predisposing to lateral curvature.

2. There may be an obliquity of the plane of the base of the sacrum when there is no difference in the length of the extremities.

3. An attitude of curvature at first assumed voluntarily may become habitual. A school-girl may carry her books under her arm; may habitually take a wrong position at her desk, or in other ways take an attitude that inclines to one or the other side. This soon becomes habitual; the girl is more "at home" in the false attitude than she would be when erect, and the muscles, ligaments, and even bones of the side of the concavity soon adapt themselves to the new position and become shortened. In this manner an element of permanency is introduced in a case that, at first, was a wrong attitude voluntarily assumed.

4. Constitutional conditions, such as rickets, may act directly in causing unequal development, or may simply cause a weak spine, which readily departs from the vertical because of the pressure of the superimposed weight.

5. The great prevalence of lumbar curves to the left and of dorsal to the right goes to show that the greater use of the right hand and arm is a causative factor.

6. Unequal development of the two sides of the body from obscure causes may be assumed to affect the spine as well as the extremities, and thus become a direct factor in producing curvature.

A very important element in the deformity and the one most difficult to treat is the rotation or twist which occurs in the spine. The signs of curvature most noticeable and most readily appreciable by the inexperienced are inequality of the shoulders, of the angles of the scapulæ, of the hips, and of the ileo-costal spaces, and a departure of the row of spinous

processes from the vertical; but the deviation of the bodies of the vertebræ to the right or left always antedates the curvature, as seen on the surface and indicated by the spinous processes. Their deflection is also much more in degree than that of the spines. This increased distance of the bodies from the centre line causes a rotation about the vertical axis, and the head of the ribs and the first part of the shafts are thrown backward on the side of the convexity, while on the side of the concavity there is a corresponding flattening. In order that the ribs may meet at the sternum, there is a consequent sharp bending in front of the ribs that are flattened behind and a flattening in front of those which are more sharply curved behind. This gives us the marked inequality in the oblique diameters of the chest. This deformity is more common in girls than in boys, and most frequent between the ages of five and fifteen. The tendency is to become worse unless means are adopted to check its advance. Treatment of the constitutional conditions is, of course, of importance. The use of braces, splints, and jackets is to be discountenanced because of many objections. In cases of slight deformity it is difficult or impossible to apply any instrument that will grasp the deformity and hold it in a position of rectification. If it succeeds in doing so, it can only be by an amount of pressure which produces atrophy in parts already weak, and the more so because the pressure must be unintermitting. It more or less interferes with the functions of respiration and circulation, thereby retarding the general development, a matter of the greatest moment in these cases. Further, the patient learns to lean upon the support instead of on her own muscles.

A certain proportion of cases can be satisfactorily treated by gymnastics alone. If the case be one arising from habit, and if, when instructed, the patient can assume the erect position, or can produce considerable improvement by her own efforts, then much good may confidently be looked for from systematic gymnastic treatment.

The hearty co-operation of the patient is essential to successful treatment. All work done should centre about the one idea of assuming and maintaining the most erect and symmetrical position possible. When she has learned how to assume an improved attitude, little good will result, unless her confidence has been gained to such an extent as to insure her continued effort to maintain her bettered position.

The drill given should be daily, if possible,

and continued for several months. Several drilling together may be made to stimulate each other to greater efforts, and the improvement effected by certain movements in any one of the number may be witnessed by the others, and becomes a source of encouragement under circumstances where the daily drill is liable to become irksome and monotonous.

Much may be accomplished in the re-education of the senses of the patient, and much to encourage by having the improvement that is possible by personal effort shown while standing in front of a large mirror. If practice is taken in her own room and alone, in the interval between the regular drills, it should be done in this way, so that faulty positions may be avoided. At all times, whether in class or not, no exercises should be permitted until the ideal attitude for each patient has been assumed. The results to be looked for are not dependent so much upon the individual exercises performed as upon the manner of their performance. Whatever the particular movements which are prescribed, if they be executed while standing, sitting, or lying in faulty positions, these wrong attitudes are but confirmed. From time to time the patient should be carefully examined and assisted in assuming the best possible position, and afterwards this ideal attitude should be insisted on. The surgeon must have sufficient resource, sufficient knowledge of the work of the different groups of muscles, must have enough tact to originate and select such exercises as will accomplish most for each individual patient. It is also necessary that he should be able to execute all the movements gracefully himself.

Gymnastics alone will fail in exerting much corrective powers over a large proportion of cases. Since the pressure-correction exerted by braces has been so generally condemned, methods have been employed for exerting great corrective pressure for short periods of time. The author permits the patient to suspend himself by having a strap comfortably adjusted so as to grasp the occiput and lower jaw, having this connected by a cross-bar with a rope passing over a pulley and reaching to the hands of the patient. While he thus suspends himself some distance from the floor, a girth is passed around the body and connected with another rope passing over a pulley and controlled by the surgeon. This girth is so adjusted as to make pressure in the oblique diameter of the thorax in the direction that is found to be most effective in lessening not only the lateral curvature, but also the rotation. At the same time the circumstances are favorable for

using pressure with the hands of the surgeon in such a manner as to untwist the distorted spine.

This may be done for a period of ten minutes every day, or several times a day, with the result of producing much greater suppleness of the trunk. This powerful stretching of the tissues in the concavity of the curve, moreover, becomes a very effectual means of giving massage to the deep-lying structures of that side, and, though weeks or even months may be required to obtain the utmost results possible, yet in a very short time it will be seen that the patient can voluntarily keep the spine in a more extended position.

When there is disparity in the length of the lower limbs, or from any cause an obliquity of the plane of the base of the sacrum, a "lift" should be applied, so as to bring the pelvis to the horizontal.

The maintenance of a perfect correction may be looked for in only a small percentage of cases, but much improvement may be effected in all. For this developmental method of treatment, as compared with the treatment by braces, it is claimed that,—

1. It is more effective in correcting deformity.
2. It results in very marked improvement in the chest development and in general health.
3. It greatly improves the tone, size, and power of all the trunk muscles.
4. It re-educates the sense of erectness, so that the patient can appreciate the difference between an erect attitude and a distorted one.
5. It gives the patient confidence, and puts into her possession the means by which she may not only retain the degree of improvement effected, but may continue for years afterwards to make still more improvement.

#### EXCISION OF THE WRIST-JOINT BY A NEW METHOD.

MYNTER (*International Journal of Surgery*, August, 1894) details the following method, which he has adopted with very satisfactory results:

Professor Studsgaard, of Copenhagen, advocated a complete splitting of the foot from before backward, in order to gain free access to the diseased focus in the anterior tarsal and posterior metatarsal bones. Incidentally he recommended a similar splitting of the hand for tubercular osteitis of the carpus, making a longitudinal incision between the third and fourth metacarpal bones, and thereafter open-

ing up the joints between the os magnum and unciform bones and between the semilunar and cuneiform bones. Both superficial and deep palmar arches are, of course, severed, and must be ligated in the wound. Mynter follows this procedure, with the exception that he splits between the second and third metacarpal bones, and then enters between the trapezoid and os magnum and between the scaphoid and semilunar bones, as by this incision the hand is more evenly divided in two. He made the dorsal incision reach up to the radius, but found it unnecessary on the volar side to extend the incision farther up than to the base of the thenar eminence. The annular volar ligament was, therefore, not severed. By careful dissection from the dorsal side and forcible separation he found it easy to avoid injuring the dorsal tendons and the large volar tendinous bursa.

The whole carpus could now be widely opened, and it was extremely easy with scissors to extirpate the two halves of the carpus, and with a fine saw to remove the surfaces of the radius ulna and the metacarpal bones. The wound was thereafter sutured, but in order to produce strong and healthy granulations, which secondarily might contract and form fibrous tissue, he packed the large cavity with iodoform gauze, let out through the upper part of the wound on the volar side. The patient got up on the second day and the wound healed by first intention. The gauze packing was removed once a week for seven weeks, and when then omitted the wound healed promptly.

#### GASTROPLICATION.

Under this name, DR. JOSEPH BRAND (*Oest-Ungar. Centralbl. f. d. Medicin. Wissensch.*, No. 14) has recently described a new operative procedure for the treatment of gastric dilatation. Although devised as long ago as 1889, it was not until February of this year that he had an opportunity of putting it into practical execution. Gastric dilatation is usually due to some form of stenosis at the pyloric orifice, either resulting from new growths, cicatricial tissues, or adhesions, and the aim of surgical procedures has been the removal of the cause of the obstruction. Much has been accomplished in this direction by the exsection of the cicatricial tissue or by resection of the pylorus, and the surgeon can point with pride to the successful results obtained in many of these cases by operative means. There are some cases of gastrectasia, however, in which,

after all medical treatment has been exhausted and laparotomy has been resorted to, none of the above lesions can be discovered, and the operator is obliged to close the abdomen without having made an effort to relieve the dilatation. It is for this class of patients that Dr. Brand recommends his operation, which has for its object the diminution of the size of the stomach by the formation of a fold and suture of its peritoneal and muscular layers. This procedure has been successfully performed in the case of a female patient suffering from extreme dilatation of the stomach, according to the following technique: The abdomen was opened by an incision eight centimetres in length and parallel with the border of the ribs on the left side. The stomach was then sought for, everted by slow traction, and the pyloric region carefully examined. No tumor, cicatricial deposit, or adhesions could be discovered at this place, but a distinct flexion had resulted in consequence of the sagging down of the greater curvature. The anterior stomach-wall was then folded inward and sutured in a transverse direction, and to the right and left of the transverse fold a longitudinal fold was formed in like manner. The same proceeding was carried out on the posterior gastric wall, which was rendered accessible by making several slits through the great omentum, through which the organ was drawn. It was found easy to lift the muscular and peritoneal layers from the mucous membrane, which could be felt as a thick seam. Over two hundred sutures of catgut and silk were inserted, and the stomach was then returned to the abdominal cavity. Aside from the wounding of an arterial twig of the arcus vasculosis during the insertion of sutures in the posterior gastric wall, no accidents were encountered during the operation, which was followed by a most rapid recovery.—*International Journal of Surgery*, August, 1894.

#### COMPOUND FRACTURE OF THE ANKLE-JOINT.

BALCH (*Boston Medical and Surgical Journal*, August 30, 1894) reports five cases of compound fracture of the ankle-joint treated in the Massachusetts General Hospital. They are of interest from the fact that very good results were obtained in cases which seemed to offer little hope of a useful foot when first seen in the accident-room. In one case there was a compound fracture of both ankles and a simple fracture of the thigh; in another, a compound fracture of the ankle and a compound fracture of the other thigh; in another, a compound fracture

of one ankle; and in the last, a simple fracture, becoming compound later from sloughing of the skin over a prominent portion of a dislocated astragalus.

We may draw the following conclusions from this series:

1. That, at any rate in the case of poor patients, it is worth while to try to save the leg, even when the ankle is so severely injured that the chances of a movable joint appear very small. To a poor man the appearance of the ankle and the slight lameness caused by some loss of motion in the joint are of little importance in comparison with the expense and trouble of an artificial leg.

2. That a very good way of treating these fractures is on a posterior wire splint. This splint allows us to easily adjust the fragments from time to time, as the swelling goes down, while the foot is held firmly in the right position.

3. That the best dressing is the dry dressing of sterilized gauze, with iodoform gauze for drainage, when necessary. In certain cases a wet antiseptic dressing will hasten the separation of sloughs; but, as a rule, the dry dressing is to be preferred.

#### RATIONAL TREATMENT OF APPENDICITIS.

ASHTON (*Denver Medical Times*, August, 1894) holds that it is impossible, with our present means and methods of diagnosis, to know the nature of the pathological changes taking place during the course of an attack of appendicitis.

That all forms of appendicitis are dangerous to life, as it has been demonstrated that germs pass through the walls of the appendix without the presence of either ulceration or perforation.

That surgical interference is indicated in primary and secondary attacks of appendicitis, so soon as the diagnosis is clear.

That surgical interference is not advised during an acute attack of appendicitis, except when grave symptoms intervene, unless a competent surgeon is at hand. Under these circumstances the case should be operated upon after the so-called recovery.

#### TREATMENT OF CHANCRE WITH PEROXIDE OF HYDROGEN SPRAY.

This treatment, according to WORSTER (*Denver Medical Times*, August, 1894), not only relieves the anxiety of the patient and places him

in a delightful buoyancy of mind, but cures the chancre in the shortest possible time, without pain or detention from business, and with less scar and less destruction of tissue than any other method. He then details three cases of the large Hunterian variety, embracing the worst forms of sloughing and phagedena.

The pressure of the spray (sixty pounds), which is one of the most important factors in the whole method, not only cleanses and produces thorough asepsis, killing the germs of the disease at the very bottom of the ulcer, but the oxygen of the peroxide aerates the blood through the capillaries and arrests the progress of the disease at the nearest possible point, allowing the process of repair to commence as soon as possible, with the least loss and destruction of tissue and consequent scar. It must be particularly understood that in using this treatment all instruments, spray-tubes, and bottles must be made of either glass or hard rubber, for the reason that metals, with one or two exceptions, coming in contact with the peroxide will destroy its component parts and render it useless. The first effect of a spray of peroxide upon the ulcer is to deposit upon it a thick film of albumin; this should be allowed to remain for about half a minute or less; then the spraying is continued until a large tubeful has been used (one ounce). As the sore progresses the spraying causes a good flow of rich arterial blood upon it, which merely shows returning healthy conditions.

The treatment is entirely painless, and the patients do not experience any annoyance or inconvenience whatever.

No internal medication during this stage is given. The iodol powder is used only as an antiseptic, to protect the sore from external influence until it is sprayed again the next day.

#### ATONY OF THE INTESTINE.

FRIEDENWALD (*Medical News*, August 11, 1894), after a careful *résumé* of this subject, advises the following measures:

The treatment of intestinal atony depends upon its cause. If the condition is secondary, the treatment must be directed to the primary disorder.

Chronic constipation is the symptom that occasions most annoyance, and special attention must be directed to it. In all uncomplicated cases of atony of the colon the condition can be successfully relieved by simple measures. The hygienic and dietetic treatment is highly important. Inasmuch as sedentary habits predispose to this disorder, exercise is of some value

in many cases. This should consist in walking, as well as in gymnastics in which movements of the trunk play a prominent part.

Such foods are ordered as stimulate intestinal peristalsis. In this class are included substances that furnish a large quantity of undigested residue, such as fruits, vegetables, salads, Graham and rye breads. When there is no special contraindication (such as gastric atony), large quantities of cold water taken before breakfast may be serviceable.

There are certain natural mineral waters which are sometimes of great value in the treatment of intestinal atony unaccompanied by atony of the stomach; the Glauber salt waters belong to this class. The waters of Marienbad are considered of great value in this class of cases, especially in the obese; but the saline waters—Kissingen Rokoczy—are sometimes preferable. However, as many cases of intestinal atony are accompanied by atony of the stomach, the use of large quantities of water in these cases should be very restricted.

Persons suffering with intestinal atony should avoid the use of food that tends to constipate. In this class may be especially mentioned red wines, tea, and rice.

The systematic employment of abdominal massage is of great value. There are but few uncomplicated cases of intestinal atony in which the constipation does not yield to this form of treatment. In very persistent cases the manipulation must be practised daily, or on alternate days at least, for from eight to twelve weeks. To be effectual the movements must be deep.

Abdominal massage is much assisted by electricity; by the external application of moderately strong faradic currents good effects are usually obtained; or the faradic current may at times be applied internally, one electrode being placed in the rectum, the other on the abdomen. When the galvanic current is used, the rectum is filled with water before the negative pole is introduced, the positive pole being placed upon the abdomen.

In cases in which massage and electricity cannot be employed, excellent results are frequently obtained by injections of large quantities of oil, as recommended by Fleiner. When the conditions insisted on by Fleiner are fulfilled, the injections rarely fail. In a large number of cases in which the author has employed these injections for the treatment of this form of chronic constipation, they rarely proved unsuccessful. The regulations to be fulfilled are: 1. Only the very purest oil should be employed; olive oil is the best. 2. Large quantities of the oil (from 10 to 15 ounces),

heated to the temperature of the body, must be injected while the patient is resting on the back with the pelvis raised. 3. The injections must be given carefully and slowly, so that no air enters the colon. When air is introduced severe colicky pains are frequently produced and the oil is immediately ejected. 4. The oil must be retained in the bowels for several hours; for this reason it is best for the patient to remain in the reclining position for several hours after the injection has been given.

When the injections of oil and the other methods just mentioned cannot be employed, injections of other fluids, such as warm water, cold water, glycerin, may prove serviceable. The introduction of glycerin suppositories into the rectum, or the application of powdered boric acid to the mucous membrane of the rectum, sometimes gives relief.

The employment of cathartics is in most cases to be deprecated. Inasmuch as patients become quickly habituated to remedies of this kind and their effects gradually wear away, larger and larger doses become necessary. When cathartics must be given, the simplest are the best; and the various preparations of cascara sagrada probably head the list. Pills of strychnine sulphate, or the extract of nuxvomica with belladonna, are to be highly recommended, as tending to strengthen the relaxed condition of the bowels.

#### AMPUTATION IN OLD CASES OF INFANTILE PALSY.

In a monograph upon this subject (Thèse de Lyon, *Lyon Médical*, July, 1894), CÉSAR insists that operation would be of great benefit in many cases, from the complete uselessness of the affected members.

The following are the conclusions with which he concludes his paper:

1. The functions are interfered with.
2. They are the seat of lesions, such as trophic ulcers, arthropathies, multiple fractures, etc.
3. Following Poncet, he proposes amputation, justifying it by the functional impotence and nutritive disorders.
4. Amputation is especially applicable in the lower extremity, where the application of an artificial member permits of easier and better walking.
5. In the case of double atrophy of the lower limbs, double amputation (the one following at some interval after the other) will allow the patient a better chance to move about than with two useless limbs dragging after him.

6. Amputation of paralytic arms is often indicated, and the proper use of asepsis renders operation through unsound tissues less dangerous than formerly.

#### TREATMENT OF HEREDITARY SYPHILIS.

Under the head of "Direct Treatment," SIMON (*Revue Internationale de Bibliographie Médicale*, July, 1894) recommends for an infant of five to six weeks:

Liqueur de Van Swieten, gtt. xx.  
Four times a day in milk.

Simultaneously inunctions morning and evening of unguentum Neapolitanum,  $\frac{1}{2}$  to 2 grammes.

This treatment is continued for five to six months, after which the mixed treatment is presented.

Syrupus Gilberti,  $\frac{1}{4}$  to  $\frac{1}{2}$  a coffeespoonful in water.

For baths:

Sublimate, 2 grammes;  
Alcohol, 30 grammes.

For a bath of a quarter of an hour:

Bichloride of mercury, 4 grammes;  
Hydrochlorate of ammonium, 6 grammes;  
Water, 2500 grammes.  
Taken in a wooden bath-tub.

For "indirect treatment," when the mother or the nurse cannot be medicated, then apply mercurial frictions or administer potassium iodide to a goat or a jenny, and use the milk.

"Local treatment" for mucous patches: touch with solid nitrate of silver, iodoform, or calomel.

For ulcerations:

Corrosive sublimate, .25 gramme;  
Warm water, 100 grammes.

For osseous tumors, apply the plaster of Vigo. Separation of the epiphysis should be treated by fixation of the fragments. If the separation is complete, remove surgically as a foreign body.

#### DOUBLE CASTRATION FOR ENLARGED PROSTATE.

EKLUND (*Revue Internationale*, July, 1894) relates two cases reported by Raum ("Transactions de la Société Médicale de Christiania," January 17, 1894), in which cystitis persisted, and which disappeared like magic after the

removal of the testicles. The hypertrophy of the prostate decreased immediately.

#### ERYSIPELAS IN CHILDREN.

TORDEUS (*Therapeutische Blätter*, July, 1894) applies locally compresses saturated with,—

R Spirit camphor., 1000;  
Hydrarg. chlor. cor., .05.

Internally a solution of antifebrin and resorcin, in doses of as many centigrammes of antifebrin as the child is years old, and of resorcin twice as many centigrammes as the child is years old. This solution is given three or four times a day.

#### GONORRHOEA OF THE UTERUS.

In the *Centralblatt für Gynäkologie*, R. NOCH (*Therapeutische Blätter*, July, 1894) proposes the following salve:

R Alumnoli, 7.5;  
Lanolini, 100;  
Aque dest.,  
Glycerini, of each, 25.  
M. et ft. unguentum.  
Sig.—Inject every three or four days.

### Reviews.

A TEXT-BOOK OF PRACTICAL THERAPEUTICS, WITH ESPECIAL REFERENCE TO THE APPLICATION OF REMEDIAL MEASURES TO DISEASE AND THEIR EMPLOYMENT UPON A RATIONAL BASIS. By Hobart Amory Hare, M.D. Fourth edition, thoroughly revised and enlarged.

Philadelphia: Lea Brothers & Co., 1894.

The following is part of the preface to the fourth edition of Dr. Hare's book:

"The fourth edition of this work having been called for in less than four years after the appearance of the first, the author has taken advantage of the opportunity to rewrite and add to many of the articles on drugs, remedial measures, and diseases, and to insert practical information concerning the value and prescription of the really useful remedies. Articles on methylene blue, chloralose, pyrogallol, condurango, convallaria, duboisine, and other remedies have been added to the part of the work dealing with drugs. In the part dealing with remedial measures other than drugs articles have been written on hypodermoclysis and enteroclysis, lavage, and upon mineral springs and climatic treatment. The latter article is

not intended to be exhaustive, but to give the general practitioner an idea of the therapeutic value of certain well-known resorts, in order that he may offer rational advice to his patients as to where they should go in search of health. Several new articles in the part devoted to the treatment of individual diseases have been inserted, and new or modified applications of the older remedies carefully noted throughout the entire book.

"In addition to these changes, the work has been revised in such a way as to render it uniform with the new U. S. Pharmacopœia. As that authority directs the use of the metric system, the doses of all drugs are given in both apothecaries' and metric weights, thus, 15 to 30 grains (1.0–2.0), so that the physician may conveniently use either system.

"It is hoped that this new edition will prove even more useful than its predecessors to the doctor who needs a book for ready reference in daily practice."

THE PHARMACOPŒIA OF THE HOSPITAL FOR DISEASES OF THE THROAT. Fifth edition.

Philadelphia: P. Blakiston, Son & Co., 1894.

This book contains the formulæ employed in the Throat Hospital in Golden Square, London, which was founded by Morell Mackenzie. Those who are called upon to treat this class of cases and who desire set formulæ will doubtless find this work of very considerable value. It has been carefully edited by Mr. Harvey, one of the surgeons to the hospital.

INEBRIETY OR NARCOMANIA: ITS ETIOLOGY, PATHOLOGY, TREATMENT, AND JURISPRUDENCE. By Norman Kerr, M.D., F.L.S. Third edition.

London: H. K. Lewis, 1894.

No practitioner of medicine goes through a year of professional life without having his attention called more or less directly to the treatment of inebriety in one of its forms. Not only is this true, but some of the most puzzling questions which he is called upon to decide arise in the treatment of this class of cases, for he is not only consulted by the patient, but by the patient's friends, who desire to know what the relationships may be, legally and morally, between themselves and the person who is affected. In addition to discussing his subject in a truly scientific and practical manner, Dr. Kerr has added very greatly indeed to the value of his book by his chapters on "Inebriety in its Medico-Legal Aspects," in which both English and American jurisprudence has been carefully studied, and the facility of ready

reference has been increased by a summary of each paragraph in heavy black letters set in the side of the text. The book is in every aspect to be highly commended, and is peculiar in the fact that it is of equal value to the specialist in the treatment of this class of cases and to the ordinary practitioner. While many of the prescriptions are somewhat more complicated than we would recommend theoretically, they all possess the advantage apparently of having had practical application.

**A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE.** By Austin Flint, M.D., LL.D. Seventh edition. Thoroughly revised by Frederick P. Henry, A.M., M.D.

Philadelphia: Lea Brothers & Co., 1894.

Among the large number of new books upon the practice of medicine which have been presented to the profession within the last few years, there is none which will stand better in the present or in the future than the seventh edition of this book, which has done as much for the reputation of American medical literature as any other single volume which any author has produced. It has been a characteristic of Dr. Flint's book, in its original form and under its various modifications produced by different revisers, that its description of clinical cases and of the practical side of disease has been always wonderfully true to life, and it is not surprising that this characteristic has not only been preserved, but added to by the careful editorial work of so conservative yet progressive a physician as Dr. Henry. Further than this, we think that the profession is to be congratulated that the publishers, in obtaining an editor, chose one so peculiarly well qualified to revise and bring up to date those articles in connection with which the greatest progress has been made in medical study, for Dr. Henry represents at once that side of professional life which appreciates all that which is good and at the same time is not so optimistic as to swallow in addition much that is bad. As the editor well says in his preface, he has constantly borne in mind the maxim, "Hold fast to that which is good," and in so doing has held fast to nearly all. Of the changes in this volume, we note that the chapters on Pathology have been very properly taken out, as pathology is now a subject which must be considered by itself. Among the new articles are ones upon Pulsating Pleurisy, Weil's Disease, Syringomyelia, Influenza, Hereditary Chorea, and a number of others, while the chapter upon Dyspepsia has been entirely remodelled on a modern basis; there are also good articles upon Amœ-

bic Dysentery and Amœbic Abscess of the Liver. We believe that the profession, the teachers, and the students of the country will appreciate this renovated volume as being one of the best, if not the best, all-around textbooks of the subject which they can obtain, and we congratulate Dr. Henry upon the successful completion of a task which was proportionately great with that of the reputation of the author and of his text-book.

**ANÆSTHETICS AND THEIR ADMINISTRATION.** By F. W. Hewitt, A.M., M.D., Cantab. Illustrated. London: Griffin & Co., 1893.

Notwithstanding the date on the title-page of this book, it has just been received for review. No one who reads its pages can fail to be impressed with the fact that Dr. Hewitt has brought to his pen the results not only of wide personal experience, but of a thorough knowledge of most of the literature connected with the important subject of anæsthesia. We note, however, in a number of places that he has failed to quote the most recent studies upon this important topic. The only reference that we find to the praiseworthy work of Lieutenant-Colonel Lawrie is in a foot-note on page 218, and the work of the Hyderabad Commission is referred to with almost equally scant reference, as is also the work which has been done in this country on the same subject. The article on Bromide of Ethyl is also imperfect for similar reasons. Although Howard's method of resuscitation is mentioned, various criticisms of it are ignored, and the improvements which have been made in it are not mentioned. The book may, therefore, be considered as being a useful summary of the subject up to about 1891 or 1892, and it is to be regretted that the author did not take the opportunity as the book went through the press of including the work which has more recently been performed.

With the well-known book of Dr. Lawrence Turnbull in this country and that of Dr. Buxton, of England, the profession is now supplied with three modern works upon the administration of those drugs which produce general surgical anæsthesia. All of them are exceedingly valuable, and every physician who uses anæsthetics constantly should be possessed of all three.

**A TREATISE ON DIPHTHERIA.** By H. Bourges, M.D. Translated by E. P. Hurd, M.D. Detroit: George S. Davis, 1894.

This book is one of the series known as the "Physician's Leisure Library" series, published by Mr. Davis, at twenty-five cents a

copy, during several years past, and it does much towards maintaining the high standard attained by previous issues of the series. After a careful perusal of its pages, we find that the author expresses the views which we believe to be the best and most recent upon the etiology and pathology of diphtheria, and carefully places in separate chapters all those conditions which have been confused with diphtheria under the head of "false diphtheria." He emphasizes the fact that the disease is primarily and strictly a local one. The chapter on Treatment is, we think, unnecessarily brief, but nevertheless good, although we do not find a description of those remedies to which we most frequently resort in this country. The hand of the translator is seen through many pages, and he has taken care that the apparatus made by American manufacturers and the work done by American bacteriologists should not be ignored. The book is to be commended to those who wish a good summary of our knowledge of the subject as it exists to-day.

INDEX CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, U. S. A. Vol. xv. Universidad to Vzoroff.

Washington: Government Printing-Office, 1894.

The fifteenth volume of this magnificent register of the medical literature stored in the library at Washington differs naturally in no way whatever from its well-known and most-valued predecessors, and as it extends to the letters named at the head of this review, it will be seen that practically the entire alphabet has now been covered, and that so far, at least, the work may be considered complete. To any one who desires at any time to refer to medical literature, recent or remote, this book is a priceless treasure, and the profession should act as a unit in urging upon Congress the importance of contributing towards equally laudable endeavors in that portion of government work which is so beneficent not only to the profession, but to the entire population of the country.

A SYSTEM OF LEGAL MEDICINE. By Allan McLane Hamilton, M.D., and Lawrence Godkin, Esq., with other collaborators. Vol. I. Illustrated. New York: E. B. Treat & Co., 1894.

We have examined the first volume of this very valuable contribution to medical jurisprudence with much interest. "Taylor's Medical Jurisprudence" has been for so many years, above all others, the authority upon such subjects, at least with the medical profession, that the introduction of a rival in literature is worthy of

note. The names of the contributors are in each case a guarantee of their articles, and the scope of each article is sufficient to discuss creditably the subject considered.

It is impossible in the brief notice which we can give this "System" to name all of the authors or even to give a summary of the table of contents. Some of the most familiar names are those of Dr. Mills, of Philadelphia, Dr. Dana, of New York, Dr. Vaughan, of Michigan, and Dr. Sturgis, of New York. The article upon the "Obligation of the Insured and the Insurer" is by that Nestor of the Philadelphia bar, R. C. McMurtrie.

Some of the illustrations through the volume are, unfortunately, not as good as the text.

This "System" is to be completed in two large royal octavo volumes of seven hundred pages each, and should be possessed by every physician, if for no other reason than that he may be able to defend himself in cases of blackmail or in other attempts to do him injury.

AERO-THERAPEUTICS, OR THE TREATMENT OF LUNG-DISEASES BY CLIMATE. By Charles Theodore Williams, M.D.

London: MacMillan & Co., 1894.

This book comprises the Lumleian Lectures for 1893, with an address upon the high altitudes of Colorado, and should be carefully studied by all those who are interested in the relation of climate to disease. It is particularly useful in that it records the personal experience of Dr. Williams with a large number of patients who have been sent away for climatic treatment, and also because Dr. Williams has personally examined into a number of the climates which he discusses. The book also gives us first-rate scientific information concerning many health resorts which few Americans frequent. Its chapters include, first, "The Factors and Elements of Climate;" second, "Temperature and Moisture;" third, "Barometric Pressure in its Relation to Health and Disease." The type is large and easily read, and the style pleasant, notwithstanding the conciseness of the text.

LES UNIVERSITÉS DES ÉTATS-UNIS ET DU CANADA ET SPÉCIALEMENT LEURS INSTITUTIONS MÉDICALES. Par le Dr. O. Laurent. Twenty-two figures and plans. Paris: G. Carré, 1894.

With more accuracy than is common on the part of French or Belgian writers concerning American medical facts, this author has described medical education and medical charities in the United States as he saw them while on an official visit to this country. He obtained numerous pictures, illustrating the insti-

tutions of which he writes, which are scattered in an interesting way through his volume, and although there are a number of familiar American names misspelled, and dollars and francs are sometimes transposed, the book will give a fair impression of our medical resources to the European who may desire to learn something of them through French text.

### *OPHTHALMIA NEONATORUM.*

To the Editors of the THERAPEUTIC GAZETTE:

DEAR SIRs:—The concluding portion of an address by Dr. G. E. de Schweinitz in the August number of the GAZETTE contains some very good suggestions, which I desire to slightly elaborate. In the first place, many surgeons seem to regard purulent ophthalmia as too small an affair to engage their attention, and so they write a prescription for a lotion and direct the nurse to apply it about so often. Unfortunately, it is often the case that the best nurses are not placed in charge of obstetrical nursing, but are given the more brilliant cases of abdominal surgery. In any case it is not a safe procedure. The surgeon should give these cases his personal attention, and the severity of the disease and the results of failure warrant as much care as any capital operation.

The room should be as carefully prepared as if an abdominal operation were to be made in it. All hangings, rugs, upholstered furniture, and unclean articles of every kind should be removed. No sweeping should be permitted, but instead damp cloths for cleansing. The surgeon and all attendants should have scrupulously clean hands and persons. All cloths used in cleansing the eyes should be of gauze or thin muslin, prepared by boiling, and should be kept in a glass jar in a one-per-cent. solution of carbolic acid. Every four to six hours the eyes should be washed out with a solution similar to this:

R. Acidi carbolicæ,  $\text{m}\cdot\text{v}$ ;  
Acidi boricæ, gr. x;  
Glycerini,  $\text{z}\cdot\text{i}$ ;  
Aque, ad  $\text{z}\cdot\text{iv}$ . M.

A small glass syringe does very well for washing the eyes. The lids can be very gently raised and the solution made to flow under them by very slightly depressing the piston. In handling the eyelids the greatest precaution must be observed. The surgeon's hands should

be softened by thorough washing in hot water, and at last dipped in two-per-cent. carbolic acid solution. After this cleansing, small pieces of single- or, at the most, double-thickness cloths should be taken from the jar and laid over the affected eyes and kept there until the next irrigation. As soon as the inflammation has begun to subside, coagulated egg albumin will be found to be a very useful application. It should be applied once daily and left on for at least one hour. It is prepared by taking the albumin of one egg in a shallow dish, and beating it with a lump of alum until it curds. A teaspoonful of this may be applied to each eye.

Some of the advantages of the treatment outlined above are that it will arrest mucous inflammation in any part of the body, and, further, that it is infinitely less painful than permanganate of potassium or bichloride of mercury, carbolic acid being distinctly anæsthetic.

### *HYDROPHOBIA; STATISTICS DESIRED.*

To the Editors of the THERAPEUTIC GAZETTE:

DEAR SIRs:—Will you permit me, through your columns, to ask that my professional brethren will communicate to me the occurrence of cases of so-called hydrophobia in their practice for the year 1894, from January 1, and so on until the end of this year?

I would like in all cases to learn: 1, the sex and age of patient; 2, (a) the kind of animal that is credited with the inoculation, (b) its state of health, (c) the provocation to bite (if any existed), (d) the reasons why the animal was (if it was) deemed rabid; 3, the seat of the bite (or other mode of inoculation); 4, the fact and method of cauterization (if any); 5, the time between the inoculation and the outbreak; 6, the symptoms of the outbreak,—the occurrence of mania or imitation of dog actions; 7, the remedies used and doses, with their seeming effect; 8, the issue of the case and when death occurred; 9, the investigations made to exclude the presence of disease other than so-called hydrophobia; 10, the findings on autopsy, if one was held.

I shall, of course, acknowledge in future publications aid received in continuing my studies in regard to this subject.

Yours respectfully,

CHARLES W. DULLES.

### THE REMOTE RESULTS OF INTRANASAL OPERATIONS.

READ IN THE SECTION OF LARYNGOLOGY AND OTOTOLOGY  
OF THE PHILADELPHIA COLLEGE OF PHYSICIANS,  
OCTOBER 9, 1894.

BY RALPH W. SEISS, M.D.,  
Professor of Otolary in the Philadelphia Polyclinic.

WHILE reports of the successful results of operative procedures upon the nose fill, and perhaps encumber, medical literature, accounts of less favorable sequences are scarcely

to be found in text-books or journals. Yet it has certainly been the almost daily experience of every busy rhinologist to see cases in which there was at least a grave doubt whether a benefit or the reverse had resulted from any given operation.

For convenience of discussion intranasal operations may be divided into three classes,—those upon the turbinated bodies, those upon the septum, and those upon the pharyngeal tonsil. The most frequently performed operations upon the turbinated bodies are galvano-caustic incision and removal of some part of their substance by the nasal snare; curettage and the use of cutting forceps are usually

employed for very localized lesions only, and will not here be considered.

While the permanently good results of galvano-caustic incision in many cases is an assured fact, the writer certainly sees many patients in which even its very moderate employment has been an often very serious disadvantage to the case. This is especially the fact in examples of sclerotic rhinitis where the nose was burned in an early stage of the disease. The inevitable result is to greatly hasten the formation and contraction of the fibroid tissue elements characteristic of the disease, causing extensive scar changes, epithelial "dermoid" metamorphoses, and profound interference with the physiological functions of the nose. Such patients complain, often bitterly, of nasal dryness, of neuralgic pains about the nose and eyes, and especially of aural and laryngeal sequelæ,—deafness, tinnitus, cough, and irritable throat; all symptoms characteristic of the disease, but undoubtedly greatly hurried and aggravated by the very procedure which was intended to cure. Lachrymal obstruction from cicatricial contraction is also far from rare after the use of the electric loop, and should always be taken into consideration before operating.

The deep, light-colored, grooved, and often stellate scars of such operations are well known to all rhinologists, but their great importance is certainly often overlooked; so marked may be the interference with the functions of the nose, that even chronic bronchitis and nasal asthma are not excessively rare results of "thorough" use of the galvano-cautery. The prognosis of such cases is of necessity a gloomy one; the patient is doomed to breathe dry and unprepared air into the larynx and bronchial tubes, the fibroplastic changes set up tend to constantly spread along the mucous membrane and submucous tissues, and all that can possibly be expected is to arrest the changes by properly directed sedative, tonic, and, if need be, mildly stimulating measures.

Another class of cases in which both snare and cautery operations have often, if not usually, a most unfortunate result, is in examples of vaso-motor rhinitis. It might not be too much to say that all operations upon the turbinated bodies which are intended simply to reduce *vascular swelling* are worthless, if not injurious, in this disease, and that many of the procedures in vogue are most hurtful in their remote results. Excessive nasal irritability, spasmodic asthma, and marked constitutional depression are common sequels of the energetic use of destructive agents in vaso-motor condi-

tions. Such cases are not infrequently quite hopeless, and their treatment depends upon the needs of each particular case.

Operations upon the nasal septum very frequently result unfavorably, the condition of the patient at the end of one or two years after the operation being often worse than before. Septa which have been subjected to sawing or chiselling are especially liable to conditions of chronic irritation and vascular distention, frequently leading to ulcerative changes. Cartilaginous overgrowth (ecchondrosis) is also not infrequent, and the writer has often seen, after his own operations as well as after those done by other surgeons, new masses appear much exceeding in size the hypertrophy that was removed. Owing to its scanty blood-supply, the triangular cartilage is especially intolerant, and incurable ulcers, due to the scar changes incident to the healing of extensive cuts in this region, occur in quite a considerable percentage of cases.

Prognosis and treatment depend upon the conditions found in each patient, but disappointment is not seldom the only result to be obtained by the most careful and prolonged treatment.

The brilliant results secured by many operations by the removal of the pharyngeal tonsil have tempted many surgeons to operate upon nearly every case of "adenoids" which presents itself, and as a consequence examples of unfortunate results are not rare. One of the most common of these is persistent crust accumulation in the pharyngeal vault, due to cicatricial changes following the ablation. Mucus adheres to the scarred and atrophied mucous membrane and cannot be removed by hawking, and as there is often considerable pocketing at the vault of the pharynx, a thick crust gradually accumulates, which is most distressing to the patient. Naso-laryngeal irritability, together with an excessive *vulnerability*, have followed a number of operations upon adenoids under the writer's observations. Hay-fever-like paroxysms, repeated attacks of coryza and laryngitis, and neuralgic pains, especially about the sphenoidal sinus, seem to have been directly caused by the shock of the operations. While the writer has seldom, if ever, seen the brilliant improvement in hearing in cases of catarrhal deafness after operations for adenoids, which are so constantly claimed, few weeks pass that he does not see cases of acute or chronic ear-disease directly traceable to these procedures. The Eustachian salpingitis already present seems often to be lighted up with double intensity after the local shock of

an operation, and only great care can prevent serious middle-ear involvement.

The profound shock to the system at large is far greater after removal of the pharyngeal tonsil than is often taught; chorea in children and neurasthenia in young adults occur as a direct sequence occasionally, and great impoverishment of the general health is not very unusual.

The management of such cases is often one of great difficulty, and as cicatrized areas cannot be replaced, and the most "thorough" of rhinologists can find nothing more to remove, the condition of the patient is often a hopeless one so far as the local conditions are concerned.

It is not intended to discuss in the present brief sketch the various *accidents*, whether avoidable or otherwise, which may occur after nasal operations, as after any others, rendering them useless or harmful. It has been intended only to call attention to certain remote unfavorable results which occur in a considerable number of average cases.

Nasal operations have been so highly lauded, and the immediate results are often so gratifying, that rhinologists seem to have come to believe that the intranasal region is absolutely tolerant, and that all that is necessary to cure rhinitis is to destroy some part of the nasal tissues.

The writer has no wish to disparage the brilliant results due to nasal operative surgery, but he believes that great judgment and caution are necessary, and that no operation, however small, should be performed upon the intranasal tissues without a most careful consideration of its remote as well as the immediate results.

Many cases of nasal disease, even of obstructive type, call not for destructive measures, or perhaps for any local treatment, but are most benefited by tonics, electricity, rest, and proper exercise, all prescribed only after a careful general study of the case.

It should be remembered that the causes of many forms of rhinitis are wholly unknown, and that others are known to depend upon causes in the central nervous system, and to try to benefit such cases by the methods of the cabinet-maker seems scarcely scientific. What is most needed in rhinology is not new forms of operative technique, but studies in etiology and the dependence of nasal disease upon the system at large. Histological studies are also much needed, and have been sadly neglected since the study of the fission fungi has become so fashionable.

## THE TREATMENT OF GONORRHOEA BY IRRIGATION OF THE URETHRA.

By H. M. CHRISTIAN, M.D.,

Chief of Genito-Urinary Dispensary, University of Pennsylvania,  
service of Dr. Edward Martin.

IT is proposed in this article to give the results obtained by the writer in the treatment of gonorrhoea by daily irrigation of the urethra.

A large majority of the cases treated were patients at the Dispensary for Genito-Urinary Diseases, University Hospital; a few are taken from the case-book in private practice.

The remedies used for the purpose of irrigation were bichloride of mercury, nitrate of silver, permanganate of potassium, and trikresol. The irrigator employed was the ordinary glass-jar irrigator used in surgical clinics, and was suspended by a rope, working over a pulley, at a height of six feet above the penis, the patient standing.

The Kiefer nozzle was used in all cases, except in those instances where it was found to be too large to enter the meatus properly; in such cases the soft-rubber catheter was employed. In irrigating the urethra, one quart of the solution—warm, not hot—was used daily for a period of two weeks. In a few cases treatment was continued for three weeks; it was, however, observed that no permanent benefit resulted from this extra week's treatment. In other words, whatever result was obtained from irrigation was always apparent at the end of two weeks, and no distinct advantage was ever gained by prolonging the daily irrigation beyond that point.

Treatment was begun in all the cases in the first week of the disease. Purulent discharge from the urethra, ardor urinæ, and chordee were present in all. Microscopical examination of the discharge was made in every case.

It will be understood in the statistics given below that those cases in which gonococci were found are classified as infectious; where, upon repeated examination, no gonococci were found, the case is classified as non-infectious urethritis.

1. *Bichloride of Mercury*.—Strength of solution, 1 to 15,000, increasing the second week to 1 to 8000. Number of cases treated, 20; infectious, 19; non-infectious, 1; improved by treatment,—i.e., discharge becoming less in quantity and thinner,—8; number unimproved, 11; cured, 1; number in which ardor urinæ and chordee were lessened by treatment, 18; number in which ardor urinæ and chordee were not benefited, 2;

number of cases in which posterior urethritis developed, 2; number of cases in which epididymitis developed, 0; number of cases in which gonococci were found in discharge at end of fourteen days' treatment, 19.

2. *Nitrate of Silver*.—Strength of solution, 1 to 6000, increasing in second week to 1 to 3000. Cases treated, 20; infectious, 18; non-infectious, 2; improved by treatment, 13; unimproved by treatment, 6; cured, 1; number in which ardor urinæ, etc., lessened, 20; number in which ardor urinæ, etc., unaffected, 0; number developing posterior urethritis, 2; number developing epididymitis, 0; number in which gonococci were found at end of fourteen days, 16.

3. *Potassium Permanganate*.—Strength of solution, 1 to 4000, increasing in second week to 1 to 2000. Cases treated, 20; infectious, 16; non-infectious, 4; improved under treatment, 10; unimproved, 3; cured, 7; number in which ardor urinæ, etc., lessened, 19; number in which ardor urinæ, etc., unaffected, 1; number developing posterior urethritis, 2; number developing epididymitis, 1; number in which gonococci were found at the end of fourteen days, 5.

4. *Trikresol* (Schering).—Strength of solution, one-half of one per cent. Cases treated, 10; infectious, 10; non-infectious, 0; improved, 1; unimproved, 9; cured, 0; number in which ardor urinæ, etc., lessened, 1; number in which ardor urinæ, etc., unaffected, 9; number developing posterior urethritis, 0; number developing epididymitis, 0; number in which gonococci were found at end of fourteen days, 10.

From a glance at these statistics it will be seen that, as regards therapeutic value, these four remedies stand in the following order: first, permanganate of potassium; second, nitrate of silver; third, bichloride of mercury; and, fourth, trikresol. By far the most valuable remedy in urethral irrigation is permanganate of potassium. It is simply using in a new way what has long been known to every man about town to be a most potent drug in the treatment of gonorrhœa. It will be noted that gonococci were found in the discharge at the end of two weeks' treatment in only five cases.

Irrigation of the deep urethra with a 1 to 4000 permanganate of potassium solution is the very best method of treating acute posterior urethritis, and will result in a cure in most cases in from about three to five days.

Nitrate of silver follows permanganate of potassium very closely, but does not appear to dry up the discharge as quickly or as well.

In regard to bichloride of mercury, it was evident that those solutions which were strong enough to have any positive antiseptic effect irritated the urethra and increased the ardor urinæ. On the other hand, the weaker solutions appeared to act very little better than so much water on the discharge.

Trikresol is a coal-tar product manufactured by Schering, similar in every way to carbolic acid. Solutions of the strength of one-half of one per cent. were found to be very irritating to the urethra, increasing in a marked degree the ardor urinæ. Solutions of a quarter of one per cent. had little or no effect upon the discharge.

Seventy cases in all were treated by irrigation. Of these, seven were cases of simple urethritis. Thirty-two were improved by treatment,—that is to say, the condition at the end of two weeks was simply a thin muco-purulent discharge at meatus in the morning; no ardor urinæ or chordee or frequent and imperative urination; further irrigation did not improve this condition. These cases were all cured in about two weeks more by use of some astringent injection two or three times daily.

In twenty-nine cases the discharge was not at all affected by irrigation. These patients showed marked improvement in their condition upon beginning the use of a urethral injection containing bismuth and hydrastis, and the use internally of a capsule containing sandal-wood oil and copaiba.

Nine of the cases were cured within the two weeks. Of these, seven were cases of non-specific urethritis. Of the nine cases cured, seven were cured by permanganate of potassium. Gonococci were found in small quantity in the discharge after two weeks' irrigation in fifty cases.

Posterior urethritis only occurred in five, and epididymitis in one instance.

It should be noted that in fifty-eight cases the ardor urinæ and chordee were entirely relieved by irrigation; and of the twelve cases in which these symptoms were not affected, nine were treated by trikresol, a remedy which was shown to be very irritating to the urethra.

The results obtained in the treatment of these cases seem to warrant the following conclusions being drawn:

1. That irrigation is a distinct advance in the treatment of gonorrhœa; in fact, up to a certain point, it must be considered the proper treatment for that disease. It relieves ardor urinæ and chordee more promptly than any other form of treatment. It is attended with a much smaller proportion of complications, such as total urethritis and epididymitis.

2. That permanganate of potassium is the best remedy for the purpose of urethral irrigation.

3. That irrigation of the urethra alone cannot be relied upon to absolutely cure specific urethritis.

For the cure of the thin muco-purulent discharge which appears at the meatus in the morning, some astringent injection used by the patient himself is necessary.

4. That simple non-infectious urethritis can be cured in from ten to twelve days by daily irrigations with permanganate of potassium.

The writer is of the opinion that, where it is possible to carry out the treatment, irrigation of the urethra with solutions of permanganate of potassium *twice* daily would very materially lessen the duration of the disease. This is, of course, impracticable in dispensary practice. I am now employing at the Dispensary of the University Hospital daily irrigation with permanganate solution, combined with the internal use of a capsule containing five minims each of oil of sandal-wood and oil of copaiba. The results obtained in these cases will be published at another time. It might be well to mention here that, for the purpose of irrigating the urethra completely, the Kiefer nozzle is not by any means all that could be desired. The blunt nose of the nozzle will not fit properly every meatus. On the other hand, it is very doubtful whether the urethra is irrigated to any great extent by its use, as it was observed in almost every case that the irrigating fluid would make a short circuit in the urethra from the point of entrance in the nozzle to the point of exit.

The best results were obtained from the use of a soft-rubber catheter several sizes smaller than the calibre of the urethra, allowing the solution to escape easily along the side.

The following table will show at a glance the results obtained by urethral irrigation:

# *PNEUMONIA TREATED BY ICE-COLD APPLICATIONS.*

By W. FRED. JACKSON, M.D., C.M.,  
Physician and Surgeon to the Fairknowe Orphans' Home;  
Member of Staff of Brockville General Hospital,  
Brockville, Ontario, Canada.

BETTER results are always to be desired, until we have reached complete success. If we may believe statistics of results attained by the prevalent modes of the treatment of pneumonia, progress has not been made in the proportion of recoveries for the last forty years. Under the ancient usage of bloodletting, starvation, and the liberal use of calomel, we have recorded a death-rate in pneumonia ranging from ten to fifteen per cent. The figures given by several of the larger hospitals of the world during the last few years, and during which time the former methods just enumerated have fallen into abeyance, show a mortality of not less than twenty-two per cent., ranging at times much above this figure. I think it fair to argue from this that the alterations in the methods of treatment have not been made in the right direction, and that better results are still to be desired. We have gained the *suaviter in modo*, but we have lost the *fortiter in re*. We have made it pleasanter for the patient at the expense of his welfare.

To the October number of this journal for 1892 I contributed an article detailing the results attained in twenty-five consecutive cases of pneumonia treated by the application of ice-cold compresses to the chest-walls. The cases were not detailed at length, but the results given showed that all the cases but one recovered, and that all these recoveries were remarkably prompt and rapid, with the exception of one. This case was complicated with very extensive fibrinous pleurisy, but eventually made a perfect recovery.

The case that died was in the person of a wretched alcoholic woman, who led a miserable life. Albuminuria was a symptom of grave import observed during the illness, and there

Drug employed.	Number of cases.	Infectious.	Non-infectious.	Improved.	Unimproved.	Cured.	Gonococci found at the end of two weeks' treatment.

4. Trikresol .....	10	10	0	1	9	0	10

was also concurrent general peritonitis. Post-mortem examination revealed contracted kidneys and cystic degeneration of both organs, so that a fatal event under any form of treatment was not to be wondered at.

Upward of a dozen of these cases were afterwards written out in detail, and were published subsequently by Dr. Thomas J. Mays, of Philadelphia, in an article embodying a collective investigation of the treatment of pneumonia by the method indicated by the heading of this article.

As I cannot lay my hand upon Dr. Mays's paper at the present moment, I may, I hope, be pardoned for want of exactitude in quoting it. But, if my memory serves me aright, I believe the mortality as given by the series of cases referred to was about four per cent. I think this is the correct figure. At any rate, I have now seventeen additional consecutive cases of pneumonia treated by the method of ice-cold applications to the chest, in which recovery has taken place without exception. All the recoveries were prompt and satisfactory, with the exception of a single instance. This one, like the one of the first series, was a very severe case of double pneumonia, likewise complicated with extensive fibrinous pleurisy, and a good recovery was eventually attained.

In the course of these series I treated two other cases, but by the prejudices of members of the families I was not permitted to carry out the cold applications. They were, therefore, treated by the methods ordinarily in vogue,—viz., stimulating applications to the chest, the administration of drugs to relieve the pain and fever, and the use of stimulants. Both of these cases died.

These two series of cases—numbering forty-two in all—are, I think, a sufficient test to place the results attained beyond peradventure; and I ask every reader to candidly say, in the light of his personal experience, whether these are or are not better results than are ordinarily attained, and also whether the special method of treatment may not fairly be given the credit for the large proportion of recoveries.

It will simplify and shorten this article to state at once that in all cases of the series about to be enumerated, there was exhibited a mixture which was about as follows:

R. Liquor. ammon. acetatis, ℥iv;  
Spir. ætheris nitrosi, ℥i;  
Syr. scill., ℥i;  
Syr. acacia, q. s. ad ℥viii. M.

Of this, from a dessert- to a tablespoonful was given, diluted with water, every hour or

so, as the case seemed to demand. Various drugs were also used with this combination as indications arose. Of these, strychnine, digitalis, nitro-glycerin, caffeine, potassium iodide, etc., were given *pro re nata*.

The ice-water applications were made by means of large towels, or of suitable pieces of cloth, which, having been wrung out of ice-water, were tucked about the chest, covered with a piece of flannel, and kept snug with a roller bandage. These were changed as frequently as they approached the body-heat, until the temperature fell to normal. After this they were renewed during another twenty-four hours only as they became dry, after which their use was discontinued.

The following is a synopsis of the cases:

CASE I.—Female, aged twenty-three years; right lobar of base and concurrent general peritonitis; temperature, 103° F.; pulse, 120; normality on fourth day; sat up on fifth day.

CASE II.—Male, aged thirty-one years; double lobar pneumonia; hepatized up to nipple-line on both sides; typhomania, with picking the bedclothes, and insomnia; has been under treatment six days by hot applications and alcohol; attendant resigned the case as hopeless this day; cold applications and the alkaline mixture above mentioned with digitalis and trinitrin; normality on third day by crisis; recovery.

CASE III.—Male, aged seven years; right lobar of base; great pain and dyspnœa; temperature, 104° F.; pulse, 140; ice compresses abolished pain in two hours; normality in eighteen hours; recovery.

CASE IV.—Female, aged thirty-four years; pneumonia developing in left apex; temperature, 105° F.; pulse, 106; cold aborted this case in thirty hours.

CASE V.—Female, aged eighteen years; pneumonia, entire left lung; temperature, 104° F.; pulse, 120; ice compresses relieved pain in eight hours; normality in thirty hours; recovery.

CASE VI.—Male, aged forty-four years; lobar pneumonia, left upper half of lung; concurrent pleurisy over whole lung; great pain and dyspnœa; temperature, 105° F.; pulse, 120; pain relieved in seven hours; normality regained fourth day; recovery.

CASE VII.—Male, aged six years; right lobar pneumonia of base, *with concurrent endocarditis*; very ill and much depressed; temperature, 104° F.; pulse, 140; ice compresses on lung and over heart; sixth day, temperature 99.4° F.; seventh day, normal.

CASE VIII.—Male, aged nine years; right

lobar pneumonia; temperature,  $104^{\circ}$  F.; normality on third day,—*i.e.*, after forty-eight hours of the cold applications.

CASE IX.—Female, aged forty years; right basic pneumonia; took ill Friday P.M.; saw her Saturday noon; normal, Sunday A.M.; recovery at once.

CASE X.—Female, aged twenty-eight years; right basic pneumonia; temperature,  $104^{\circ}$  F.; pulse, 120; respiration, 36; very severe case; crisis on eighth day, and recovery.

CASE XI.—Male, aged nineteen years; lobar pneumonia, both bases; very much depressed; looked like a typhoid case; crisis on sixth day; recovered.

CASE XII.—Female, aged twenty years; lobar pneumonia, whole of left and base of right lung; concurrent fibrinous pleurisy; an exceedingly severe and anxious case; recovered after a long and painful illness. Expresses herself to the effect that the cold helped her to breathe, and feels that but for its help she must have given up and died. The pleurisy has left adhesions on both sides.

CASE XIII.—Male, aged sixteen years; right basal pneumonia; temperature,  $106^{\circ}$  F.; pulse, 160; respiration, 46; relieved at once by cold; ill five days; recovered.

CASE XIV.—Female, aged forty years; right lobar pneumonia of base; severe case; high temperature and much dyspnoea; no notes, as surroundings were too bad to take them; attended her four days; recovery.

CASE XV.—Male, aged forty-five years; double basic pneumonia, worst on left side; temperature,  $105^{\circ}$  F.; pulse, 130; respiration, 48; an alcoholic case; cold gave relief within fifteen minutes; after eighteen hours' application, crisis, with temperature  $98.4^{\circ}$  F., pulse 80, respiration 24, and so persisted; recovery.

CASE XVI.—Female, aged ten years; lobar pneumonia, right apex; temperature,  $104^{\circ}$  F.; pulse, 116; cold compresses; relief; fourth day, temperature  $99^{\circ}$  F., pulse 80; fifth day, normal, by lysis; recovery.

CASE XVII.—Female, aged twenty-five years; lobar pneumonia, right base; temperature,  $102^{\circ}$  F.; pulse, 110; much pain, dyspnoea, and rusty expectoration; crisis in thirty hours; normality; recovery.

Aside from the routine application of the cold compresses, each case was treated rationally on its own merits. The alkaline mixture indicated above was given to every case, but modified to suit individual requirements. This was not done with any idea of a specific action of either the medicines or the cold applications. The plan of treatment pursued seeks to

promote a derivation of the blood towards the skin and kidneys, thereby to produce free diaphoresis and diuresis. When this occurs during the free application of cold over the affected lung, a crisis generally ensues, and the case comes to a speedy and favorable termination.

The treatment as herein indicated is followed out upon the conception that pneumonia is an essential febrile disease, of which the lung-lesion is but an incident. I have frequently seen the febrile symptoms of pneumonia in full swing many hours before any pulmonary symptoms whatever were to be detected. I presume this is the experience of every medical man who has been observing disease for any considerable length of time, and goes far, I think, to support the contention above advanced as to the essential nature of this disease.

In concluding this article I would utter a word of warning, the result of personal experience extending over a period of twenty years. It is this: opiates, coal-tar derivatives, and medicinal depressants are exceedingly dangerous in the treatment of pneumonia, and I believe that many of the cases of sudden death which occur in this, the prevailing disease of our cold months, are to be attributed directly to the administration of one of the aforementioned medicaments. I believe that the elimination of these classes of drugs from the treatment of pneumonia would greatly lessen the death-rate; and I also believe that the lessening of bodily temperature, quieting of the circulation, the relief of pain, and the general bodily comfort promoted by the application of cold-water compresses, when once observed, will carry conviction to the most incredulous person.

This treatment was very strongly advocated by Niemeyer upward of twenty-five years ago. I remember well that it was discussed by our professors at college when I was a student, but it was decided, without experiment, to be altogether too dangerous an expedient. It was thought the application of cold to an inflammation would only result in disaster.

After having been misled by this theory for, alas! only too many years, I have eventually become emancipated from it; and I am firmly convinced that a happier era will dawn for both physician and patient when the true value of ice-water applications in the treatment of pneumonia becomes generally known, and accepted by the profession as an orthodox procedure.

BROCKVILLE, ONTARIO, September 1, 1894.

## HYDROTHERAPY IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

BY KARL VON RUCK, M.D., ASHEVILLE, N. C.,

Director of the Winyah Sanitarium for Diseases of the Lungs and Throat.

**T**HERE is probably no disease in which more remedies have been recommended and tried than in pulmonary tuberculosis, and among the many other therapeutic agents, according to prevailing theories at particular periods of time, the application of cold water has been in more or less favor for the cure of the disease in question.

The use of cold water in the course of chronic pulmonary tuberculosis has, however, been largely restricted to institutions, owing to the necessity of trained attendants and the supposed requirements of special outfit in its practical application.

In America much less attention has been paid to its employment than in Europe, and beyond the efforts of Dr. Simon Baruch, of New York, to obtain for it proper recognition, American writers on pulmonary tuberculosis have either ignored it or, at most, mentioned it only in a passing way.

It is now my purpose to present to you the outcome of my experience with the remedy, after having made use of it for the last six years in my special institution for consumptives, where it has been employed in various forms in many hundreds of cases.

In doing so I may state at once that by hydropathic means alone we cannot hope to cure pulmonary tuberculosis, and wish to warn against enthusiastic advocates, who, in their zeal, are apt to neglect all other remedies and depend upon water as a sole means of cure.

Nothing is so fatal to any real advance in phthisio-therapy as the constant endeavor to find one single remedy wherewith to cure our patients, and while the search for better ones, or for specifics, may be entirely proper, the clinician who must treat his cases to-day and to-morrow cannot afford to place his faith and stake the life of his patient upon the current "fad;" but he must sift the wheat from the chaff, and construct for himself a rational course of procedure adapted to the present condition of his patients, and in the light of the indications choose wisely from the remedies which experience has shown to be of value.

In so doing I have found that I have had real and substantial aid from the use of water, and that it has fulfilled certain indications,

presently to be considered, better and more satisfactorily than other means within my reach. I also find that any intelligent person can be quickly taught to carry out the treatment, and that no special apparatus or bath establishment is needed; indeed, all its advantages can be derived from applications so simple that they can be had or be improvised in almost any private dwelling. This is the more fortunate, inasmuch as it brings the method within the reach of every general practitioner, and thus also of patients who cannot afford to seek the benefits of special sanatoria.

The first of the indications for which I can recommend to you the use of cold water most heartily is improvement of the nutritive processes.

To this end we can employ the cold rub, the cold full bath, or the shower-bath, or a combination of them. Beginning with a new patient, the cold rub is given in bed, the night-clothing being removed and the patient covered with a woollen blanket, using water at 90° F., with a wash-cloth or bath-glove pressed out, so that it will not drip, and with a few strokes apply the water quickly and in succession to the arms, chest, and abdomen, the lower limbs, and lastly to the back. Each part, after the water is applied, is quickly dried and then vigorously rubbed with a coarse bath-towel until a gentle glow of the skin is produced. The whole procedure requires less than five minutes, unless, on account of slow reaction, prolonged friction is necessary. With each successive part the wash-cloth must again be put into the water and pressed out as before.

Every two or three days the water is used several degrees cooler, until we reach a temperature of 50° F., the rapidity of reduction in temperature depending upon the readiness of reaction of the peripheral circulation.

Every patient, unless suffering at the time from pulmonary hemorrhage, is eligible to the cold rub.

The cold bath is simply a full immersion for a few seconds in a bath-tub, and must be followed by quick and vigorous friction; it acts more powerfully than the cold rub. The temperature of the water is to be graduated the same as for the cold rub; the contraindications are actual or recent hemorrhage or bloody expectoration, great general debility, and the presence of the menstrual flow; it is best suited for the early stage.

The cold shower is given in the empty bath-tub with the same regulation of temperature of

the water; the time should at first be only a moment, and should never exceed more than two or three seconds. A shower can be easily improvised in the patient's room, if necessary; dry friction must follow. It acts still more powerfully than the cold rub or cold bath. It should not be used with patients who are weak or debilitated and have subnormal morning temperature, who react slowly from the rub or bath, nor with such as have at the time acute processes in the lungs; hemorrhage or menstruation also forbids its use.

As stated before, the temperature of the water must be slowly reduced, and in the summer months cooling with ice is, of course, necessary.

All patients learn to like these cold applications; they are simple and easily given, and I do not know that we have anything to substitute for them. In one form or other they become the daily practice with every case and during the entire course of treatment, and must be recommended for regular employment after a cure has been established. Their effect becomes soon manifest in a better cutaneous circulation, the patient feels exhilarated, and his appetite improves.

Whatever may be your estimation of the value of the cold full bath, for fever accompanying other diseases, I desire to warn against its use in septic fever, which is the form we encounter in the advanced cases of pulmonary tuberculosis.

These septic fevers are the results of destructive changes in the lung, under which breaking down, suppuration, and expulsion of dead tissues occur, and any immersion in water cold enough and long enough to materially reduce the temperature in such debilitated subjects is fraught with the greatest dangers from severe pulmonary congestion, hemorrhage, and heart-failure. For the purpose of reducing temperature I have discarded every other form except the use of the ice-bag and the cold pack, but find these of great value, incomparable to the use of any known antipyretic drug preparation. The cold pack consists of the use of three or four thicknesses of linen crash towelling wide enough to reach from under the arms to the middle of the abdomen and long enough to pass around the body and lap over several inches in front. Several such sets must be in readiness, and while one is in use the others are kept drying.

The towelling is wrung out of the water and applied covered with a flannel binder; the temperature of the water is quickly reduced

from 90° to 60° or 50° F.; the latter degrees can, as a rule, be reached in three or four days.

In cases where the temperature rise begins with chill, reaction from the latter must have been established before the cold water is applied, and I have frequently averted the chill by using hot-water packs for an hour before and for an hour after the time at which the chill occurred on the previous day, then reducing the temperature of the water five to ten degrees lower for each change until the desired cold is reached. According to the degree of fever, the temperature of the water used, and the effect obtained, the packs are changed every fifteen to thirty minutes, or less frequently, and this is to be kept up the entire period of the day during which the temperature is above 100° F. When the packs are discontinued for the remainder of the day or night, the chest is washed off with alcohol and rubbed with a little cocoa-nut oil. After a little experience the changing requires but a moment.

Apart from the slight chilly sensation, which passes off quickly, when the wet pack is applied, a few patients complain of constant chilliness; under such circumstances the temperature of the water must be increased and stimulants administered. Exceptionally the treatment must be discontinued entirely on that account.

I find this method most valuable in the management of obstinate fever cases and incomparably better than the use of antipyretic drug remedies.

Under the use of the pack, the pulse improves, most patients derive great comfort, and the temperature is materially and more lastingly influenced for the better. In milder cases of fever, an ice-bag over the region of the heart during the hours of fever produces equally satisfactory results.

There are other conditions and complications in the course of chronic pulmonary tuberculosis for which writers on hydrotherapy recommend the use of water. After much and painstaking observations, I find that the water treatment can be dispensed with in preference to other modes of procedure, but for the purposes indicated hydropathic applications have been a great help in my special work of treating consumptives, and I am confident that if you will give your patients all proper care in other directions, you will find that this addition to your resources will always help and often turn the vacillating scale in the right direction.

*THE USE OF HYPODERMICS OF ALCOHOLIC STIMULANTS FOR THE RESUSCITATION OF STILL-BORN INFANTS.*

BY BEDFORD BROWN, M.D., ALEXANDRIA, VA.

I, in common with others of our profession, have found it not infrequently extremely difficult, and too often, to my disappointment and chagrin, impossible, to resuscitate still-born infants. The loss of an infant at birth in large families may not be a great source of grief, but there are circumstances under which it may become of infinite importance to preserve the life of the child at birth. However, leaving out considerations of this kind, it is always desirable to the attending physician to save the life of every new-born infant intrusted to his care.

During the past three or four years, in several cases of this kind, apparently under the most hopeless circumstances, when all other standard methods had failed, I have resorted to hypodermics of brandy or whiskey, with the most satisfactory results. Such have been the prompt results in these cases that I now, when a case of this kind presents itself, resort to this remedy in the very beginning, as soon as I find that I have a still-born infant to resuscitate, and I am never disappointed in the results. Except in some rare cases where life has ceased some time before birth, I feel satisfied that I could use this remedy, to the exclusion of all others, with positive reliance.

A hypodermic of 5 or 6 drops of the stimulant is administered in first one arm and then the other, and promptly the circulation and entire nervous system respond to its action. In the case of the still-born infant, cold, limp, apparently lifeless, without cardiac action or pulse, and entire absence of respiration, the first act of the infant under the effect of the stimulant is to widely expand the eyelids. Then, in place of the dark lividity of the complexion, a sudden roseate hue extends over the entire surface; then an inhalation, followed by a sudden sharp cry, denoting that the machinery of the circulation and respiration is in operation and life restored.

So far, in all instances in which I have resorted to this remedy in this class of cases, it has never failed to restore the action of the heart, the circulation, the respiration, and heat-germinating processes promptly.

In a recent case of this kind, after a long, tedious labor, in which the infant's head was greatly compressed, and at the time of birth

was apparently hopelessly dead, and in which there was entire absence of all cardiac action or respiration, 5 or 6 drops of brandy injected in each arm produced magical effects, after all the standard methods had been resorted to for resuscitation and had signally failed. In this case a sudden and wide expansion of the eyelids, a gasp, then a deep inspiration, when a universal rose color diffused itself over the surface in place of the dark, livid complexion, then a sharp cry, and cardiac action and respiration were set in motion and life restored.

In the several cases in which I have tried the remedy—all marked cases of asphyxia of the new-born—the effects have been wonderfully quick, prompt, and certain. But there is one class of the still-born in which it can avail nothing. In this class of which I speak, the mother has suffered alarming antepartum hemorrhage and the infant's circulation has been drained of all blood before birth, and the still-born in this case presents the appearance of an infant made of pure white wax, instead of the lividity of asphyxia. In its practice we must draw a line of distinction between these two classes of cases, or we will be disappointed.

In another class of cases—that of the still-born resulting from the action of ergot on the circulation of the child through the mother—it is available. In this particular condition the tonic contraction of the uterus caused by the ergot has effectually served to cut off the supply of oxygen to the foetus, and consequently it becomes asphyxiated and at birth is a still-born child. We know that a large proportion of infants born under such circumstances are never resuscitated.

In a case of this kind, in which the infant was to all appearance dead, after all scientific methods had failed and the case had been surrendered by the physician, hypodermics of whiskey were given in both arms and then in the back, with the most satisfactory results.

After my experience in this case, I feel that I am at liberty to say that the hypodermic treatment of the still-born from the action of ergot will prove effectual, if not in all, certainly in a large majority of these cases.

Now, in regard to the quantity of stimulants that the system of a still-born infant can bear, I will state that 15 drops is the largest quantity ever given in a single case by myself, but I feel sure that an asphyxiated infant can bear with safety twice that amount.

# THE TREATMENT OF EPITHELIOMA OF THE SKIN.

READ BY TITLE AT THE ANNUAL MEETING OF THE STATE  
MEDICAL SOCIETY OF PENNSYLVANIA, MAY 16, 1894.

BY M. B. HARTZELL, M.D.,

Instructor in Dermatology, University of Pennsylvania.

IT is the purpose of this paper to consider briefly the treatment of epithelioma from the dermatologist's point of view rather than from that of the surgeon; consequently, it will deal chiefly with the early stages of the disease and with the smaller and more superficial lesions. I have chosen this somewhat trite but always interesting subject because I believe that, notwithstanding the serious prognosis which attends this malady, in many instances proper treatment, undertaken at the right time, will result in cure; or, when this may not be attained, the patient may be spared much disfigurement and pain and a fatal issue be rendered remote. The neglect of small and superficial epitheliomata, not by the patient, but by his medical adviser, is often responsible for the most serious results and the too frequent failure of treatment, which is only undertaken because it can no longer be deferred. A small nodule, which could readily be removed or destroyed when it first makes its appearance, is allowed to remain, it may be, for years without interference, until it suddenly takes on unexpectedly vigorous growth and rapidly involves structures and important parts, resisting all efforts with the knife or caustic to stay its progress.

Before considering the various methods of treatment it may not be amiss to emphasize anew the paramount importance of early interference. If treatment is begun while the lesion is small, not only will serious disfigurement be less apt to result, but the chances of permanent cure will be enormously increased. It is this fact which leads me to give special prominence to certain methods which, on account of the ease of their application, are more likely to be employed early by the physician and submitted to by the patient than the more strictly surgical procedures.

As to the various remedies to be employed, there is no specific for carcinoma; all internal remedies which have been lauded as curative have failed completely when submitted to the test of experience. There is but one way in which to successfully cope with the disease, and that is to remove or destroy it by local treatment. There are various ways in which this destruction may be accomplished, and

each has its appropriate uses, its advantages and disadvantages. In many instances excision is the speediest and surest way to remove the neoplasm, but there are various reasons why this cannot always be done. In many cases an insuperable obstacle is met in the refusal of the patient to submit to anything like a surgical operation for what he regards a small affair, and this is a serious obstacle and one of the chief reasons why small and as yet comparatively benign growths are not oftener removed early. When excision is selected as the method of treatment, it is to be performed according to the ordinary rules of surgery, and it will not be considered further here, except to call attention to the ease with which small epitheliomata may be painlessly excised with the aid of cocaine anæsthesia.

Another operative procedure more or less frequently employed is erosion or scraping out the diseased tissues with the sharp spoon or curette. The manner of using this instrument is probably familiar to you all, but I wish to say a word as to the real usefulness of this method of treatment, since I have very well defined notions concerning it which are not in exact accord with those generally entertained. The usefulness of the curette, when used alone, is very limited, since it is next to impossible to remove the growth completely with it, and partial removal is time wasted; half-way measures are not to be tolerated in this disease. If, however, after thorough scraping, an active caustic is applied, good results are often obtained.

Another method of dealing with this malady is by cauterization, either with the actual cautery, as by the thermo-cautery or galvano-cautery, and by chemical caustics. Both the Paquelin and the galvano-cautery are efficient and manageable, and they may be advantageously employed when the growth is small or when hemorrhage is to be feared. The actual cautery, however, is in most instances very painful, and is apt to produce cicatrices more disfiguring than those which result from the chemical caustics or excision. Furthermore, it is not always easy to persuade the patient to permit its use, since there is something especially terrifying in the idea of being burned.

But of all the means at our command for the treatment of epithelioma, such as are under consideration, the chemical cauterants are the most generally useful. I am well aware that this statement will not meet with general approval, and that it is not in accordance with

the opinions generally held, especially by surgeons; but a not inconsiderable experience leads me to believe that the complete destruction of the morbid growth can be more readily and, in some instances at least, more thoroughly attained by the proper use of caustics than in any other way. An important advantage possessed by these agents is that their use is rarely objected to by the patient; in consequence, early treatment is much more apt to be submitted to. The list of caustic substances which have been employed is a considerable one, and it is not a matter of indifference which one we employ, since these differ widely as to the amount of pain produced, their penetrative power, and the rapidity with which they destroy.

In our choice of a caustic, we should, first of all, be guided by the thoroughness with which the tissues are killed; the mild ones, which act only superficially, should be rejected, and such substances as lactic acid and the more recently introduced trichloroacetic acid are altogether unsuited for the treatment of these lesions, since they do not penetrate deeply enough. Doubtless the employment of mild cauterants has done much to impair confidence in the utility of this method of treatment and to bring it into disrepute, since these, acting as irritants rather than destructive agents, only tend to stimulate the growth of the neoplasm. It is not my purpose to consider in detail all the various agents which may be employed, but only to call attention to a few reliable ones which, for one reason or another, I believe best suited for the treatment of the affection under consideration.

One of the oldest and most efficient of the chemical caustics is arsenic; it is thorough in its action, and belongs among what may be termed selective caustics, by which is meant that it attacks the morbid much more rapidly than the healthy tissues. It is usually applied in the form of a paste, made by combining arsenous acid with powdered acacia and water in varying proportions. The employment of this agent is attended by two serious disadvantages,—the extreme pain which usually accompanies its action and the danger of toxic effects when applied to a considerable surface. When the growth is small, sufficient destruction may be produced by using a paste of moderate strength (1 to 8), allowing it to act for two to three days; a paste of this strength does not produce such intolerable pain as the stronger ones.

Chloride of zinc, which acts rapidly and which may be made to penetrate to almost any

depth desired, is one of the most reliable and thoroughly efficient agents of its class. It is particularly useful when the neoplasm is of considerable size and has invaded the deeper structures. It has the further advantage of rendering the blood-vessels impervious, so that hemorrhage does not occur, even when tissues containing vessels of considerable size are destroyed. There are many formulæ for its employment, but the paste made up with flour and water, twenty-five to fifty per cent. strength, known as Canquoin's paste, is a convenient and ready method of applying it. It produces a gray leathery eschar, which varies in thickness, according to the strength of the paste used. At the end of fifteen to eighteen hours its action ceases, owing largely to the impenetrability of the slough formed.

Potassium is a powerful and deeply penetrating caustic, destroying much more rapidly than either of the foregoing. Some care is necessary in using it, since, owing to its deliquescence, it is apt to spread much beyond the point to which it is applied. Because of the permeability of the slough produced by it, it penetrates deeply, and in order to prevent unexpectedly deep destruction of the tissues, its action should be neutralized by the application of vinegar or dilute acetic acid when the desired depth has been reached.

One of the very best remedies of this class is, on many accounts, pyrogallol, and it is especially indicated in the small superficial epitheliomata so commonly seen upon the face. Owing to the comparative slowness of its action, it is easy to regulate the amount of tissue destroyed, and, as it is almost or quite painless, few patients object to its employment; it produces far less inflammatory reaction in the surrounding parts than any of the caustics above mentioned. In using chloride of zinc and pyrogallol it should be remembered that the eschar, after it has attained a certain thickness, protects the tissues beneath it, and if it is desired to penetrate to a considerable depth, it is necessary to remove this eschar and reapply the caustic. This may readily be done in thirty-six to forty-eight hours by the application of lint kept wet with a saturated solution of boric acid.

In conclusion, I would urge the more frequent use of caustics in the earliest stages of epithelioma, since I believe that a large proportion of cases which would refuse any operative interference would readily submit to this form of treatment and with entirely satisfactory results.

FIVE CASES OF ACUTE NEPHRITIS IN CHILDREN, WITH SPECIAL REFERENCE TO Pilocarpine in the Treatment.

By G. W. LUECK, M.D., JUNEAU, WIS.

IT may be of interest to precede this report with a brief review of the experience of some authorities with pilocarpine in nephritis.

Lewis Smith, in his "Diseases of Children," sixth edition, says, "Given in moderate doses and with sufficient interval, pilocarpine has never in my practice had any deleterious effect. It is apparently the most useful and important diaphoretic for the disease which we possess."

Hirschfelder, quoted by the same author, after speaking of its beneficial action in relieving various forms of dropsy, adds, "In some morbid conditions of the kidney, however, jaborandi is the remedy *par excellence*, and particularly in the acute parenchymatous nephritis which frequently follows scarlatina. . . . This disease heals spontaneously if the danger that threatens life from reduction of the urine and from the effusion of fluid into the cavities of the body be averted. In this disease jaborandi works wonders."

Tyson, in the *International Clinics* for July, 1891, says, "Jaborandi and pilocarpine are the most useful and important diaphoretics in the Pharmacopœia. That their use is, however, attended with some danger is also conceded, while a depressing effect on the heart is one of the harmful effects; œdema of the lungs is undoubtedly the greatest danger. But that death in uræmic convulsions is also ushered in by œdema of the lungs where pilocarpine has not been administered is also to be remembered, and not every case of death with œdema of the lungs when pilocarpine has been given dare be ascribed to this drug. At the same time, in view of this danger, where perspiration can be promptly induced by the hot-air bath, it should be performed. Should it, however, be impossible to secure sweating in this manner, I do not hesitate to give pilocarpine hypodermically, and repeat in fifteen minutes if the desired effect does not follow. Extreme danger requires corresponding remedies, and some risks must be taken."

Osler gives his experience in the following words: "It is a drug to be used with care. I abandoned its employment for many years after having several cases of severe collapse. Latterly I have resumed its use, often with benefit."

Strümpel says, "Besides hot baths and packs, one diaphoretic remedy is to be especially con-

sidered in renal disease, and that is pilocarpine muriate. In general we prefer the hot bath to pilocarpine, and we try the latter only when the baths are contraindicated or do not exert any satisfactory action."

My personal experience with pilocarpine is limited to the following cases:

CASE I.—E. L., female, aged eleven. My attention was first called to this case November 22, 1891, the father stating that the child had not been feeling well for some time, and that for a few days previous to my visit her face had swollen. On close inquiry, it was found that a brother of the patient had been sick before her with sore throat and a rash, but it was not considered of enough importance to call a physician. He was simply kept out of school about a week. Then this patient complained of sore throat, but had no rash, and was not considered sick enough to remain out of school until œdema of the face showed itself. Considering this a history of mild attacks of scarlet fever, and the urine containing a large amount of albumin, with considerable œdema of the face and ankles, the diagnosis of scarlatinal nephritis was made. Treatment consisted of a calomel purge and pilocarpine muriate,  $\frac{1}{4}$  grain every three or four hours, absolute rest in bed, and strict milk diet. The urine gradually increased in quantity, the œdema diminished, and the patient was convalescent December 2.

CASE II.—E. B., male, aged seven; was called to this case May 9, 1892. The patient was found in a convulsion; no history of scarlet fever or sore throat; considerable œdema of face and ankles; urine highly albuminous. The convulsion passing off very soon after my arrival, a calomel purge was ordered, followed by pilocarpine,  $\frac{1}{4}$  grain every three or four hours. As in the preceding case, it very promptly diminished the œdema and increased the quantity of urine. Patient convalescent May 13.

CASE III.—P. B., male, aged nine; first seen November 18, 1893. This patient was found in a severe unilateral convulsion, this being the first intimation the parents had of his illness. The convulsion was speedily controlled by a hypodermic of morphine,  $\frac{1}{8}$  grain, and rectal injections of chloral and potassium bromide; urine highly albuminous. Calomel and pilocarpine were administered, as in the preceding cases. Patient was convalescent in a week. There was no history of scarlet fever or sore throat in this case, the parents being inclined to assign as a cause of the convulsion a punishment administered by a school-teacher on the previous day.

CASE IV.—H. K., male, aged five. This patient was brought to my office January 28, when the father gave the following history: The little fellow had not been feeling right for some time; had lost his appetite and strength. As is frequently the case, the parents thought the trouble of little consequence, administered household remedies, and allowed the child to accompany his older sister to school up to a few days before he was brought to me. On undressing him one night his father noticed that his ankles were swollen. No more attention was paid to this, however, until the face became oedematous, when I first saw him. Being unable to obtain a specimen of urine just then, the father was made acquainted with the serious condition of the child, and was ordered to have him put to bed immediately on their reaching home, and was asked to bring a specimen of urine as soon as one could be obtained. It was brought the same evening, and found to be loaded with albumin. A calomel purge was administered that night, and after it had operated,  $\frac{1}{10}$  grain of pilocarpine was to be given every three hours until diaphoresis or salivation was induced. The patient was then passing about eight to ten ounces of urine in the twenty-four hours. On the 31st the father informed me that the patient could not tolerate the medicine, as it nauseated him and seemed to quicken his heart, so that the impulse was perceptible on the patient's shirt. There had been very slight diaphoresis, but no salivation. The pilocarpine was then stopped and compound jalap powder given every four hours, in the hope that it would accomplish by watery evacuations what the pilocarpine would have done through the skin and salivary glands had the patient's heart allowed its administration. Milk was the only nourishment allowed, and for the continuous thirst the patient was allowed to drink freely of cream of tartar lemonade. The following evening (February 1) Dr. Sears saw the case in consultation. Not deeming it advisable to administer pilocarpine, on account of the condition of the heart, the temperature of the room was raised to 85° F., and the patient surrounded by hot-water bottles to try to induce an action of the skin, but with little success. The wet pack was also tried, but the patient objected to this and fought so strenuously that it was abandoned. He had a few slight attacks of partial eclampsia, which were promptly controlled by hypodermics of morphine,  $\frac{1}{16}$  grain. A few doses of half a drop of Croton oil were administered in cream, as the compound jalap powder had not acted satisfactorily. There were a few more watery

stools before morning, but the urine seemed to be almost entirely suppressed, except what little he voided when his bowels moved. The following day he received active compound cathartic triturations, with no better result. The treatment of hot-water bottles alternately with the active compound cathartic triturations was continued until the 17th, when death occurred. On the 5th uræmic amaurosis occurred, which lasted to the end.

CASE V.—W. M., aged five; came under observation June 28, 1894; has always been healthy; no previous disease or injury until present disease began.

*June 19.*—Patient first complained of a stiff neck, lost his appetite and strength; this was succeeded by extreme languor, the patient falling asleep in all positions and under all conditions. When first seen on the 28th of June the patient's face was extremely oedematous, skin hot and dry, pulse 90, temperature 99° F., tongue slightly coated, complete anorexia; complained of headache; no other pain or dizziness; bowels constipated; the mother stated that she was not sure as to whether they had moved in a week or not; on being requested to empty his bladder, the patient voided about six drachms of urine, which, on examination, showed albumin.

*Treatment.*—Calomel and sod. bicarb., 1 grain of each, every hour until five have been taken or until bowels have acted; after this pilocarpine muriate,  $\frac{1}{16}$  grain every three hours, until diaphoresis or salivation are induced; mother instructed to save the whole amount of urine for twenty-four hours; patient to be put to bed and kept there on strict milk diet; for the thirst is allowed to drink freely of cream of tartar lemonade; after this the record reads as follows:

*June 29.*—Pulse 90, temperature 99° F.; has had one stool; skin seems to be a little moist; has vomited considerable, perhaps from the effect of the calomel; pilocarpine continued, with the injunction to stop as soon as indicated.

*June 30.*—Pulse 120, temperature 102.5° F.; had one small stool at 4 P.M.; yesterday vomited twice; sweat very freely during night; quantity of urine about six ounces last twenty-four hours; pilocarpine continued; heart tonic and stimulant half a tablespoonful every four hours; hot poultice over region of the kidneys.

*July 1.*—Pulse 90, temperature 99° F.; very bright this morning; voided about ten ounces of urine in the last twenty-four hours; talks intelligently and takes an interest in his surroundings; mother stated that he had sweat

"fearfully" the previous afternoon and night; bowels moved once; treatment continued.

*July 2.*—Pulse 100, temperature 100.5° F.; just as bright; not near so thirsty; urine, about sixteen ounces; skin is moist; pilocarpine and nitro-glycerin compound continued; ordered another poultice.

*July 5.*—Patient continues to improve; cedema very much diminished; pilocarpine to be kept up every four hours; besides this, 5 to 6 minims tinctura ferri chloridi after meals; patient convalescent.

Pilocarpine must be our sheet-anchor in renal dropsy, especially in children. To advise the use of hot baths and packs in these cases is, at least in my experience, one thing, but to administer them is decidedly another. If our patient is a child from three to five years old there will certainly be a fight, and if we persist, more harm than good will be accomplished from the exhaustion following the struggle. In Case I. treatment was begun by infusion of digitalis and potassium acetate, but the patient could only take a few doses on account of the nauseating taste. As the record shows, pilocarpine very promptly accomplished the desired result. In Cases II., III., and V. no temporizing measures were tried, but pilocarpine was administered immediately, with the most satisfactory result.

If, in Case IV., the pilocarpine had been kept up or given hypodermically when the stomach refused to accept it, the patient would probably have had a better chance for his life.

In my experience, the treatment of acute nephritis with urgent symptoms in children resolves itself into,—

1. Absolute rest in bed.
2. The administration of pilocarpine and alkaline drink.
3. Aiding the action of pilocarpine by hot flaxseed and mustard poultices over region of the kidneys, if the patient will permit them, supporting the action of the heart by proper remedies.

After the urgent symptoms have been relieved, the patient must be treated according to indications; if anæmic, tinctura ferri chloridi must be given in full doses, etc.

#### STERESOL IN DIPHTHERIA.

Reviewing the therapeutic uses of steresol, PAUL CHÉRON (*La Tribune Médicale*, July 12, 1894) says that this substance is a solution of gum lac, benzoin, tincture of Tolu, and phenic acid, in alcohol, to which is added a little es-

sence of chamomile and sugar. Steresol is a brownish liquid having an agreeable odor. The drug has been proved to be a powerful bactericide. According to the observations of Berlioz and Aschkinazi, it has rendered a special service in the treatment of diphtheria. The remedy should be applied locally twice or three times a day, using in the intervals washings of carbolyzed water of the strength of one per cent. In L'Hôpital Trousseau, of one hundred and ninety-six cases treated with steresol alone, ninety-nine cases were cured, or about fifty per cent. For cases of simple diphtheria, the percentage of cure was eighty-one; for those cases complicated with croup, nineteen. In the statistics published by Aschkinazi there was a percentage of seventy-two in simple diphtheria and of forty-two in cases complicated with croup. On the whole, it seems that steresol is a useful remedy in the local treatment of the malady under consideration.

#### THE TREATMENT OF HEART-DISEASE.

H. HUCHARD (*La Tribune Médicale*, August 2, 1894) prescribes in the treatment of feeble heart a single dose of 1 milligramme ( $\frac{1}{80}$  grain) of crystallized digitalin for one day only, and is in the habit of administering systematically every fifteen or twenty days for several months, sometimes for a whole year, 30 to 40 drops of a solution of digitalin of the strength of 1 in 1000. This procedure is sometimes modified as follows: Every fifteen days, alternately, a dose of digitalin is given, and during three days four to six cachets of theobromine of .50 gramme ( $7\frac{1}{2}$  grains) each are administered. The author recommends also this formula:

Powder of digitalis,  
Powder of scammony,

Powder of squill, of each, 1 gramme (15 grains).

For twenty pills, four or five of which are administered during three or four days.

Huchard considers digitalis the remedy *par excellence* in feebleness of the heart in cardiac disease. Strophanthus calms the heart without strengthening it, and exercises but little influence on the urine. Sparteine is a tonic to the heart, but has no diuretic action. Caffeine and theobromine excite diuresis and may act favorably in feeble conditions. The author has also administered cactus grandiflorus, coronilla, and other similar remedies, but still holds that digitalis is the most marvellous weapon in the therapeutic arsenal. Without this powerful drug cardiac therapeutics does not exist.

THERAPEUTIC GAZETTE with WESTERN MEDICAL REPORTER.....	2.50
THERAPEUTIC GAZETTE with BULLETIN OF PHAR- MACY.....	2.50
THERAPEUTIC GAZETTE with AMERICAN LANCET	3.25
THERAPEUTIC GAZETTE with AGE and LANCET...	4.00

Foreign subscriptions may be ordered through our agent in Eng-  
land, Mr. H. K. Lewis, Medical Publisher and Bookseller, 136  
Gower Street, London. Price 20s. Remittances may be made  
either by Postal Order or Stamps.

Price to Foreign Subscribers direct (postage included), \$2.50 (20  
shillings). English postage-stamps received on remittances.

Editorial communications should be addressed 222 South Fifteenth  
Street, Philadelphia. Articles intended for the Original Depart-  
ment of the GAZETTE will be accepted only with the understand-  
ing that they are contributed to it exclusively.

Authors will receive reprints in pamphlet form, without charge,  
provided the request for them be written on the articles sent.

Business communications should be addressed to the Publishers.

### ACETANILIDE FOR VOMITING.

**A**MONG the many uses to which acetanilide has been put, other than that of an anal-  
gesic, we desire to call attention to its employ-  
ment in the treatment of obstinate vomiting,  
particularly when that vomiting seems to be  
due chiefly to nervous disturbance or marked  
gastric irritability. In the treatment of the  
vomiting following operations, acetanilide is  
particularly useful, and the administration of  
2 grains every hour until 6 grains are taken  
will often prevent this unpleasant sequel of  
operative interference. We have used acetan-  
ilide for this purpose a number of times with  
very satisfactory results, our attention having  
first been called to it by Dr. Brown, of Sioux  
Falls, S. D., who told us that it was his custom  
in country practice to leave acetanilide with the  
nurse after the operation, with instructions to  
administer the drug should vomiting after re-  
covery from the anæsthetic be an annoying  
symptom.

Whether it is of value in the treatment of the  
vomiting of pregnancy we do not know, but we  
would suggest its further trial. Probably the  
best way to administer it is to place the pow-  
dered drug in a little brandy, and then to add  
to a spoon some ice which has been finely pul-  
verized. In this way we not only get the stim-  
ulating and antiemetic powers of the brandy,  
but we aid in the solution and therefore in the  
rapid absorption of the acetanilide. It is pos-  
sible that the drug exercises its antiemetic  
effects chiefly by its influence upon the stomach  
itself, but we are inclined to think that the  
benefit is derived not only from this, but also  
from its influence on the nervous system after  
it is absorbed.

### THE VALUE OF HYPODERMIC INJECTIONS OF MAGNESIUM SULPHATE AS A PURGATIVE.

**S**OME of the readers of the GAZETTE may  
remember that a paper was read before  
the Section on Therapeutics of the Pan-Ameri-  
can Congress a year ago, in which Drs. Rohe and  
Wade detailed the results of their administration  
of magnesium sulphate as a purgative by means  
of the hypodermic needle, but we have not no-  
ticed since that time any contribution to the  
literature of the subject which would indicate  
that the method was regarded with favor among  
any other members of the profession. In a re-  
cent number of the *Medical News*, Dr. Fincke,  
of Baltimore, who is attached to the Johns Hop-  
kins Hospital, has published a brief article, in  
which he throws considerable doubt upon the  
efficacy of this method of treatment. The re-  
sults which he reached were as follows:

After fifty injections there occurred in seven-  
teen hours nine bowel movements,—one in the  
first hour, one in the second hour, one in the  
third hour, one in the fifth hour, one in the  
sixth hour, three in the seventh hour, and one  
in the ninth hour.

Taking a limit of fourteen hours as before,  
out of eleven cases, we have eight in which the  
results were successful and two which responded  
in twenty hours, the character of the stools  
being appreciably altered. However, consid-  
ering the latter as negative, our ratio is: success,  
72.7 per cent.; failure, 27.3 per cent.

Now, comparing these results with those of  
the hypodermic administration, we have:

*Hypodermically*.—Success, 18 per cent.; fail-  
ure, 82 per cent.

*By the Mouth*.—Success, 72.7 per cent.;  
failure, 27.3 per cent.

Although we do not consider the number of hypodermic injections as conclusive, still, to us, the foregoing results cast considerable doubt upon the purgative property of magnesium sulphate exhibited hypodermically in small doses.

An additional fact to be remembered in regard to this matter is one which, so far as we know, has been ignored in its discussion up to this time. Every one recognizes the danger of injecting drugs directly into a vein when the hypodermic method is employed under ordinary circumstances. This danger is, however, very much greater when magnesium sulphate is employed, for while the chances of puncturing a vein are of course the same as when any other solution is in the syringe, yet introduction of magnesium sulphate into the circulation is always followed by the most serious results, and frequently by death.

#### THE VALUE OF CHLOROFORM IN INTERNAL MEDICINE.

WE are so apt to regard chloroform as a pure anæsthetic when taken by inhalation that many of us are wont to overlook its value as an internal medicament, and, as a result of this oversight, lose a valuable aid to treatment in many affections, some of which are apt to obstinately resist the ordinary remedial measures. One of the most important applications of chloroform is its internal use for the relief of pain either in the chest or abdomen, pain in the latter region yielding naturally more readily to its influence. Particularly is this the case where the pain is of a gripping character, either due to irritability of unstriated muscular tissue in the wall of the intestine or to the presence of irritating foods or large quantities of flatus. Under such circumstances 20 to 40 drops of the spirit of chloroform added to two tablespoonfuls of water and perhaps aided by 10 to 20 drops of the spirit of camphor is one of the very best prescriptions that we can give. Further than this, those of us who believe in the value of antiseptic medication will recognize the fact that chloroform, under the circumstances which we have named, not only relieves the pain, but acts as one of the most powerful antiseptics which can be taken internally with moderate impunity. It is a well-recognized fact in therapeutics that many volatile substances seem to exercise very considerable power in checking all forms of watery diarrhoea, and where pain in the abdomen is associated with liquid movements chloroform possesses a third scope for useful-

ness. Not only is it of value in the forms of pain which are due to direct irritation or inflammation in the abdomen, but it is also useful in those pains which are due to nervous disturbance, such, for example, as in ordinary neuralgia of the stomach or true gastralgia. In obstinate vomiting, 2 to 5 drops of pure chloroform in a little water, taken in teaspoonful doses, will often act advantageously, and when the vomiting is due to the ingestion of bad food, particularly food which has undergone some decomposition process, it is especially indicated. In the vomiting of pregnancy, with some practitioners, it is held to be the best remedy. Another very valuable application of chloroform is its employment externally in liniments in cases of muscular rheumatism for stiffness of the muscles due to strain or excessive exercise. Possessing, as it does, not only counter-irritant, but anæsthetic effects, its employment in this manner is most advantageous. Another use to which it is too rarely put is for the production of counter-irritation varying from slight reddening to actual blistering of the skin. Slight reddening is rapidly produced by applying a cloth saturated with chloroform to some portion of the skin so remote from the respiratory apparatus as to avoid inhalation in any large quantity, and the blisters may be formed by placing chloroform on the skin under a watch-glass, so that too rapid evaporation will not take place. For those who are unable to take opium in any combination for the relief of pain in any part of the body, a prescription composed of 30 drops of spirit of chloroform and 10 minims of the fluid extract of a good cannabis indica is a valuable prescription.

#### RHYTHMICAL TRACTION OF THE TONGUE IN THE TREATMENT OF ASPHYXIA.

LABORDE, more than two years ago, communicated to the Académie de Médecin the results obtained by rhythmical traction of the tongue in the treatment of those asphyxiated by submersion. A year later, in an elaborate paper explaining his method and its *modus operandi*, he urged that this method of respiration was the most efficient yet discovered, that it always succeeded in restoring life when Sylvester's method would have succeeded, and that it had repeatedly been efficacious when Sylvester's method had failed; therefore that it should always be the method of choice. He recommended it in the treatment of the as-

phyxia of the new-born, toxic asphyxia, spasmodic and tetanic asphyxia, asphyxia by strangulation, asphyxia following powerful electric shocks, that due to compression or concussion of the brain, and, in fact, to all cases in which death was threatened from failure of the respiratory function. Since this time there have been contributed by many observers hundreds of cases attesting the value of Laborde's method. In many of these direct insufflation, Sylvester's method, and all the other known methods of resuscitation were tried in vain. To those especially interested in the details of these cases, *La Tribune Médicale*, for two years past, will afford instructive reading. Not the least striking of the many reported cases is that of Coutelet, found in *L'Abeille Médicale*.

This physician, wishing to demonstrate to his class Laborde's exact method, took for his subject a girl just dead apparently of tubercular meningitis. The exact time after death is not definitely stated, Coutelet believing that it was not more than three or four minutes. Cadaveric lividity was marked, pupils dilated, the heart had ceased beating, the extremities were turning cold. The tongue was grasped, and was drawn upon at the rate of forty or fifty tractions per minute. In three minutes lividity had disappeared, in another minute inspiratory movements of the wings of the nose were noticed, shortly the heart began to beat, the radial pulse became perceptible, and in about six minutes respiratory movements were re-established. Five minutes later, although tractions were continued, the patient really died.

In *La Tribune Médicale* for July 5 of this year there is reported the case of a young woman, a would-be suicide, rescued after five minutes of submersion, and restored after six minutes of rhythmical traction.

The same journal of another date, under the heading "Physiological Treatment of Apparent Death," narrates the case of a child three and a half years old, suffering from laryngeal diphtheria. Symptoms became so urgent that tracheotomy was performed. Though this required but thirty seconds, the child was apparently dead. Its face was pale, the lips blue, there was no respiratory movement. The tongue was seized in a pair of forceps and rhythmical traction was applied without result for six minutes; then the child began to breathe again, and in a quarter of an hour was for a time out of danger and ultimately recovered.

Laborde has been so insistent in advocating his method, claiming it as the most efficacious and most powerful and most simple of all those

employed against death from respiratory failure, and, moreover, has backed up his arguments with so many striking cases, that his method, by order of the prefecture of police, is now printed and posted in the public places and ambulance posts of Paris, and is taught to those who have to do with first aids in emergency surgery.

Traction upon the tongue, Laborde holds, directly excites the diaphragm to its respiratory function, the sensory impulse being conveyed by the superior laryngeal, the terminal tracheal, and bronchial expansions of the pneumogastric, the glosso-pharyngeal, and lingual, thus exciting a reflex which is expended upon the motor respiratory nerves, particularly the phrenic.

Laborde's method is applied as follows:

The asphyxiated person is placed on his back, with the head low, the clothing is loosened about the neck, and the jaws are opened and kept open by a wedge passed between the molar teeth, a knife-handle, a cane end, any object of suitable size, serving for this purpose. The throat is freed of mucus by the finger or a handkerchief wrapped about the finger. The thumb and index finger are covered by one thickness of a handkerchief to prevent slipping, and then the tongue is seized as far back from the tip as possible. Fifteen times to the minute and at about equal intervals the tongue is pulled out sharply and the tension immediately relaxed. This traction must be so exerted that the whole body of the tongue is affected and not merely its point. At the time the first two or three tractions are made it is well to introduce the index finger of the other hand into the pharynx, as though an effort were made to induce vomiting.

These tractions should be kept up at least thirty minutes and may be continued an hour. When assistants are at hand this method should be re-enforced by mechanical artificial respiration, which, according to Mareschal, is best applied as follows: Two assistants place themselves on opposite sides of the patient's body and simultaneously make pressure, the first upon the sides of the chest concentrically, the second upon the epigastric region from below upward. This pressure is repeated fifteen times to the minute, being relaxed suddenly. The surgeon who is practising tractions on the tongue thus times his motions with those of the assistants who are pressing on the chest and abdomen. At the moment he exerts traction he counts *one*, when traction is relaxed he counts *two*. Pressure upon the chest and abdomen should be made at the moment the sur-

geon counts two, and should abruptly cease the moment he counts one. Furthermore, this method should be re-enforced by external heat and friction of the body.

Laborde's method commends itself because of its instant applicability, especially in cases of threatened asphyxia during ether or chloroform narcosis, and because, if reported cases are worth anything, they show that it succeeds where Sylvester's method has failed.

Every anæsthetizer has, or should have, a pair of flat-billed forceps with which to seize the tongue and draw it forward when respiration becomes obstructed or fails. This procedure is usually sufficient to re-establish normal breathing, not because, as is commonly believed, the epiglottis is drawn upward, thus freeing the larynx,—for Hare and Martin have shown that traction upon the tip of the tongue has no effect upon the position of the larynx,—but because a reflex is thus excited.

Outside of France, Laborde's method has been but little tried. It has apparently given such universal satisfaction to Frenchmen that it would seem well worth while for surgeons of other lands to either corroborate or disprove Laborde's claims.

## Reports on Therapeutic Progress.

### CREOSOTE IN TUBERCULOSIS.

PAUL CHÉRON (*La Tribune Médicale*, August 23, 1894) refers to J. Simon, who advises the association of creosote, iodoform, and salol in the treatment of tuberculosis, in the form of rectal injections. This formula is proposed for every 10 kilogrammes (22½ pounds) of the body-weight:

Pure beech-creosote, .40 gramme (7 minims);  
Iodoform, .005 gramme ( $\frac{1}{4}$  grain);  
Salol, .40 gramme (6 grains).

The above is to be dissolved in a sufficient quantity of pure olive oil to make 10 cubic centimetres (2.7 fluidrachms), and used for a daily rectal injection. The injections are said to be well borne. Out of thirteen cases of tuberculosis treated with this method by Simon, there were five notable ameliorations (the cases being in the second stage of the disorder), three remained stationary, three were made worse, and two of the patients died. It is stated, on the whole, that the results are negative in febrile cases and bad in those cases in which the disease runs a rapid course. The

medicament appears to be indicated only in afebrile cases.

### CHLORALOSE NOT EFFICIENT IN THE TREATMENT OF THE INSANE.

The failure of chloralose to do good in the treatment of the insane is recorded by E. MARANDON DE MONTYEL (*La France Médicale*, August 24, 1894). Nine cases of mental disease, characterized by visionary hallucinations, are described in detail, in which chloralose was tried as a therapeutic agent. The results were distinctly bad in eight of the cases, all of these being made worse. The author proposes to give the drug further trial, notwithstanding the fact that the effects of chloralose in the treatment of mental disease has been so far, according to his experience, decidedly discouraging.

### CORROSIVE SUBLIMATE IN THE TREATMENT OF DIPHTHERITIC ANGINA.

MOIZARD (*La Nouveaux Remèdes*, August 24, 1894) gives an account of his experience in the treatment of diphtheria by the local applications of corrosive sublimate in glycerin solutions of the strength varying from 1 in 20 to 1 in 30 or 1 in 40. The first solution is preferred for children over two years old, and the other two solutions for those below this age. The applications are made twice or three times a day by means of a brush, care being taken to prevent the remedy from being swallowed. The results are said to be most satisfactory. The treatment is continued for several days after the disappearance of the false membranes. In one hundred and twelve cases treated the author obtained a complete cure in eighty per cent., and refers to other practitioners giving a higher percentage with the same method. He asserts that the solutions indicated produce no caustic effects.

### THE TREATMENT OF SCARLATINA.

An interesting article is published by J. COMBY (*La Médecine Moderne*, August 22 and 25, 1894), from which we cull the following points. The author believes that of antipyretics the least noxious is quinine in the form of a suppository, to be used nightly. For a child five years of age this suppository should consist of the following:

Cacao butter, 2 grammes (30 grains);  
Quinine salt, .25 gramme (3¾ grains).

After quinine, antipyrin may be tried, in the form of cachets, solutions, or suppositories. The salicylates must be used with extreme caution, on account of the condition of the kidneys. When not especially contraindicated, this prescription may be employed :

Salicylic acid, 1 gramme (15 grains);  
Syrup of orange-peel, 50 grammes (1½ ounces);  
Warm distilled water, 200 grammes (6 ounces).

A dessertspoonful every hour, according to the age of the child.

Digitalis is of service not only as a heart tonic and diuretic, but also as an antithermic remedy, since it seems to act on the regulating heat-centres; it must be given in moderate doses. Water is one of the best antipyretics; it should be used in the form of baths, lotions, or by affusion. Cold baths, however, are contraindicated when there is a tendency to asphyxia or collapse. In these cases digitalis, caffeine, the diffusible stimulants, inhalations of oxygen, etc., are to be preferred. The following prescriptions are of service :

1. Tincture of digitalis, 15 drops;  
Syrup of squill, 15 grammes (½ ounce);  
Simple syrup, 45 grammes (1½ ounces);  
Lettuce water, 90 grammes (3 ounces).  
A tablespoonful every two hours.

2. Carbonate of ammonia, 1 gramme (15 grains);  
Peppermint water, 5 grammes (1½ fluidrachms);  
Lime water, 20 grammes (¾ ounce);  
Syrup, 15 grammes (½ ounce).  
From 4 to 6 dessertspoonfuls.

If there be excitement, a tendency to delirium, or ataxic symptoms, bromide of potassium, chloral, musk, and chloroform are indicated. This formula may be employed with advantage :

Hydrate of chloral, .50 gramme (7½ grains);  
Bromide of potassium, .50 gramme (7½ grains);  
Tincture of musk, 10 drops;  
Peppermint syrup,  
Distilled water, of each, 30 grammes (1 ounce).  
A tablespoonful every hour.

When the eruption is tardy, the following mixture appears to give satisfactory results :

Elder-flower water, 120 grammes (4 ounces);  
Spirit of Mindererus, 3 grammes (46 minims);  
Wine of antimony, 2 grammes (½ fluidrachm);  
Syrup of raspberry, 15 grammes (½ ounce).  
A tablespoonful every two hours.

The treatment of complications claims attention. Nephritis is the most frequent of such complications, giving rise to albuminuria, ana-

sarca, and convulsive phenomena. A milk diet is to be preferred when albuminuria is present, diaphoresis enhanced by warm water or hot vapor-baths, and the hypodermic use of pilocarpine. Half a syringeful or a syringeful (Pravaz) of a one- to two-per-cent. solution of the nitrate of pilocarpine is sufficient for an injection; this drug can also be given by the mouth. Diuretics, like acetate of potassium, and purgatives, like jalap and scammony, are likewise indicated in the treatment of albuminuria. For the nephritis proper, astringents, like tannic acid, are recommended. In anasarca, diuretin seems to have acted well, and may be given according to the following combination :

Diuretin, 1.50 grammes (22½ grains);  
Sugar, 2.50 grammes (37½ grains);  
Cognac, 10 drops;  
Distilled water, 100 grammes (3¼ ounces).  
A dessertspoonful every hour.

In such complications as gangrenous, diphtheritic, or phlegmonous angina, local applications of antiseptic remedies to the throat are indicated. Irrigations with solutions of salicylated water one per cent., carbolyzed water one per cent., or borated water three per cent. may also be used with advantage. In very young or unmanageable children, atomization with the following combination is advised :

Tincture of eucalyptus, 2 grammes (½ fluidrachm);  
Boric acid, 20 grammes (308 grains);  
Phenic acid, 4 grammes (61.6 grains);  
Salicylic acid, 1 gramme (15.4 grains);  
Glycerin, 30 grammes (1 ounce);  
Alcohol at 90° F., 50 grammes (1¾ ounces);  
Water, q. s. for 1 litre (1.76 pints).

For prurigo and urticaria, which may appear before, during the course, or at the end of the eruption, ointments of lanolin, vaseline, and tartaric acid are of service. The author does not believe that rheumatism, pleurisy, endocarditis, and pericarditis, occurring during an attack of scarlatina, require special treatment.

#### SUCCESSFUL TREATMENT OF CHOLERA INFANTUM BY A DIET OF WATER AND STERILIZED MILK.

JULES PARA (*Rev. Mens. des Malad. de l'Enfance*, September, 1894) records the details of five cases of choleriform enteritis in children, treated successfully by a diet of water and sterilized milk, as recommended by Luton and Remy. The author has made use of slightly mineral and gaseous waters, such as Soultzmatt

or Vals. The ingestion of water to the exclusion of all else soon caused the disappearance of the diarrhoea and of the vomiting, after which sterilized milk was ordered to be given. He believes that many cases of cholera infantum occurring in bottle-fed children are due to decomposed milk. He has abandoned the administration of bismuth preparations and lactic acid in the newly-born, since these medications seem to do good only in children over two years of age.

#### THE TREATMENT OF EPISTAXIS.

In an interesting article on the etiology and treatment of epistaxis, RIPAULT (*Gazet. Médicale de Paris*, June 9, 1894) formulates the following: Epistaxis is of common occurrence; it often is of an unquestionable clinical importance; its cause varies; it may be due to affections of the nasal fauces, the naso-pharynx, to some acute or chronic general disease, or to visceral disorders. The chief important point to consider is that regarding the nasal cavity, of which a thorough, careful physical examination should always be made by means of a speculum and mirror. It is only in this way that a correct diagnosis can be made, and thus proper treatment applied. Antiseptic plugging is generally sufficient, but this cannot be retained if the hemorrhage continue, or if, after stoppage, it should return. The best safeguard against this accident is galvanism. In regard to other therapeutic measures, these are varied according to the individual cases, but the treatment should always be rational.

#### TURPENTINE VAPORS AND THE ELIMINATION OF URIC ACID.

BENOIT DU MARTOURET (*Lyon Médical*, June 17, 1894) gives the details of two cases,—one of arthritism accompanied with right crural neuritis and cardiac arterio-sclerosis, and the other of pyelo-nephritis of calculous origin, in both of which dry turpentine vapor-baths produced satisfactory results, by distinctly increasing the elimination of uric acid. For these baths the fresh resin of the *pin mugho* was used. In view of the results obtained, the author suggests that cases of pyelo-nephritis, due to the presence of calculi, might be cured by the treatment alluded to. This will in time so reduce the size of the calculus that it may with ease be voided through the natural passages.

#### LOCAL THERAPEUTICS IN DISEASES OF THE SKIN.

CATHELINEAU (*Gaz. Médicale de Paris*, July 21 and 28, 1894) writes an interesting article on the local therapeutics employed at L'Hôpital Saint-Louis, of Paris, in the treatment of skin-diseases. We copy many of the combinations given for the benefit not only of our medical, but also of our pharmaceutical readers.

*Salves.*—Some of these are made in the following proportions: oxide of zinc, ten per cent.; turpeth-mineral, five per cent.; calomel, two per cent.; sulphur, five per cent.; boric acid, five per cent.; iodide of potassium, ten per cent.; iodine, two per cent.; tar, ten per cent. Helmerich's salve is composed of these ingredients:

Sulphur, 10 grammes (154 grains);  
Potassium carbonate, 5 grammes (77 grains);  
Water, 5 grammes (80 minims);  
Oil of sweet almonds, 5 grammes (80 minims);  
Petrolatum, 35 grammes (539 grains).

In all the above mixtures the vehicle is either lard, vaseline, or lanolin, or a combination of lard and lanolin, or of vaseline and lanolin, with the addition of white wax.

*Ointment.*—The following ointment is much used:

Liquid styrax, 200 grammes (1540 grains);  
Calophony (black resin), 180 grammes (2772 grains);  
Elemi resin, 100 grammes (1540 grains);  
Yellow wax, 100 grammes (1540 grains);  
Olive oil, 150 grammes (2310 grains).

*Pastes.*—The combinations that follow are used for the preparation of pastes.

##### (a) Salicylated pastes:

1. Oxide of zinc, 50 grammes (770 grains);  
Salicylic acid, 2 grammes (30.8 grains);  
Rice starch, 15 grammes (231 grains);  
Glycerin, 15 grammes (231 grains);  
Distilled water, 75 grammes (1155 grains).  
Mix and boil down to 140 grammes (2156 grains).

2. Salicylic acid, 2 grammes (30.8 grains);  
Oxide of zinc, 25 grammes (385 grains);  
Powdered starch, 25 grammes (385 grains);  
Vaseline, 50 grammes (770 grains).

In this latter mixture the vaseline may be substituted by 5 grammes (77 grains) of vaseline and 35 grammes (539 grains) of lanolin, or by equal parts of vaseline and lanolin.

##### (b) Dextrin paste:

Oxide of zinc, 40 grammes (616 grains);  
Dextrin, 20 grammes (308 grains);  
Distilled water, 20 grammes (308 grains);  
Glycerin, 40 grammes (616 grains);  
Sulphur or sulphoichthyolate of sodium, 2 grammes (30.8 grains).  
Mix and boil to proper consistency.

**(c) Gum paste :**

Oxide of zinc, 40 grammes (616 grains);  
 Red precipitate, 2 grammes (30.8 grains);  
 Mucilage of gum arabic, 20 grammes (308 grains);  
 Glycerin, 20 grammes (308 grains).

**(d) Lead pastes :**

1. Finely powdered litharge, 50 grammes (770 grains);  
 Vinegar, 80 grammes (1232 grains).  
 Mix and boil to the consistency of paste, and then add 10 grammes (160 minims) of linseed or glycerin.

2. Litharge, 30 grammes (462 grains);  
 Vinegar, 50 grammes (770 grains).  
 Mix and reduce by boiling, and then add 15 grammes (231 grains) each of dextrin, water, and glycerin; again boil to the consistency of paste.

**Soaps.**—The *fundamental* soft soap, so termed, is composed of the following ingredients :

Beef suet, first quality, 59.03 grammes (909 grains);  
 Olive oil, 7.04 grammes (108 grains);  
 Soda lye at 38° Baumé, 22.02 grammes (339 grains);  
 Potassa lye at 38° Baumé, 11.01 grammes (169.5 grains).

To this soap are incorporated several substances, as follows :

**(a) Resorcin-salicylated soap :**

Soap, 84 grammes (1303 grains);  
 Salicylic acid, 3 grammes (46.2 grains);  
 Resorcin, 3 grammes (46.2 grains);  
 Precipitated sulphur, 10 grammes (154 grains).

**(b) Sulphur salicylo-resorcinated soap :**

Soap, 79 grammes (1214 grains);  
 Salicylic acid, 3 grammes (46.2 grains);  
 Resorcin, 3 grammes (46.2 grains);  
 Precipitated sulphur, 10 grammes (154 grains);  
 Tar, 5 grammes (77 grains).

**(c) Iodated soap :**

Soap, 95.05 grammes (1463.7 grains);  
 Iodine, 3 grammes (46.2 grains);  
 Iodide of potassium, 1.05 grammes (16.1 grains).

**(d) Salicylo-creosotated soap :**

Soap, 93 grammes (1432.2 grains);  
 Salicylic acid, 5 grammes (77 grains);  
 Creosote, 2 grammes (30.8 grains).

**Plasters.**—Two fundamental plasters are used for the incorporation of various substances, and they are made as follows :

**(a) Simple plaster :**

Powdered litharge, 1000 grammes (15,400 grains);  
 Lard, 1000 grammes (15,400 grains);  
 Olive oil, 1000 grammes (15,400 grains);  
 Water, 2000 grammes (30,800 grains).

**(b) Diachylon plaster contains in addition :**

White wax, 120 grammes (1858 grains);  
 White pitch, 120 grammes (1858 grains);  
 Larch-tree turpentine, 120 grammes (1858 grains);  
 Gum ammoniac, 100 grammes (1540 grains);  
 Galbanum, 100 grammes (1540 grains);  
 Essence of turpentine, 60 grammes (924 grains).

The simple plaster is non-irritant, but little adhesive. On the other hand, the diachylon plaster is very adhesive, but exerts a decided irritant action, which should be borne in mind when treating acute or subacute inflammations, especially in susceptible subjects. Again, not all substances can be incorporated into these plasters, and it must not be forgotten that pyrogalllic acid, sulphur, anthrarobin, and chrysophanic acid decompose lead salts. The following medicated plasters have been found of service :

**(a) Red plaster :**

Simple plaster, 520 grammes (8008 grains);  
 Minium, 50 grammes (770 grains);  
 Cinnabar, 50 grammes (770 grains).

**(b) Calomel plaster :**

Simple plaster, 300 grammes (4620 grains);  
 Calomel, 100 grammes (1540 grains);  
 Castor oil, 30 grammes (462 grains).

**(c) Oil of chaulmoogra plaster :**

Simple plaster, 400 grammes (6160 grains);  
 Oil of chaulmoogra, 300 grammes (4620 grains);  
 Yellow wax, 100 grammes (1540 grains).

**(d) Cod-liver oil plaster :**

Simple plaster, 300 grammes (4620 grains);  
 Cod-liver oil, 175 grammes (2695 grains);  
 Yellow wax, 125 grammes (1925 grains).

**Glues.**—The base glue is prepared by dissolving commercial gelatin in twice its weight of water, by means of a water-bath. Two medicated glues are used,—the soft and the hard.

**(a) Soft glue :**

Gelatin, 15 grammes (231 grains);  
 Glycerin, 25 grammes (385 grains);  
 Water, 15 grammes (231 grains);  
 Oxide of zinc, 15 grammes (231 grains).

**(b) Hard glue :**

Gelatin, 30 grammes (462 grains);  
 Glycerin, 30 grammes (462 grains);  
 Water, 30 grammes (462 grains);  
 Oxide of zinc, 10 grammes (154 grains).

The soft glue forms a good base for insoluble substances, such as white lead, iodide of lead, white precipitate, etc., in the proportion of from five to thirty per cent. The hard glue is preferred for chloral, camphor, creosote, and ichthyol; but it is impracticable for tannin,

pyrogallie acid, and the salts of mercury, since these substances form with gelatin an insoluble compound. The employment of glues is contraindicated in warm weather or whenever sweating is excessive.

*Epidermine*.—15 grammes (231 grains) each of white wax and powdered gum arabic are well triturated into a homogeneous mass. To this is added a boiling mixture of 15 grammes (231 grains) each of water and glycerin, and agitated until cooled. To this substance the name of *epidermine* has been given. For mixing medicinal agents with epidermine, glycerin should be exclusively used. The following substances make good combinations with epidermine: oxide of zinc, from five to thirty per cent.; turmenol, ten per cent.; chrysarobin, ten per cent.; pyrogallie acid, five to ten per cent.; beech-tar, ten per cent.; resorcin, two per cent.; iodoform, ten to twenty per cent.; corrosive sublimate, one per cent.; ichthyol, ten per cent.; and iodide of lead, ten to thirty per cent.

*Steresol*.—This is considered the best of medical varnishes proposed. It is made according to this combination:

Gum lac, purified, 270 grammes (4158 grains);  
Benzoin, 10 grammes (154 grains);  
Balsam of Tolu, 10 grammes (154 grains);  
Crystallized phenic acid, 180 grammes (2772 grains);  
Essence of cinnamon, 6 grammes (92.4 grains);  
Saccharin, 6 grammes (92.4 grains);  
Pure alcohol, sufficient to make 1 litre (1.76 pints).

*Lotions*.—The following lotions are recommended:

(a) Sulphur lotion:

Sulphur, 50 grammes (770 grains);  
Camphorated alcohol, 120 grammes (1848 grains);  
Water, 880 grammes (13,552 grains).

(b) Stimulating lotions:

1. Camphorated alcohol, 100 grammes (1540 grains);  
Essence of turpentine, 15 grammes (231 grains);  
Ammonia, 5 grammes (77 grains).
2. Camphorated alcohol, 100 grammes (1540 grains);  
Essence of turpentine, 25 grammes (385 grains);  
Ammonia, 15 grammes (231 grains).

(c) Parasitic lotion:

Camphorated alcohol, 4200 grammes (84,680 grains);  
Glycerin, 1000 grammes (15,400 grains);  
Essence of turpentine, 800 grammes (12,320 grains);  
Corrosive sublimate, 6 grammes (92.4 grains).

*Emulsions*.—The most common in use appear to be those of coal-tar, oil of cade, and tar. The following are the combinations:

1. Tincture of Panama wood, 400 grammes (6160 grains);  
Coal-tar, 100 grammes (1540 grains);  
Water, 400 grammes (6160 grains).
2. Oil of cade, 20 grammes (308 grains);  
Alcohol at 90° F., 100 grammes (1540 grains);  
Tincture of Panama wood, 100 grammes (1540 grains);  
Warm water, 780 grammes (12,012 grains).
3. Tar, 20 grammes (308 grains);  
Alcohol at 90° F., 100 grammes (1540 grains);  
Tincture of Panama wood, 100 grammes (1540 grains);  
Warm water, 780 grammes (12,012 grains).

THE PHYSIOLOGICAL ACTION AND THERAPEUTIC USES OF CUPREINE, QUINETHYLINE, AND QUINO-PROPYLINE.

E. GRIMAUX (*La Nouveaux Remèdes*, July 8, 1894) publishes the results obtained in an experimental study of the above substances, homologues of quinine.

CUPREINE.

*Physiological Action*.—Subcutaneously administered, this drug produced in dogs, rabbits, and guinea-pigs a local anæsthesia at the point of injection, this effect lasting for several days, but no tremors or any other convulsive phenomena were observed. For guinea-pigs, the fatal dose varied from 250 to 300 grammes (3850 to 4620 grains), or double that of quinine.

*Therapeutic Uses*.—The chlorhydrate of cupreine was used in simple malarial fever, in doses of from .50 to 1 gramme (7½ to 15 grains); but its antiperiodic action was weak, as were also its hypothermic effects. It caused no vertigo nor buzzing in the ears.

QUINETHYLINE.

*Physiological Action*.—The phenomena produced by this medicament are the same as those caused by quinine, but more marked: analgesia, especially of the leg experimented upon, stupor, bilateral tremors, depression of the temperature from 1.8° to 3.6° F. A dose of .15 gramme (2.3 grains) caused death in a guinea-pig weighing 400 grammes (6160 grains).

*Therapeutic Uses*.—In the form of the basic sulphate this drug was found to be an excellent antiperiodic, in doses of from .50 to .75 gramme (7½ to 11¼ grains). It gave satisfactory results in cases in which quinine had failed. In doses of .75 gramme (11¼ grains) quinethyline cured in three days a case of fever that was not even relieved by four .80-gramme (12.3 grains) doses of quinine sulphate. In another febrile

case, complicated with meningitis, in which quinine had been of no avail, quinethyline effected a cure after four doses of .50 gramme ( $7\frac{1}{2}$  grains) each. This drug was also found superior to quinine as an antiperiodic.

#### QUINOPROPYLINE.

*Physiological Action.*—The action of this remedy was quite decided. In doses of .025 gramme ( $\frac{3}{8}$  grain) it produced in a guinea-pig weighing 400 grammes (6160 grains) a lowering of the temperature of  $2^{\circ}$  C. ( $3.6^{\circ}$  F.) in fifteen minutes, and of  $5^{\circ}$  C. ( $9^{\circ}$  F.) in the course of two hours. This thermic depression was accompanied with bilateral tremors, inco-ordination of movements, collapse, stupor, and somnolence. A few days afterwards the same animal succumbed to a dose of .05 gramme ( $\frac{3}{4}$  grain), death being preceded by epileptiform convulsions and all the phenomena of asphyxia. Quinopropyline is probably about four times as poisonous as quinine.

*Therapeutic Uses.*—This medicament (quinopropyline) possesses also powerful antipyretic and antiperiodic virtues. As an antipyretic especially, quinopropyline produced excellent results in the treatment of a case of typhoid fever. It was given in doses of .50 gramme ( $7\frac{1}{2}$  grains) from the third to the eighth day of the disorder, causing a gradual fall of the bodily temperature from  $40.3^{\circ}$  to  $37.4^{\circ}$  C. The action of the agent is decided, and single doses of .50 gramme ( $7\frac{1}{2}$  grains) almost always produced buzzing in the ears, vertigo, nausea, and general malaise.

From the above study, the author concludes that quinethyline is superior to quinine as an antiperiodic, that it can be used with advantage where the latter drug fails to act, and that quinopropyline may be employed as a powerful antipyretic in continued fevers.

#### METALLIC IODINE IN THE TREATMENT OF TUBERCULOSIS.

CADIER and L. JOLLY (*Journ. de Médecine de Paris*, June 17, 1894) report their further experience in the treatment of tuberculosis by metallic iodine associated with the phosphate of iron and the glycerophosphate of potassium. The first combination was given in wine, each spoonful of which contained 10 centigrammes (1.5 grains) of glycerophosphate of potassium and 25 milligrammes ( $\frac{3}{8}$  grain) of iodine. The second combination was administered in the form of pills, each one of which contained 25 milligrammes ( $\frac{3}{8}$  grain) of iodine and 4 milligrammes ( $\frac{1}{8}$  grain)

of iron phosphate. The first week only two spoonfuls of the wine were allowed, and during the second week two spoonfuls of wine and two of the pills, to make up 4 spoonfuls of wine and 12 pills a day, representing in all 40 centigrammes (6.1 grains) each of iodine and glycerophosphate of potassium, and 5 centigrammes ( $\frac{1}{8}$  grain) of iron phosphate. These quantities never caused noxious effects, not even in patients who had previously suffered from hemorrhage. The number of cases observed was twenty-six during a period of from three months to two and a half years. During the first months there occurred an appreciable amelioration of the local lesions in the larynx as well as in the lungs. In from five to six weeks of treatment the appetite was considerably increased and the patients felt stronger. After from four to five months the amelioration of the local lesions was rapid and marked and the weight of the patients increased. During a period of from ten months to two and a half years there was a progressive and simultaneous amelioration of the local lesions and the general condition of the patients. The râles diminished gradually and the general health was much improved. Three of the patients resumed their usual work, and, notwithstanding the inevitable attack of grippe of that winter, no new untoward phenomena were observed on either larynx or lungs.

#### SPARTEINE IN CHLOROFORMIZATION.

In an interesting communication to the Société de Biologie, P. LANGLOIS and MAURAUGE (*La Nouveaux Remèdes*, August 8, 1894) call attention to the fact that sparteine, associated with morphine, is a powerful stimulant to the heart during chloroformization. The authors first experimented upon rabbits and dogs. Chloroform was administered to these animals while under the influence of sparteine, and although the anæsthetic caused an arrest of respiration, the heart, disturbed at first, rapidly resumed its normal rhythm. On the sparteinized dog, the arterial pressure remained high even during a profound chloroform narcosis. Sparteine was then tried in the human being. A dose of from 3 to 4 centigrammes ( $\frac{1}{2}$  to  $\frac{3}{4}$  grain), associated with 1 centigramme ( $\frac{1}{6}$  grain) of morphine, was injected hypodermically fifteen minutes before the administration of chloroform in various long surgical operations like laparotomy, hernia, etc. In one hundred and twenty observations made, the heart continued to act strongly and in a perfectly regular manner during the chloroform narcosis.

**DANGERS OF INTERNAL ANTISEPTIC MEDICATION.**

P. DIGNAT (*Journ. de Médecine de Paris*, July 1, 1894), in a timely article, writes of the dangers accruing from the internal administration of antiseptic remedies. He describes in detail two cases in which the ingestion, respectively, of salol and guaiacol, in comparatively feeble doses, produced a series of untoward symptoms. After a careful observation and study, these symptoms could only be ascribed to the action of the remedies alluded to. The author believes that antiseptic internal medication renders good service, but insists that the fact that such medication is apt to do more harm than good in many instances should not be lost sight of in modern therapeutics.

**THE DIURETIC ACTION OF CALOMEL.**

SKŁODOWSKY (*Deutsch. Archiv f. Klin. Med.*, 52, 1894; *Journ. de Médecine de Paris*, July 8, 1894) affirms that as a diuretic calomel acts in renal disease better than in cardiac troubles. In seven out of fourteen cases of well-defined Bright's disease, accompanied with œdema, calomel was found superior to all other diuretics recommended to-day. In summing up his experience, the author believes that calomel acts as a powerful diuretic, facilitating the disappearance of œdema in kidney-disease, with the important advantage that the drug does not produce noxious effects at all on the renal tissue. He believes that calomel ought to be tried where other diuretics have failed to act.

**THE TREATMENT OF CYSTITIS IN THE FEMALE.**

The treatment of acute and chronic cystitis in the female is clearly dealt with by A. LUTAUD (*Journ. de Médecine de Paris*, July 22, 1894).

*Acute Cystitis.*—In this form the first indication is to combat pain. The author recommends the following suppository:

Morphine hydrochlorate,  
Cocaine hydrochlorate, of each, .01 gramme ( $\frac{1}{10}$  grain);  
Extract of belladonna, .005 gramme ( $\frac{1}{40}$  grain);  
Cacao butter, 3 grammes (46 grains).

This suppository is introduced every four hours, until the pain and tenesmus ceases. For insomnia this rectal injection is advised:

Chloral hydrate, 4 grammes (60 grains);  
The yolk of an egg;  
Water or milk, 150 grammes ( $4\frac{3}{4}$  fluidrachms).

For general treatment, hot fomentations, poultices, and sitz-baths are recommended, as is also the introduction into the vagina, morning and evening, of the following tampon:

Camphorated lanolin, 30 grammes (462 grains);  
Extract of belladonna, 2 grammes (30 grains).

*Chronic Cystitis.*—When the pain and inflammation have subsided, an elastic or glass catheter, to which is attached a syringe holding 100 to 150 grammes ( $3\frac{1}{4}$  to  $4\frac{3}{4}$  ounces), is introduced into the bladder and the following injection put in:

Boric acid, 40 grammes ( $1\frac{1}{4}$  ounces);  
Biborate of sodium, 5 grammes ( $1\frac{1}{4}$  fluidrachms);  
Distilled water, 1 litre (1.76 pints).

Of this solution from 30 to 50 grammes (1 to  $1\frac{1}{2}$  ounces), according to the irritability of the bladder, are injected. This is followed by the injection of 150 grammes ( $4\frac{3}{4}$  ounces) of warm water holding in solution the following mixture:

Powdered iodoform, 30 grammes (462 grains);  
Glycerin, 40 grammes ( $1\frac{1}{4}$  ounces);  
Distilled water, 20 grammes (5 fluidrachms);  
Gum tragacanth, .25 gramme (4 grains).

Buchu and pichi are of service in the general treatment, and if pus exists in the urine, the following prescription is advised:

Benzoic acid, 1 gramme (16 grains);  
Orange-flower water, 50 grammes ( $1\frac{1}{2}$  ounces);  
Boiled water, 900 grammes (30 ounces);  
Sugar, 100 grammes ( $3\frac{3}{4}$  ounces).  
Of this a glassful is to be taken between meals.

Of course, the treatment must be modified according to individual cases.

**THE TREATMENT OF ICTERUS DUE TO RETENTION.**

Continuing his observations on the above subject, DUJARDIN-BEAUMETZ (*Bull. Génér. de Thérapeutique*, May 15, 1894) believes in treating such cases by thorough intestinal antiseptic measures. Of the drugs used for the purpose, such as salol, benzonaphthol, and the salicylates, the author favors the salicylate of bismuth, and he considers asaprol even superior to the latter remedy. A medicament that has rendered good service is calomel, which, according to the writer's experience, acts as a purgative and antiseptic at the same time. Care should be taken, however, in administering it for a long time, lest ptialism is produced. The author insists that bismuth salicylate and asaprol, and particularly laxatives

and a hygienic alimentation, constitute the best treatment for icterus due to retention. Among the laxatives mention is made of podophyllin, cascara, and cascarrine. Of mineral waters, those of Rubinat, Carabana, and Villacabras, in Spain, are recommended. Carlsbad salts are also spoken of as of service in the malady under consideration, being said to cause liquid stools without determining colicky pains or intestinal congestions. Diet must be mainly of a vegetable nature. When the gastric disturbance is marked, the ingestion of diastase is of advantage, and this should be given preferably after meals. Lastly, Vichy and Carlsbad waters are thought to exercise a curative action, by influencing the activity of the liver and causing an amelioration of the nutrition in general.

#### PILOCARPINE IN MÉNIÈRE'S DISEASE.

Three cases of Ménière's disease are reported by LABIT (*Rev. de Laryng., d'Otolog., et de Rhinologie*, September 1, 1894), in which the hypodermic use of pilocarpine gave satisfactory results. In one of the cases the hearing was improved only; in the other two, typical cases of the disease (one a fireman and the other a cook, in both of whom the heat to which they had been subjected brought about a congestion and a final hemorrhage into the labyrinth), the good effects of the drug were unmistakably manifest, as shown by a careful functional examination of the ear before and after treatment. The author believes that of all the treatments employed in Ménière's disease, such as the ingestion of the sulphate of quinine, iodide of potassium, the application of electricity, etc., that of the subcutaneous injections of pilocarpine is one of the most rational. The disorder is caused in the majority of cases by a sudden hemorrhage into the labyrinth, producing directly irritation or compression of the peripheral terminations of the acoustic nerve and of those of the semicircular canals. Since it is a well-established fact that pilocarpine, employed hypodermically, renders good service in pleuritic and peritoneal effusions, as well as in general exudations, it is reasonable to suppose that a similar action of the drug is exercised in like affections of the middle ear. The results obtained in the three cases reported seem to bear out this belief. The medicament was given in daily doses of from  $\frac{1}{4}$  centigramme ( $\frac{1}{24}$  grain) to  $1\frac{1}{2}$  centigrammes ( $\frac{1}{4}$  grain), and even as high as 2 centigrammes ( $\frac{1}{3}$  grain). These injections were generally followed by sialorrhoea and profuse diaphoresis.

#### CRUDE PETROLEUM IN PULMONARY TUBERCULOSIS.

In a communication to the *Bull. Génér. de Thérapeutique* of May 15, 1894, PELLISSIER, of Roumania, affirms that he has used crude petroleum from the vicinity of Campina, Roumania, in the treatment of pulmonary tuberculosis, with asserted good effect. In fact, he gives the drug to all his tuberculous patients, almost as a routine practice. He administers it in capsules, as it is obtained from the well, after subjecting the remedy to a simple filtration through filtering-paper. The patients are also made to inhale the air charged with the vapors of the drug, as met with in the wells, by means of a simple apparatus resembling a long Turkish tobacco-pipe. The results are said to be most satisfactory: the cough stops, appetite and sleep return, and the pulmonary lesions are cured, without any gastric disturbances being produced. The breath of the patients thus treated acquires the odor of the petroleum. The author has tried the same substance by rectal injections, but believes that the absorption is incomplete.

#### TREATMENT OF DIPHTHERIA.

DR. JULIUS RITTER (*Therapeutische Monatshefte*, July, 1894) first discusses immunized serum in the treatment of diphtheria. In 1890 he rendered animals immune to diphtheria by graduated injections of weakened cultures, and then successfully employed serum from these animals to protect guinea-pigs and rabbits. A large dog was by degrees rendered so immune that it received without decided reaction a quart of a virulent culture. Two weeks later its serum was so strong that eight cubic centimetres of it protected guinea-pigs of about five hundred grammes' weight from infection with virulent cultures of diphtheria bacilli; its immunizing value was, therefore, as 1 to 62,500. Yet this serum failed to protect a child which had been exposed to diphtheria, the child dying ten days after injection and on the fifth day of the disease. Of twenty-six children who received local treatment and the protective injections, twenty-one recovered, two of these after tracheotomy. It then seemed desirable to employ human serum. An opportunity was afforded by the abortion of a woman three weeks after an attack of diphtheria. After sterilizing the birth-passages, Ritter obtained a quart of blood, from which he prepared serum. In guinea-pigs the serum had a protective value of 1 to 80,000. It was employed in the case of six children with beginning laryngeal involve-

ment; but, in spite of it, tracheotomy was necessary in four cases, and two died.

Ritter seems to think that in diphtheria we have to do with a mixed infection, and that the great liability of some persons to repeated attacks—he has attended one child four times in four years—is against the lasting value of the serum treatment.

Assuming that the serum treatment has not fulfilled expectations, he asks what remedies should be used. All those which possess anti-septic without toxic properties. He recommends that the initial focus of the disease, in the shape of a tonsillar plaque, should be scraped off. He would employ anæsthesia if it seemed necessary. The surface from which the membrane has been torn is then touched with a one-per-cent. cyanide of mercury solution. In some cases this has to be continued, with expression and squeezing of the tonsils, so that no concealed focus may be overlooked. The posterior pharyngeal wall should also be closely inspected. If no more membrane can be discovered, the raw surfaces should be painted with impure oil of turpentine. Subsequently the remaining spores are destroyed by daily repeated painting with oil of turpentine and spraying with one-per-cent. cyanide of mercury solution. Sixty-two patients so treated, who presented membrane in the pharynx without secondary affections, were all, under this treatment, in a short time freed from all their disease symptoms. Thirty-three patients who presented themselves early have never shown post-diphtheritic palsies. The existence of diphtheria was in each case established by bacteriological examination.

The majority of local remedies in diphtheria are inactive, including chlorate of potassium and one- and two-per-cent. solutions of carbolic acid. Papayotin dissolves the membrane, but has no effect on the bacilli.

Cases of diphtheria complicated with streptococcus invasion are best treated with crude turpentine oil locally and large doses of alcohol internally.

#### THE TREATMENT OF ACUTE PLEURISY.

In a critical review of the subject stated above, DUJARDIN-BEAUMETZ (*Bull. Génér. de Thérapeutique*, August 15, 1894) points out those parts of the treatment in which the profession appears to be in accord, and these are: general bloodletting; wet cupping, as an efficient means of diminishing pain in the early stages of the disease; and thoracocentesis, although practitioners differ somewhat as regards

the quantity of liquid to be extracted at one time. The widest divergence of professional opinion, however, exists with reference to the administration of internal medication and the application of revulsive measures. As to the first, for instance, some practitioners recommend the use of the salicylate of sodium and salol, while others totally condemn such therapeutics; the same may be said in regard to blistering. Thoracocentesis is admitted by all as a proper means to employ, especially in cases where the pleuritic effusion is considerable, causing displacement of the heart, dyspnoea, and even threatening the patient with sudden death. The author favors thoracocentesis, but insists that a proper medical treatment, unless it be in urgent cases, should always precede surgical interference. Without referring to internal medication, in which he has but little faith in these cases, he believes in revulsive measures, and considers blistering the best mode of applying such measures. The local applications of tincture of iodine and of the recently introduced remedy, guaiacol, which has the peculiar property of reducing the bodily temperature when thus used, should be considered as of secondary importance in the treatment of uncomplicated cases of acute pleurisy. A similar treatment is advised for chronic cases in which adhesions have already been established. In this kind of revulsion, the author upholds the views entertained by Galippe regarding cantharides and cantharidine, believing these remedies to exercise a decided influence over inflammatory phenomena. The treatment, as indicated, may be modified, however, to suit individual cases. For instance, in diaphragmatic pleurisies, in which dyspnoeic disturbances and pain are most marked, the subcutaneous administration of morphine is indicated, producing good results, although the drug does not directly affect the march of the disease.

#### INFILTRATION ANÆSTHESIA.

DR. C. L. SCHLEICH (*Thérapeutische Monatshefte*, September, 1894) writes upon a method of inducing local anæsthesia by over-distending the tissues with fluids. The injections are in sufficient volume to supersaturate the tissues, render them oedematous, and induce anæsthesia by interference with nerve conduction.

His solutions are as follows:

I. Solutions for very hyperæsthetic areas,—inflammation, suppuration, neuralgic parts:

1. Cocainæ hydrochlor., .2,  
Morph. hydrochlor., .025;  
Sodii chlor. steril., .2;  
Aq. dest. (steril.), q. s. ad 100;  
Adde acidum carbol. (five per cent.), gtt. ii. M.  
Sig.—Strong solution for infiltration anæsthesia.

Or,

2. Cocainæ hydrochlor., .1;  
Codeinæ phosph., .06;  
Sodii chlor. sterilizat., .6;  
Aq. dest. (sterilizat.), q. s. ad 100;  
Adde acidum carbol. (five per cent.), gtt. ii. M.  
Sig.—Strong solution for infiltration anæsthesia.

## II. Solutions for moderately hyperæsthetic areas; normal solution:

1. Cocainæ hydrochlor., .1;  
Morph. hydrochlor., .025;  
Sodii chlor. sterilizat., .2;  
Aq. dest. (sterilizat.), q. s. ad 100;  
Adde ac. carbol. (five per cent.), gtt. ii. M.  
Sig.—Normal solution for infiltration anæsthesia.

Or,

2. Cocainæ hydrochlor., .05;  
Codeinæ phosph., .06;  
Sodii chlor. sterilizat., .6;  
Aq. dest. (sterilizat.), q. s. ad 100;  
Adde ac. carb. (five per cent.), gtt. ii. M.  
Sig.—Normal solution for infiltration anæsthesia.

## III. Very weak solutions for extensive operations. (In use changing with the concentrated solutions):

- Cocainæ hydrochlor., .01;  
Morph. hydrochlor., .005;  
Sodii chlor. steril., .2;  
Aq. dest. (steril.), q. s. ad 100;  
Adde ac. carb. (five per cent.), gtt. ii. M.

In preparing the solutions the sodium chloride is heated to glowing and the water heated separately. Morphine and codeine lose their activity when heated. The solutions should be used cool,—59° F.

Powders of the salts can be prepared and subsequently dissolved in sterilized water when needed for use.

Of these solutions, the medicinal doses are: of I., 25 syringefuls; of II., 50 syringefuls; and of III., 500 syringefuls. In over three thousand patients, Schleich has always kept within these limits. Large doses of the cocaine-codeine solutions may be employed; of No. I. (with codeine), 50 syringefuls; of No. II. (with codeine), 100 syringefuls. The syringes are disinfected by frequent washings in equal parts of five-per-cent. carbolic acid and absolute alcohol. In three thousand cases no abscess or suppuration has resulted.

The parts are rendered anæsthetic to the first injection by spraying with ethylene chloride or ether spray. The scrotum, labia, anus, mamma, and throat must be carefully protected with glycerin, because the application of the ether here may easily cause burning. A small particle of cocaine or a drop of concentrated carbolic acid renders mucous surfaces anæsthetic for the first injection.

Schleich gives elaborate directions for the employment of his method of anæsthesia in the removal of tumor, in the operation for hydrocele, radical operation for hemorrhoids, abscess, furuncle, and whitlow.

Regarding the first, he says that in all operations requiring an initial incision through the skin, anæsthesia is begun by the establishment of a primary endermatic wheal,—that is to say, the canula must be thrust within the skin, under the skin only, so as to cover the slit; it must be introduced parallel with the surface. The injection produces a wheal the size of a five-pfennig piece, which is absolutely insensitive. Other injections are now made around the first. The thinner the skin the more easily it is rendered white by the injections. The line of wheals marks the line of incision. At right angles with this the injections are made again subcutaneously, and thus the tumor can be dissected without pain. As the wheal, when once formed, remains anæsthetic for twenty-five minutes, that time may be sufficient for extirpation and subsequent suture, otherwise anæsthesia must be reproduced.

## A CASE OF TUBERCULOUS EMPYEMA CURED BY INJECTIONS OF CONCENTRATED SALT WATER.

H. DUBIEF and A. BOLOGNESI (*Bull. Génér. de Thérapeutique*, August 30, 1894) gives the details of a case of tubercular empyema cured by injections into the pleural cavity of concentrated salt solutions. The patient had a marked history of alcoholism. As a consequence of a previous pleurisy, a purulent and tubercular empyema was developed which necessitated the practice of pleurotomy. After the operation was performed, the pleural cavity was repeatedly washed with the salt solution, with the result that a complete cure was effected in the course of two months, not even a trace of a fistulous opening having remained. The salt solution employed was made up as follows:

- Chloride of sodium, 5 drachms (20 grammes);  
Sulphate of sodium, 15 grains (1 gramme);  
Distilled water, 1.77 pints (1 litre).

The washings were well tolerated, and during their use the patient remained apyretic, felt well, and had a good appetite; the kidneys operated normally, and the increase of bodily weight kept on steadily until a complete cure was established by the expiration of the time referred to above. The authors do not give a thoroughly satisfactory explanation of how the salt arrested the tubercular development, but, with the happy results obtained in the remarkable case reported, suggest the utility of washing out the pleural cavity, as indicated, in cases of purulent pleurisy.

#### NATURE AND MANAGEMENT OF DIPHTHERIA.

SLAGLE, of Minneapolis, has for five years past employed in diphtheria, with the most satisfactory results, a saturated solution of sulphite of sodium to the fauces, early and diligently, either as gargle, spray, or with a soft brush, alternating it with the free application of sublimed sulphur (one the alternate hour), the sulphur applied either by an insufflator or brush (dry).

If the case has not been seen early, and the membrane is already considerable and does not readily yield to these applications, he sometimes supplements them with either a spray of peroxide of hydrogen or a spray of the following solution:

R Hydrargyri bichloridi, gr. ii;  
Glycerini, ℥ii;  
Aq̄æ, ℥vi. M.

It is remarkable how diphtheritic patients tolerate the mercurials and alcoholic stimulants. In nasal diphtheria these same solutions are to be diligently applied to the nares, either by syringe or brush.

As to the best general or systemic treatment, he has found nothing equally successful with calomel, sulphur, and sulphite of sodium combined in powders, as follows:

R Calomel, gr. vi;  
Sulphur,  
Sodium sulphite, of each, ʒss. M.  
Ft. chart. No. vi.

Sig.—One floating in a teaspoonful of water every three hours, and no liquid for half an hour after it.

This is to be followed by a teaspoonful of castor oil with 15 drops of turpentine, after all are given. These doses for a child of three years old and over; reduce the dose for infants. In the interval between powders, and after all are given also, give a teaspoonful of saturated

solution of the sulphite of sodium (every hour), and after the powders are all used and worked off (with the castor oil and turpentine), alternate the solution of sulphite of sodium with a teaspoonful of chloride formula, as follows:

R Potassii chloratis, ʒss;  
Ammon. muriatis, ʒi;  
Tinct. ferri muriatis, ʒii;  
Glycerini, ℥i;  
Aq̄æ, q. s. ad ℥iv. M.

This is only required in bad and anæmic cases. This has been Slagle's principal systemic treatment for five years past, and has proved very satisfactory, but is to be supplemented, of course, by the best possible hygienic conditions. Good, nourishing, and easily digested food (liquid), milk, animal broths, egg-nog, and after three days, in severe cases, alcoholic stimulants, or, better, tinctura nucis vomicæ and tinctura capsici, as follows:

R Tinct. nucis vomicæ, ʒii;  
Tinct. capsici, ʒss;  
Syr. prun. Virgin., q. s. ad ℥iii.

Sig.— $\frac{1}{2}$  to 1 teaspoonful every three or four hours.

For inhalation and disinfection he has found nothing better than the formula and methods suggested by Professor J. L. Smith, in the "Cyclopædia of the Diseases of Children":

R Ol. eucalypti, ℥i;  
Acidi carbolic, ℥i;  
Turpentine, ℥vi. M.

Sig.—2 tablespoonfuls in a quart of water in a broad pan, kept constantly simmering on a hot stove in the room of the patient.

We have been in the habit of abusing the stomach by harsh remedies in diphtheria, as much as the throat. We now know that it is of the utmost importance to maintain, so far as possible, the integrity of this organ, looking steadily to the appetite and digestion. If the stomach shows signs of weakening and revolt under our treatment, we must at once resort to rectal medication and alimentation, remembering always that a loathing or disgust for food is one of the very worst prognostics, as a fair appetite is one of the most favorable indications, in this affection.

As to the divisions or classifications of different forms of diphtheria which have been attempted by authors, notably by Morell Mackenzie, as (1) the simple catarrhal; (2) the typical; (3) the inflammatory; (4) the malignant; (5) the gangrenous (or putrid); (6) the chronic form, or into the fibrinous (or phlegmonous) and the septic (or malignant), there is evidently very little utility, except perhaps

to assist the student in diagnosis, excepting the especial form predicted upon the site or location of the pseudo-membrane,—viz., croupous or laryngo-tracheal diphtheria, which demands special forms of treatment and generally surgical assistance.

The main indications to be met, then, in the treatment of this affection seem to be :

1. To endeavor to retard or counteract the formation of the pseudo-membrane, and to dissolve and disinfect it when formed, thus endeavoring to prevent the entrance of the septic poison into the system.

2. Where it has become systemic, to endeavor to eliminate and counteract its effects by antizymotics, etc.

3. To support the system by tonics, stimulants, and nourishment.

4. To endeavor to prevent or combat the various sequelæ; and how this may best be accomplished the author endeavors to indicate by the teaching of representative men in the profession, as well as from his own personal experience, extending through a period of more than a generation of men.—*Northwestern Lancet*, July 15, 1894.

#### THE TREATMENT OF LARYNGEAL PHTHISIS.

After some general therapeutic considerations, LANGMAID, in the *Boston Medical and Surgical Journal* for July 19, 1894, speaks definitely of this subject. He points out that the means used in the treatment of the larynx consists in the local application of medicines, palliatives, and escharotics; surgical procedures, such as curetting ulcers, draining oedematous swellings by puncture and tracheotomy; the use of electrolysis has also its advocates.

The list of emollients and escharotics which have been used is a long one. We refer to some of these only which have retained their popularity after years of trial.

Lactic acid stands, perhaps, at the head of the list of local remedies. It is an escharotic, and it is claimed that it attacks only ulcerated surfaces. However this may be, it has certainly retained the confidence of those who have had the largest experience in treating laryngeal tuberculosis; it is used either with or without previous curetting. The application of the acid by simply brushing over the ulcers is not enough; it should be well rubbed in by means of a hard cotton pledget upon the end of a bent wire after the application of cocaine. The writer has seen suitable cases healed by it.

Menthol is of great value when used in a twenty-per-cent. solution in olive oil; its analgesic effects are of great service; it is not caustic; it seems to prevent and remove infiltration.

Iodoform, in the form of powder or by solution in ether, is sometimes very efficacious in relieving pain.

Resorcin, in eight-per-cent. solution, has its warm advocates; it certainly seems to diminish suppuration, and it can be safely used without the laryngoscopic mirror.

Some years ago morphine in glycerin was thought to be most useful in relieving dysphagia. The author, however, resorts to its use as seldom as possible.

Of the astringents, he prefers the acetotartarate of aluminum, which, in addition to its astringent properties, has remarkable antiseptic power.

The use of cocaine has been advocated as a remedy in excessive dysphagia. The writer has found that it soon loses its analgesic power and thinks it produces insomnia.

With regard to surgical procedures, he states that very remarkable cures have been effected by very vigorous curetting. When the oedema of the epiglottis and arytenoids is excessive, he frequently punctures, and feels sure that in quite a number of cases he has relieved dyspnoea.

Tracheotomy has been done to relieve dyspnoea and to rest the larynx.

The fact that cures by each method are reported would tend to show that topical treatment should be employed in every case of ulceration.

The treatment by caustics must be left to the skilled laryngologist, but if for any reason the assistance of such cannot be obtained, great comfort may be given the patient and his life may be prolonged by a harmless course of treatment which can be carried on by the sufferer and his physician. This treatment consists in the frequent cleansing of the lower pharynx and top of the larynx by an alkaline spray, thoroughly applied several times a day, and followed by the application of menthol in oil, as mentioned above. The programme may be varied by substituting from time to time the eighty-per-cent. resorcin or an astringent such as the aceto-tartarate of aluminum or iodoform in powder. The result of such treatment is some relief from cough and dyspnoea, perhaps healing of ulceration and diminution of swelling. The patient's comfort is secured because one great source of irritation is lessened or removed.

*NEW METHOD OF TREATMENT OF  
PULMONARY PHTHISIS.*

CARASSO contributes a lengthy paper to the *Medical Magazine* of July, 1894, and, after considerable discussion, concludes as follows:

1. The patient inhales the essential oil of peppermint in a continuous manner.

The simplest inhaler is a square linen handkerchief, one decimetre long, folded so as to form a small pad five centimetres by about two, which is held in place, below the nares, by means of two tapes tied at the back of the head or round the ears. In the latter case the tapes can be replaced by metallic supports like those used for spectacles, or by two elastic bands. The pad, which is changed as occasion requires, must be kept permanently applied, night and day, and only removed at meal-times. When the disease is not in an advanced stage, and still allows the patient to follow his occupation away from home, a piece of goose-quill containing some absorbent wool charged with peppermint can be held between the lips like a cigarette. 5 or 6 drops of essence of peppermint are dropped on the pad four or five times a day, and to avoid any irritant effect, especially in individuals with delicate skins, the alæ nasi are for the first few days anointed with vaseline. The patient is instructed to breathe deeply through the nose with the mouth closed, and to hold the breath as long as possible, so that the inspired air impregnated with the volatile oil of peppermint may remain in direct contact with the bronchial mucous membrane, the alveoli, and vomicae, and the air they contain.

The patient is then allowed a rest of ten to fifteen minutes, during which time he breathes in the ordinary way through the pad. Deep respiration is again resorted to, followed by a rest, and so on. As during the night the pad may not remain in position, it is well to pour 15 to 20 drops of the essential oil on the pillow every evening.

2. The patient at the same time takes the following creosote mixture:

Pure beech creosote, 8 grammes;  
Rectified spirits, 550 grammes;  
Glycerin, 250 grammes;  
Chloroform, 20 grammes;  
Essence of peppermint, 8 grammes.

1 tablespoonful every three hours during the day (after well shaking the bottle) in half a glass of sweetened water.

In case this should be too concentrated for the taste of the patient, the quantity of the water can be increased and the single dose divided into several. In special cases where there is in-

tolerance, it may be necessary to begin with 1 or 2 tablespoonfuls a day, gradually increasing to 4, or to have recourse to those substitutes for creosote which can be administered in large doses without drawback.

3. The patient is superabundantly fed. Milk in large quantities, according to individual tolerance, the daily quantity being increased, where possible, to 1 or 2 litres of sterilized or, at least, thoroughly well boiled milk. Meat prepared in various ways to suit the taste of the patient and invite the appetite. Generous wines, Marsala being specially suitable in daily doses of 400 to 500 grammes. The patient is surrounded with every care dictated by hygiene and confirmed by experience in the treatment of pulmonary disease, as regards the dwelling, the occupation, and the precautions to be taken now that the infectiousness of phthisis is an admitted fact. It is above all necessary to see to the immediate destruction of the sputa, so that the patient may not breathe a bacillus or spore-laden atmosphere and be exposed to reinfection.

The greatest vigilance is required to see that the treatment is scrupulously carried out, especially the continuous inhalation of the ol. menthæ piperitæ. Careless patients resort to all sorts of shifts to evade the inhalations, and the treatment may fail utterly for want of proper supervision. Unless special circumstances prevent it, it is necessary to continue the treatment for at least a month after the disappearance of the bacilli from the sputa and of the physical signs.

*TURPENTINE IN DIPHTHERIA.*

Professor George suggested the use of oleum terebinthinæ several years ago for diphtheria, on account of its antiseptic action upon the air-passages. It arrests fermentation and putrefaction and is very destructive to all forms of bacteria. The bronchial secretions are increased during its use, and without doubt its effect in croup is largely due to its local antiseptic action during its elimination from the system.

Turpentine cannot be advised as a certain remedy. The majority of cases will die in spite of any treatment, whether medicinal or surgical; but its employment is urged as an adjuvant to other treatment, given in extraordinary doses. It is useless to give a few drops hourly. It must be given in frequent large doses and persisted in as long as there is any chance whatever. A child two years of age

will take a teaspoonful every two hours without exhibiting any untoward symptoms whatever. The author has given it in nineteen cases and has had eleven recoveries.

Dr. Shimonek, of Milwaukee, has kindly reported two cases with one recovery; Dr. Malone, of the same city, four cases with two recoveries, making a total of twenty-six cases with recovery in fourteen, or about fifty-four per cent.—KELLOGG, in *Journal of the American Medical Association* for July 28, 1894.

#### CREOSOTE FOR PHTHISIS.

- R Creosoti (beechwood),  $\mathfrak{m}_{xxx}$  to  $\mathfrak{m}_{lxxx}$ ;  
Tinct. cardamomi,  $\mathfrak{f}_{iv}$ ;  
Glycerini,  $\mathfrak{f}_{ii}$ ;  
Alcoholis, q. s. ad  $\mathfrak{f}_{iv}$ . M.

Sig—2 teaspoonfuls in water after meals.

NOTE—To the glycerin add the creosote, then the tincture of cardamom and alcohol.

The above is used in cases of pulmonary tuberculosis presenting evidences of breaking down of tissue, or in which signs or symptoms of catarrhal processes in any portions of the air-passages are present, or in which there is continuous elevation of temperature, or intermittent or remittent fever exceeding  $99\frac{1}{2}^{\circ}$  F. The smaller dose of creosote is used at first, and the quantity gradually increased until 5 drops four times a day is reached as a maximum.—COHEN, in the *Polyclinic* for July 14, 1894.

#### TREATMENT OF CROUPOUS PNEUMONIA.

In the *Journal of the American Medical Association* for July 28, 1894, KERR writes on this topic, and, after some introductory remarks, states that recently some clinicians have given digitalis from the commencement of an attack of pneumonia, on the basis that the increased force of the cardiac contractions will tend to prevent or diminish pulmonary congestion; this is unnecessary. So long as the heart is doing its work well, it should be left to itself and attention devoted to other parts of the treatment, such as reduction of temperature, elimination of waste matter, maintenance of the patient's strength, etc.; but just as soon as there is any sign of the heart becoming weak, digitalis should be given in such doses and with such frequency as the case demands. An average dose for such purposes is 15 minims of the tincture every three hours, until there is some influence on the pulse, after which the dose may be gradually reduced.

Should the patient not come under observation until the venous system and right side of the heart are engorged to such an extent that there is too much blood for the ventricle to conveniently handle, the author does not know of any treatment that will give better results than the administration of digitalis and the simultaneous removal of blood by venesection. In plethoric persons the same line of treatment is preferable to the administration of the vasodilators and cardiac depressants, such as aconite or veratrum viride, a process that has been justified under the clap-trap phrase, "bleeding a man into his own veins," but which really means an effort to increase the capillary area and leave the tissues full of imperfectly oxygenated blood without diminishing the amount of blood that the right ventricle has to accommodate. As the systemic is quite distinct from the pulmonary circulation, an increase in the systemic capillary area will only relieve the resistance against which the left ventricle contracts by allowing a more ready flow of blood into the venous system, but will not diminish the current of blood that has to pass through the right ventricle and pulmonary capillaries in order that it may be properly oxygenated.

Digitalis frequently fails in the treatment of pneumonia, because its action is essentially on the nervous system, and this is often deranged by the effects of temperature and toxic agents, so as to be insusceptible to the influence of the drug. Under such circumstances the simultaneous administration of strychnine will frequently increase nervous sensibility, so that the effects of the digitalis can be obtained.

The writer protests against the indiscriminate use of digitalis, and urges that the condition of the pulse should be the guide. Unfortunately, the introduction of the thermometer, sphygmograph, and other mechanical aids to diagnosis have greatly supplemented the use of the fingers, and comparatively few of us can equal the physician of thirty years ago in interpreting the pulse. The thermometer and similar agents are invaluable in showing the existence of certain conditions; the fingers on the pulse show how the patient is being affected by the drugs. When we give as much attention to the pulse as did our predecessors, and view the condition of the pulse in its relations to morbid anatomical conditions and the changes which these are liable to undergo, then shall we be able to follow a more rational line of treatment and more frequently conduct our patient through a serious illness.

## PRESCRIPTIONS.

For gonorrhœa:

- R Copaibæ bals.,  $\mathfrak{m}\text{iv}$ ;  
Ol. santali,  $\mathfrak{m}\text{v}$ ;  
Ol. cinnamomi,  $\mathfrak{m}\text{i}$ .  
Ft. in capsul. No. I.

From 6 to 12 capsules to be taken in the day, one hour after meals.

For incontinence of urine:

- R Sodii benzoati, gr. xv;  
Sodii salicylati, gr. xvii;  
Ext. belladonnæ, gr. xxx;  
Aq. cinnamomi, q. s. ad  $\mathfrak{z}\text{iv}$ . M.

A teaspoonful to be taken four or five times a day.

Useful in sluggish conditions of the liver:

- R Podophyllini, gr.  $\frac{1}{4}$ ;  
Euonyminæ, gr. iss;  
Ext. belladonnæ, gr.  $\frac{1}{4}$ ;  
Pil. hydrarg., gr. ii. M.  
For 1 pill, to be taken at bedtime.

A good evaporating lotion:

- R Ammonii chloridi,  $\mathfrak{z}\text{i}$ ;  
Sp. rectificati,  $\mathfrak{z}\text{ii}$ ;  
Sp. ætheris,  $\mathfrak{z}\text{i}$ ;  
Acid. acetic.,  $\mathfrak{z}\text{iss}$ ;  
Aq. destill., q. s. ad  $\mathfrak{z}\text{xii}$ .  
Solve et M.

To be applied on lint in severe sprains, etc.

For ozæna:

- R Acidi carbolici, gr. xxx;  
Resorcin (crys.), gr. xlv;  
Glycerini,  $\mathfrak{z}\text{iss}$ ;  
Aq.æ, q. s. ad  $\mathfrak{z}\text{xii}$ . M.  
To be used as a spray.

—*Medical Press and Circular*, July 11, 1894.

TYPHOID FEVER, WITH SPECIAL REFERENCE TO TREATMENT BY ANTI-SEPTICS.

This much-discussed subject in therapeutics is considered by KOENIG, of Pittsburg, in the *Medical Review* for July, 1894. He details his personal experience, and tells us that creosote was first chosen by him as the remedy, but as it is often difficult to obtain a good article of this drug, and as it possesses a stronger and more disagreeable empyreumatic odor than guaiacol, it was soon displaced by the latter, the main and most valuable constituent of creosote.

During the year 1893 thirty-three cases of typhoid fever were treated by the writer with this remedy; in no case was there intestinal hemorrhage, and none died. The author is aware of the fact that upon this number of cases no absolute conclusions can be based;

but it is nevertheless true that the epidemic during which they occurred was not wanting in virulency, as the four hundred and seventy-three fatal cases—a percentage of thirteen and a fraction of the entire number reported—indicate.

The method pursued in administering the remedy was according to the following prescription:

- R Guaiacolis,  $\mathfrak{z}\text{ii}$ ;  
Glycerini,  $\mathfrak{z}\text{ii}$ ;  
Alcoholis,  $\mathfrak{z}\text{xi}$ . M.

Sig.—5 drops in whiskey and water every two hours.

It was the writer's custom to vary the dose of the remedy according to the age of the patient, or according to the tolerance manifested towards the drug. Occasionally not more than 2 drops were given, while not infrequently 6 drops was the dose. To insure perfect solution in the water with which it was given, it was directed that a teaspoonful of whiskey be placed in a small drinking-glass; into this the guaiacol was dropped, and from 2 to 4 tablespoonfuls of water added. In about three cases the drug was not well borne; in one it was necessary to discontinue its use entirely. This case—one of four in the same family—was strong evidence, to his mind, of the value of the guaiacol. While the three other members of the family attacked with the fever were practically well after the fourth week, the one in whom the remedy produced gastric disturbances necessitating its discontinuance, passed through a six weeks' course, and was even then in a more than ordinarily debilitated condition for a month or two.

In addition to the guaiacol, the author, as a rule, administers small doses of calomel,  $\frac{1}{10}$  to  $\frac{1}{16}$  grain three or four times a day, until a slight purgative action is induced, when it is discontinued for the time being. During the latter part of the disease, when constipation is the rule, the same remedy was again employed, and always with excellent result. One teaspoonful of whiskey was given with every dose of medicine, and when the vital forces became weakened larger amounts were resorted to.

High temperature was controlled by frequent cold sponging. One case treated in Allegheny General Hospital received antipyretics of the coal-tar class from the resident physician. The antipyretic action of this drug was very prompt and decided, but was followed by a condition of great prostration, bordering on collapse. After this experience the temperature was reduced by sponging, which calmed and quieted the patient at the same time that

the fever was reduced, and without prostration.

The diet was liquid, and consisted of meat broth, beef-tea, and milk, the latter usually diluted by one-half with barley-water. During the height of the disease, when no desire for food is manifested, very little nourishment is given. Under this antiseptic treatment the time to begin the administration of solid food becomes a matter of great importance. The observation was made a number of times that when the temperature dropped to the normal point, during the latter part of the third week, though the tongue still remained coated, if solid food was given a relapse, indicated by a return of the morning and evening elevation of temperature, occurred. This can, doubtless, be referred to the disturbing influence that solid matter in considerable amounts would exert while passing over the unhealed ulcers, and the greater difficulty experienced in keeping such intestinal contents in an aseptic condition.

In illustrating the typical course through which the majority of the patients passed, the author presented the temperature record of Mr. G. M., aged twenty-four, who came under observation and treatment about the beginning of the second week of the attack. For the first week after treatment was begun he had three or four loose passages each day, and therefore no calomel was given.

The result of these cases treated after this plan during the past year he thinks warrants him in believing the following conclusions justified:

1. The antiseptic treatment is the rational treatment of typhoid fever.

2. Under its use the course of the disease is greatly modified, tympanitis is prevented, the tongue remains moist throughout, delirium is rare, and the intestinal tract is placed in the best possible condition for the healing of wounds.

3. Small quantities of alcohol often repeated sustain the vital forces better, during the height of the fever, than albuminous or starchy food.

4. In private practice cold sponging is the best antipyretic and nerve sedative.

5. As the temperature under this method of treatment often becomes normal before the ulcers are healed, care must be observed in the administration of solid food. A perfectly clean tongue rather than absence of fever is the indication for solid food.

6. The cost of the medicine and whiskey during the entire course of the disease rarely exceeds five dollars, which is a factor of no little importance with many patients.

7. Guaiacol exerts no disturbing influences on any organ, except in rare cases, when a very irritable stomach may reject it.

8. It should be given day and night, and, in the form of the prescription before mentioned, may be gradually increased to 7 or 8 drops every second hour.

9. Guaiacol prevents the later toxine-poisoning, doubtless because of its action on the bacillus coli communis and other putrefactive germs in the intestines.

10. Guaiacol is non-poisonous in ordinary doses.

#### ACONITE.

M. BLACHE (*L'Union Médicale*) has been employing the tincture of aconite with benefit in the diseases of children, especially in catarrhal and spasmodic diseases of the respiratory apparatus. The following is his general formula:

Tincture of aconite, 5 to 15 drops;  
Tincture of belladonna, 4 to 10 drops;  
Syrup of Tolu, 2½ drachms;  
Distilled water, 4 ounces.

A small teaspoonful every hour.

In cases of cardiac trouble superadded to the respiratory, he prescribes—

Tincture of aconite, 5 to 15 drops;  
Tincture of digitalis, 6 to 12 drops;  
Syrup of codeine, 3 drachms;  
Mucilage julep, 4 ounces.

A small teaspoonful every hour.

As a sedative, he recommends aconite in eruptive fevers as an antipyretic, and in painful affections as an anæsthetic, his prescription being—

Tincture of aconite, 5 to 15 drops;  
Cognac brandy, 2 to 6 drachms;  
Mucilage julep, 10 ounces.

A small teaspoonful every twenty minutes.

These observations of M. Blache correspond with those of Dr. B. Yeo: "It is quite remarkable how a few doses of aconite will rapidly subdue the febrile attacks which are commonly associated with local inflammation or other disturbances of health in children and young people." The great value therapeutically of aconite in children's diseases has been ascertained by clinical experience, and is as yet imperfectly realized by the majority of practitioners.—*Medical Press and Circular*, July 11, 1894.

*IMPERMEABILITY OF HEALTHY VESICAL  
EPITHELIUM WITH REFERENCE  
TO DRUGS AND POISONS.*

MM. BOYER and GUINARD, operating on full-grown dogs, with all the precautions necessary to prevent injury to the bladder, have ascertained that that viscus can tolerate and keep unchanged, without any local or general physiological indication of absorption, the following alkaloids in fractions of grammes: Pilocarpine, .10; cocaine, .50; morphine, .15; veratrine, .05; arsenate and chlorhydrate of strychnine, .10.—*Provincial Medical Journal*, September 1, 1894.

*TREATMENT OF EPILEPSY.*

In the *Virginia Medical Monthly* for September, 1894, in an article on epilepsy, DREWRY states that he has found some excellent prescriptions for routine treatment, as follows:

R Potassii bromidi, gr. xx to gr. xxx;  
Sodii bromidi, gr. x to gr. xx;  
Ammonii bromidi, gr. v to gr. x;  
Potassii bicarb., gr. v. to gr. x;  
Liquor potassii arsenitis, gtt. iii;  
Sp. menth. pip., ℥v;  
Aque, f3ss. M.

Sig.—Take after meals in glass of water.

R Potassii bromidi,  
Chloral hydrat., of each, gr. xv to gr. xx;  
Strychniæ sulph., gr.  $\frac{1}{8}$ ;  
Ext. ergotæ fl., f3ss;  
Ext. digitalis fl., ℥j;  
Sp. menth. pip., ℥v;  
Aque, q. s. ad f3ss. M.

Sig.—Take in sufficient water after each meal.

R Potassii bromidi,  
Sodii bromidi, of each, gr. x to gr. xxx;  
Ext. ergotæ fl., gtt. v;  
Tinct. nucis vom., gtt. v;  
Atropiæ sulph., gr.  $\frac{1}{16}$ ;  
Sp. menth. pip., ℥v;  
Aque, f3ss. M.

Sig.—Take as in preceding.

R Sodii boras,  
Sodii bromidum, of each, gr. xxx;  
Aque, f3ss. M.

Sig.—Take in wineglassful of water three times a day after meals.

When there is maniacal excitement, the addition of cannabis indica or hyoscyne proves serviceable; the latter should be given hypodermically. In hystero-epilepsy, physostigma, combined with bromide of potassium, acts quite well in the author's hands. The systematic administration of chloral yields good results in petit mal.

*TREATMENT OF VAGINISMUS.*

In an article in the *Provincial Medical Journal* for September 1, 1894, MADDEN states that he has based his treatment of this state on certain reasons, and has found it most successful in these cases,—viz., first, the employment of constitutional nerve sedatives and tonics to allay the general neurotic condition; and, secondly, the application of local nerve-stretching to the affected parts. On the latter point the writer briefly recapitulates the steps of the local procedure which he has proved the efficacy of, and which he would, therefore, venture to recommend to other practitioners. First, then, the patient, properly prepared for an antiseptic vaginal operation, and the rectum and bladder evacuated, is to be etherized and placed in the ordinary left lateral semi-prone position; secondly, a large-sized bivalve vaginal speculum is to be introduced and the blades then fully expanded; thirdly, a tampon of antiseptic cotton or wool, saturated in boroglyceride, is to be passed in through the speculum, so as to fill its calibre from the vulva to the roof of the vaginal vault; fourthly, the speculum, still widely expanded, is to be forcibly withdrawn, so as to overcome the contractility of the parts and at the same time thoroughly stretch, or even slightly rupture, the affected nerve-fibres. In so doing some little abrasion of the vaginal walls may possibly be occasioned; but any hemorrhage therefrom will be sufficiently controlled by the tampon, on which counter-pressure should be made during removal of speculum, so as to retain the included plug in the vagina, where it may be left for at least twenty-four hours, and then at the same intervals replaced by other antiseptic tampons, which should be employed for the next week to maintain the patency of the passage. Immediately after removal of these tampons the vagina should on each occasion be thoroughly flushed out with some antiseptic injection. Finally, if at the end of a week any evidence of vaginismus or spasmodic contraction should still remain, then the same procedure may be again repeated, after which it will probably be found that the passage has regained its normal sensibility and capacity. In some exceptional instances that curative result may not be thus obtainable, and in such cases it may possibly become necessary to resort to the removal of any specially hyperæsthetic tissues in the vulva vaginal area, or else to some of the recent modifications of Sims's or Emmett's operations for vaginismus. These procedures will, however, be comparatively seldom required by gynecologists, who may adopt

the simpler and, according to the author's experience, generally effectual plan of treatment which he has described.

*REMARKS UPON THE MEDICINAL TREATMENT OF CHRONIC EPILEPSY.*

BONDURANT, after careful observations on a large number of epileptics, states that prominent among the many drugs which have been largely used is sodium borate, which has been the subject of extensive experimentation, both in this country and abroad, during some years past. It has been advocated as a substitute for the bromides in certain cases, and accredited with active antispasmodic virtues. He gave it at one time a quite extended trial in the wards under his charge, using it in a variety of cases in quantities of as much as 12 grammes daily, continued for several weeks without ill effect. It was usually given in solution in water, with a little glycerin added. The small doses—1 gramme three times a day—seemed without effect; 6 to 8 grammes a day served in many cases to reduce the number of convulsions, but exerted no marked influence upon the character of the convulsive seizures, nor upon the mental state of the patients. The appended table exhibits the results obtained in fourteen cases in which 6 grammes daily were given for thirty days.

Of the cases mentioned in the table the author gives, all except three show a reduction in the number of seizures; and in two of the instances in which the convulsions occurred more frequently while the borax was being used, a marked diminution in the number of attacks is noted during the thirty days succeeding the withdrawal of the drug. In no instance was any markedly favorable influence upon the physical or mental condition of the patient to be observed. In several cases not included in the table the borax showed absolutely no influence in checking the seizures. In two instances complications arose. In one patient, a white woman twenty-seven years of age, having one or two convulsions a month, the administration of 1.5 grammes of the drug caused vertigo and headache, which disappeared promptly upon withdrawal of the borax, to as promptly return when, after a few days, the borax was again administered. In the second case, a white female, fifty-three years of age, who had usually not more than four or five attacks yearly, three days' use of borax (2 grammes three times a day) was followed by a general urticaria-like eruption upon the skin;

this eruption disappeared when the borax was discontinued, but reappeared when the medicine was again given, this occurring three successive times. Then  $\beta$ -naphthol (.3 gramme) was given in connection with the borax, and no eruption appeared, although the borax and naphthol were continued for some weeks.

Hare, in his monograph, speaks quite enthusiastically of the action of acetanilide, placing it next after the bromides as an antiepileptic agent, and remarking that especially in chronic epilepsy is its influence most favorable; but with the class of patients we have to deal with the results so far shown are doubtfully favorable or entirely negative. One or two cases seemed to do rather better under its use than under the bromides. There is no dulling of intelligence among its effects; whenever the mental state seems at all affected, the change is for the better.

Phenacetin has given in our hands about the same results as acetanilide. It has been given in the same doses and to many of the same patients; no ill effects were noted. In most instances it seemed utterly inert.

With antipyrin the final result is scarcely more favorable than is the case with the two remedies above mentioned. In a majority of the cases no effect is produced. In one case the drug has acted injuriously; in two the effect has been beneficial; in one of these very markedly so. The drug has been repeatedly used in this case, with improvement in mental state and physical health, and diminution in number and severity of convulsive attacks in every instance; in this same case the bromides produce much mental dulness and usually increase the number of fits; borax, acetanilide, phenacetin,  $\beta$ -naphthol, and other drugs have been used without effect; so it would seem that in this one case antipyrin is of positive value.

No bad effects were seen in any instance. The drug seems well borne, and large doses (3 to 5 grammes daily) can be continued for many weeks without danger.

Peterson and others have spoken well of  $\beta$ -naphthol, the basis of its alleged good effect in selected cases being its action as an intestinal antiseptic, a certain small percentage of epileptic convulsions being, it is claimed, excited by the absorption of toxic matters from the intestinal tract. We have used the drug to some extent as an intestinal antiseptic in cases of epilepsy, as well as in other forms of disease and insanity, and with excellent results as regards the relief of the immediate symptoms of intestinal poisoning; it seems also to exert some favorable influence upon the course of the

disorder under consideration, as shown by a reduction in the number of convulsions greater in proportion than has been obtained with any one of the four first-named remedies.

The practice of bloodletting in the status epilepticus is by the majority of authors not mentioned, or only mentioned to be condemned. The very favorable results given by this procedure in the writer's wards, however, bespeak a further trial of venesection for the relief of this condition. Our present custom in dealing with the epileptic state is to give a full dose of chloral in the beginning of the attack, repeating it, if necessary, after two to four hours; if the convulsions are not checked, or persistently recur as the effect of the chloral wears off, a vein is opened and twelve to twenty-four fluid ounces of blood are drawn. The results under this treatment are all that could be desired.

To briefly summarize:

1. Borax, antipyrin, acetanilide, phenacetin, and many other alleged antiepileptic agents are, save in rare cases, without influence over the course of chronic epilepsy with insanity.

2.  $\beta$ -naphthol is occasionally beneficial, but probably not more so than catharsis.

3. The bromides will postpone the occurrence of the convulsions, but in most cases do more harm than good.

4. In dealing with the maniacal attacks, seclusion may be necessary. Sedatives should be employed very rarely, if at all.

5. The best single remedy in the status epilepticus is bloodletting. Of drugs, the most valuable is chloral.—*American Journal of Insanity*, July, 1894.

#### CASE OF PENNYROYAL-POISONING.

STEPHEN reports, in the *Provincial Medical Journal* for September 1, 1894, the following: On May 8, about 1 A.M., the reporter was called to see Mrs. C. On entering the house it smelt very strongly of what at first struck him as oil of peppermint; the patient was lying on her back, her face pale and pinched, mouth wide open, pupils widely dilated, body cold and clammy and almost pulseless. She was quite unconscious, and her breath smelt very strongly of this oily substance. She could only be roused to semi-consciousness with difficulty. She swallowed a pint and a half of strong hot coffee, which in a few minutes she vomited; the vomit smelt very strongly of the oil. She drank another similar quantity of hot coffee and again vomited. By this time she was showing symptoms of collapse, so the

writer gave her half a glass of Scotch whiskey neat; she began to ramble a little. Shortly after,—about ten minutes or so,—he gave her a pint of strong hot coffee to drink, followed in a few minutes by 30 grains of sulphate of zinc with a quarter of a teaspoonful of powdered ipecac, in some lukewarm water; this made her vomit, and then she collapsed. Artificial respiration was resorted to and kept up for twenty minutes; all the while she was being rubbed with whiskey on the legs, thighs, and abdomen. In about half an hour she was able to swallow, so he gave her another half-glass of whiskey, which revived her, and her pulse improved; she was then allowed to be quiet for an hour, and at the end of that time given 2 ounces of castor oil; this she vomited almost immediately and then collapsed. Artificial respiration was again employed and some whiskey and two pills (pil. coloc. cum hyoscyami, B. P.) given her. The pulse and general condition improved and she fell asleep, and the physician left at about 4.30 A.M. He saw her again at eight o'clock. The pills had operated and the smell of oil throughout the whole house was something stifling, but the patient was much improved. She got up towards afternoon and was able to move about the house on the following day, but was of course very weak. She was all right in the course of a week, but for quite that time her breath and skin, also her stools and urine, smelt strongly of this oily substance.

The cause of this condition was that the woman was not very strong and had had very bad times during previous pregnancies and confinements, and as she had passed her menstrual period about a week, she concluded she was pregnant, so, in terror of this, she went to a local herbalist and purchased an ounce of essence of pennyroyal, the whole of which she swallowed at once, except a few drops in the bottom of the bottle, with the view of bringing on menstruation, instead of which she produced the condition herein described.

#### IODOFORM IN TUBERCULOUS PHTHISIS.

A. FOXWELL (*Birmingham Medical Review*, July, 1894) has had considerable experience of the value of iodoform in the treatment of tuberculous phthisis during the last eight years, and on the whole he considers it the most satisfactory of all the antiseptic drugs which have been used in tuberculosis. He has examined his out-patient case-books for 1886, 1887, and 1888, but, of the many in-

stances in which iodoform was used as the main treatment he could only collect forty-six where the notes were kept with sufficient persistency to make them worthy of record. Of these, twelve were much improved, fifteen improved, eleven remained the same, and eight grew worse; that is, fifty-nine per cent. improved and seventeen per cent. grew worse. Of the twelve who much improved, six had reached the third stage, but only two of these had both lungs attacked, and only one among the fifteen who improved; eleven had reached the third stage, and seven had both lungs involved. Of those who grew worse, five had both lungs attacked, and three of these had reached the third stage. Of the eleven who remained stationary, seven had reached the third stage and five had both lungs diseased. From these statistics it appears that the advanced cases did as well as the early ones. This the author thinks to be due mainly to the favorable nature of the advanced cases, these being mostly cases of localized cavitation or those in which considerable fibrosis had occurred. The unfavorable advanced cases doubtless felt themselves too ill to stand the exhaustion of out-patient attendance. The usual prescription was one 1-grain pill, to be taken six times a day. The dose never exceeded that amount, and was occasionally less, the average being five grains daily. In three cases only were any symptoms of poisoning detected, and these were merely of a mild gastric nature. The author also tried the drug in conjunction with oil and tonics, and compared both classes of cases with those in which oil and tonics alone were used. The conclusion he arrived at after a three years' trial was that iodoform given by itself gave better results than any other drug or combination of drugs he had tried or seen tried. It soothed the nervous system of erethic subjects; it very greatly lessened cough and expectoration; it powerfully increased nutrition, the patients often becoming quite plump under its continued use; finally, there was as great, if not greater, improvement in the physical signs than the author has seen accomplished by any other mode of treatment, except that of climate and hygiene. Foxwell has since used iodoform for the cure of phthisis in some private patients and in some hospital in-patients, and his later experience fully bears out his previous impressions. As regards mode of administration, the author believes it to be always safe to begin with 2 grains *t. d. s.* If the patient has difficulty in steadily taking this small dose, it is useless to persevere any further with the drug. "Having satisfied yourself," says the author,

"by three or four days' treatment that the daily dose of 6 grains can be well borne, order it to be increased by two grains every other day till 30 grains are reached. Keep the patient to this daily dose for at least three months, and at a somewhat lower level (should all signs of activity have vanished) for three months longer." If the patient does not strongly object, he always advises its continuance for a year. Foxwell has usually limited himself to a maximum dose of 30 grains a day.—*British Medical Journal*, September 8, 1894.

#### CHLOROFORM DURING SLEEP.

The following case is of interest, as bearing on the question whether a sleeping person can be chloroformed without awakening. The reporter was asked to take two teeth out for a girl aged seven, and, as she is very timid and excitable, to give her chloroform. On going to her home he found her lying on her back in bed, sound asleep. Having poured about 2 drachms, probably more, of chloroform on a folded towel, he gradually brought it to about two or three inches from her mouth and held it there. She went on breathing quite quietly, and neither coughing nor making any unwonted movements. In a very short time she was so well under its influence that her hand fell down when raised and the conjunctiva was insensible to touch. She was then lifted out of bed, carried into another room, and laid on a sofa without her giving any sign of consciousness. On opening her mouth, however, she put up her hands and turned her head on the pillow. More chloroform was given, and almost immediately she was in a state of complete anæsthesia and the teeth were extracted. She was easily aroused, but almost momentarily fell again asleep, and slept for two hours. When she awoke she was much astonished to find that her teeth were out.

#### FERRATIN.

GERMAIN SÉE (*Presse Méd.*, August 25, 1894), in a communication to the Académie de Médecine, states that even after prolonged use ferratin causes neither gastric nor intestinal derangement in men or animals. It acts as a slight astringent without causing injurious stimulation, and it never causes the development of  $H_2S$  as the result of putrefaction in the intestine. Its local effect on the gastrointestinal tract shows itself constantly in restoration of appetite and improvement in the

quality of the stools. It is absorbed slowly, but animals weighing from five to seven kilos have had to take from five to twenty litres of milk in order to absorb the same quantity of iron as could be conveyed in .1 to .2 gramme of ferratin. The dosage should be so regulated that the intestine shall always contain an excess of ferratin which the organism can use according to its needs. There is no reason to fear the accumulation of an excess of iron in the organs; absorption and elimination appear spontaneously to balance each other. Ferratin is, therefore, in the first place, an alimentary substance, and can be employed in men apparently healthy or in children and chlorotic subjects, as the curative action is not interfered with by injurious secondary effects, as is often the case when ordinary ferruginous preparations are used. The dose of ferratin is from 5 centigrammes to  $1\frac{1}{2}$  grammes (1 to 22 grains) two or three times a day; each dose contains about seven per cent. of iron.—*British Medical Journal*, September 8, 1894.

#### TRACTION ON THE TONGUE IN HYSTERIA.

TH. BALDLE (*Gaz. des Hôp. de Toulouse*, July 28) has in two cases made very violent hysterical attacks cease by traction on the tongue, the organ being drawn with some force out of the mouth and kept in that position for some minutes. This procedure was successful when every other treatment had failed.—*British Medical Journal*, September 8, 1894.

#### THE ANTITOXIN TREATMENT OF DIPHTHERIA.

A certain degree of immunity to diphtheria, lasting for a comparatively short time, can be conferred on animals by inoculating them with attenuated cultures of the specific bacillus, or by injecting a suitable quantity of the serum of an animal who has suffered from the disease in some form which has conferred on it immunity. Since it is probable that the cessation of the pathological process of an acute specific disease—that is to say, recovery—is due to the production of a condition strictly analogous to, or rather identical with, acquired immunity, the suggestion was made that the acquisition of this desired immunity during the existence of the disease might be hastened by the introduction into the organism of a quantity of the serum of an immune animal. This principle has now been applied in the treatment of two dis-

eases,—tetanus and diphtheria. Some striking results have been reported in tetanus, but the question of the value of the method in this disease is not yet settled. The claims made on behalf of the treatment of tetanus by antitoxin have been much criticised in an adverse sense. These criticisms have been founded in great part on the small number of cases which have as yet been treated, since in a disease which is not invariably fatal only a long series of cases can eliminate the source of fallacy which would be found in a run of mild cases. In the case of diphtheria this source of fallacy is being rapidly eliminated. The number of cases now on record by German observers is very considerable. The results, on the whole, have been remarkably encouraging, and apart from statistics, the marked improvement noted in many cases within a few hours after the administration of the first or second dose has carried conviction to the minds of those who have had the opportunity of observing the cases.

The earliest published cases of diphtheria treated by this method were a series of thirty reported by Behring and Kossel in April, 1893. Of these, twenty-four, or eighty per cent., recovered. For various reasons, among others the difficulty of obtaining the serum, it was some time before the example of the discoverer was followed by other physicians, but in April, 1894, Ehrlich, Kossel, and Wassermann reported the results in two hundred and twenty unselected cases of diphtheria treated by the hypodermic injection of the serum of goats rendered immune by giving them increasing doses of dead diphtheria cultures. Among the one hundred and fifty-three cases which it was not necessary to submit to tracheotomy, the mortality was only 23.6 per cent. In six treated on the first day there was no death, and in sixty-six treated on the second day there were recoveries amounting to ninety-seven per cent., whereas in twenty-three treated on the fourth day the percentage of recoveries fell to 56.5 per cent. In half the fatal cases the disease was so far advanced as to make recovery almost hopeless when the treatment was commenced, and in some other instances the stock of serum ran out. It is important to add that in a few instances the great improvement noticed in the first two days was not maintained, and the patients died in ten days or a fortnight of nephritis or cardiac failure. Nevertheless, Ehrlich and his co-workers believed that they had reason to hope that the serum treatment would eventually diminish the number of cases in which nephritis and paralysis occur as complications. The results in the cases submitted to tracheotomy were not so

favorable, the mortality being 44.9 per cent. The results of the treatment reported by Weibgen, from Hahn's clinic in Berlin, are not very conclusive: The number of cases was sixty-five. Of the patients submitted to tracheotomy, forty-four per cent. recovered; of the others, seventy-two per cent. The epidemic, however, was of a mild type, and by other methods of treatment the rate of recovery had been so much improved that in 1893 it had reached sixty-three per cent. among the cases not submitted to tracheotomy, and forty per cent. among those who did undergo the operation. The results in the Emperor and Empress Frederick's Children's Hospital are the most striking, the mortality, which had been over forty-one per cent. for fourteen months previous to the adoption of the serum treatment, falling, according to Katz's report, suddenly to 13.2 per cent., the number of cases being one hundred and twenty-eight. Weilgers saw his mortality fall from fifty-three to twenty-eight per cent., the number of cases treated with the serum being sixty-three.

There is some evidence that a person may be rendered immune to the infection of diphtheria by preventive inoculations. Klemensiewicz and Escherich have found that guinea-pigs can be rendered immune to diphtheria by inoculation with the blood-serum of patients just recovered from the disease. Wernicke succeeded in producing a certain degree of immunity in dogs by feeding them on the flesh of sheep which had been rendered refractory to diphtheria. The immunity in either case was of short duration, but Wernicke's observation that the immunizing principle is present in the tissues and can be absorbed from the intestinal canal is of great interest, and appears to open up a new method of administering the remedy comparable to the thyroid-feeding in myxoedema which has now so generally replaced the injections of thyroid extract at first. Wernicke succeeded in rendering his dogs more immune by inoculating them with increasing doses of the virus contained in old cultivations of the diphtheria bacillus, and he found that the serum of these dogs had so high a protective power that it rendered guinea-pigs immune to infection by a dose ten to fifteen times as large as was necessary to kill an unprotected animal. He found also that injections of the serum of these immunized dogs could bring about the recovery of guinea-pigs inoculated twenty-four hours previously with a fatal dose of the diphtheria bacillus. Katz inoculated seventy-two children exposed to the disease; only eight contracted it, and all of these recovered after a mild attack.

In the current number (September 3) of the *Berliner Klinische Wochenschrift*, Behring publishes a paper, in which, among other points, he deals with the question of dose. He states that the serum prepared and tested under his own supervision and that of Ehrlich is now issued in two forms,—No. 1 and No. 2; No. 2 is two and a half times stronger than No. 1. No. 1 is sufficient for the treatment of a case of diphtheria in a child under ten years of age, if it be seen on the second or third day. In cases of longer standing, in those of a very severe type in young children, and in adults a repetition of the injection will be necessary. No. 2 serum acts more surely and rapidly in these cases, but, owing to the difficulty of rendering the animals sufficiently immune to provide a serum endowed with immunizing powers so strong, a constant supply cannot be insured.

The estimation of the exact strength of the serum is a difficult matter, and it must be recognized that the strength is liable to vary with the commercial source from which it is obtained. Behring and Ehrlich have devised a method of expressing the strength in figures. Their No. 1 (quality and quantity) contains ten cubic centimetres, which is equal to six hundred antitoxin normals, and is sufficient for one case, with the limitations already mentioned. No 2 contains 11.5 cubic centimetres of a strong serum, and is equivalent to about fifteen hundred antitoxin normals. Behring now estimates that the death-rate of cases treated within forty-eight hours of the onset of the disease with No. 1 ought not to exceed five per cent.

The dose to be injected as a prophylactic in persons liable to be exposed to diphtheria is set down by Behring at 60 antitoxin normals, or  $\frac{1}{10}$  of No. 1. After infection—that is, during the incubation stage—he believes that 150 antitoxin normals ought to avert the development of the disease.—Editorial in the *British Medical Journal*, September 8, 1894.

#### NON-OPERATIVE TREATMENT OF HEMORRHOIDS.

GIBBS writes on this subject in the *Post-Graduate* for September, 1894. He makes no distinction between the two common varieties of piles,—the internal and external,—because the treatment of either answers for the other. There is a very painful little tumor frequently seen on the verge of the anus, very much the size and color of a huckleberry, consisting of a small thrombus in one of the marginal veins,

covered partly with skin and partly with mucous membrane. If let alone, the clot is absorbed and the tumor disappears, or else becomes infected, suppurates, and cures itself spontaneously; but in either case only after, perhaps, a week of suffering. In these cases the proper plan—and few patients will object—is to use a few drops of cocaine, laying open the cavity and pressing out the entire clot, thus curing the trouble and stopping the pain in half an hour or less. If, on the other hand, this little operation is not permissible, there is nothing to do but undertake three or four days' treatment, based on general principles, consisting in cathartics, preferably podophyllin or cascara, rest in bed, and cold or hot applications. Cocaine he has not found always satisfactory, though it does sometimes work to a charm. Among the wet applications, either hot or cold, his preference is for some preparation of witch-hazel or the common hospital lead and opium.

Last, and not least, is the time-honored suppository of opium and belladonna, so dear to the hearts of the medical profession. This is the recognized hospital treatment in New York and covers all cases of pain from any cause whatsoever, when the lesion is low down, in reach of the anus, but in severe cases rest in bed with catharsis accomplishes far more in a given time.

More painful still, and more difficult to handle, is that complication of marginal hemorrhoids known as fissure. It is most usually found posteriorly in the median line, overlapped by a fold of protruding hemorrhoid. Here, again, comes up the question of operation. For the most part when the writer finds a case of this sort that does not respond to the general treatment just laid down, he strongly advises giving ether, stretching the sphincter, cutting the fissure, and removing the hemorrhoids, thus radically curing at once an old chronic disease. Next best is the treatment already mentioned, when enforced as vigorously as possible.

Not infrequently these fissures heal quickly under local applications of nitrate of silver not stronger than 20 grains to 1 ounce, repeated not oftener than once in twenty-four hours; while, on the other hand, the solid stick is very apt to convert a small tear in the mucous membrane of the anus into a chronic, intractable ulcer. The temptation to use morphine in very severe, prolonged pain is great, yet the harm it does in these cases is not to be forgotten. Admitting the truth that constipation is the direct cause of acute symptoms in chronic rectal dis-

eases, we have no doubt in saying that a three or four days' course of morphine will reconcile almost any patient, no matter how timid, to either death or operation, after the first passage over an "intolerable" fissure. Verily, "constipation is the thief of time." A less frequent cause of pain, as a symptom of piles, may be seen when a mass of tumors prolapses and remains outside of the body, swollen, red, and perhaps gangrenous. Here the same procrastinating treatment will, in a week, more or less, help to diminish the acute symptoms. To summarize: In order of importance, rest in bed, unloading of the bowels, sensible diet, abstinence from alcohol, and an abiding faith on the part of the medical attendant that subsequent and severe attacks will induce a great sufferer to submit to an operation involving no pain or risk to life, with a guarantee of no more trouble.

The second symptom already spoken of is hemorrhage, usually accompanying the act of defecation, and varying from a few drops to an ounce or more. Most people do not bother with "a little thing like this," simply because it entails no pain.

On the first occurrence of bleeding, many patients are more or less frightened, until they have assured themselves that they have "nothing but piles," and let it run on indefinitely, except in those rare cases when the loss of blood begins to reach the point of exsanguination; but the majority of cases are allowed to continue or stop spontaneously. Hemorrhage, whether profuse or not, can be easily controlled, if the bleeding spots or area can be seen, by careful applications of nitric acid, or by touching with the Paquelin or galvano-cautery. There is no pain unless the skin margin is burned, and one application should be sufficient. Of course, any destruction of healthy mucous membrane does harm, and the cauterization should be superficial and limited to the bleeding-points or areas. Such cases as require etherization and ligation the author has read of, but not seen.

Prolapse of internal hemorrhoids occurs in advanced cases where the tumors are large and flabby. Whether they return to the cavity of the rectum with or without assistance after defecation, this symptom causes but trifling annoyance. It is not till the sphincter becomes somewhat relaxed and allows protrusion at any time, on standing or walking, that any real distress occurs, and this brings us back again to the subject of pain and what to do for it. In these severe cases local treatment is not very promising. Local applications or cauter-

ization, thorough reduction, and laxatives are worth trying, especially if re-enforced by a few days' rest in bed. If these fail, there is nothing but operation. Last and worst of all are cases of prolapsed hemorrhoids that refuse to be returned, become gangrenous, inflamed, and extremely painful. There is then absolutely nothing to do but rely on the rest cure and wait for the sloughing to destroy enough tissue to allow retraction and contraction.

The general principles already laid down are to be applied in the many nervous reflexes so common to all rectal diseases: symptoms referred to the bladder, urethra, ovaries, intestinal tract. After successfully quieting one or all of the symptoms of which we have spoken in such detail, there is nothing so useful as a local tonic as cold water applied to the perineum twice a day with a bath sponge; better than any suppository or astringent, used copiously, not inside the rectum, but outside of it. We have omitted all mention of carbolic-acid injections, for the reason that this method of treatment is in its true sense a surgical operation devised for the purpose of doing away with venous tumors, and liable to all the dangers and complications of cutting with knife and scissors, such as great pain, infection, abscess, sloughing to any extent, and secondary hemorrhage. Were we discussing operative measures it would have to take its chance with the ligature, the clamp, and the cautery. Summing up in a few words, the non-operative treatment of hemorrhoids comes down to general medication of some predisposing cause and local applications to relieve individual symptoms.

#### GLYCOSURIA FROM TAKING THYROID EXTRACT.

W. DALE JAMES (*Brit. Jour. Derm.*, June) reports the case of a medical man, aged forty-five, and an "old psoriatic," who had taken thyroid extract before Christmas without any effect on the disease, probably owing to the small doses swallowed,—one tabloid twice a day. On March 22, 1894, he began taking four tabloids daily, and at the end of a week complained greatly of depression, with frequent flushings and palpitations. The nervous symptoms increased, and the patient felt and looked a very old man. Before another week elapsed his thirst became unquenchable, the quantity of urine greatly increased, the breathing became embarrassed, the pulse rose to 132 per minute, and the smell of acetone was detected in the breath. On April 4 the urine had a specific gravity of 1032, and sugar was freely found by

all tests. The thyroid treatment was at once stopped and antidiabetic diet adopted. The quantity of sugar decreased daily, and on April 13 none could be detected. The general condition steadily improved, and on April 30 the patient was quite well, except for the psoriasis, which had not improved. Polyuria following the administration of thyroid has been noted more than once, but, as far as the author has been able to ascertain, this is the first case in which glycosuria has been caused by the treatment.—*British Medical Journal*, August 4, 1894.

#### THE TREATMENT OF SCIATICA.

GRAEME HAMMOND, in discussing the treatment of sciatica in the *Post-Graduate* for September, 1894, states that the pain of sciatica varies in accordance with the severity of the disease. In mild cases from 10 to 15 grains of phenacetin will afford prompt relief, but in the majority of cases the anæsthetic properties of this drug fall far below what the patient requires. If the pain is moderately severe or intense it is better to inject morphine. Enough morphine should be given in one dose, if possible, to thoroughly arrest the pain. It has been claimed that the morphine should be injected directly into the sciatic nerve, because it not only relieves pain, but also exerts a beneficial effect upon the inflammatory process. There is no proof that morphine possesses any such power. The writer has injected it repeatedly into the sciatic nerve in many cases, but never observed that it had any antiphlogistic properties. Puncturing the sheath of the nerve in a number of places by piercing it with a needle has in some instances afforded relief. This is accomplished by permitting the serum which is poured out between the sheath and the nerve to escape through the puncture made by the needle, thus relieving the pressure and consequently the pain.

Having made the patient comfortable, the neuritis is best treated in the following manner: Absolute rest of the afflicted leg cannot be too strongly advocated. Mild cases of sciatica sometimes get well in spite of this rule being flagrantly violated, but the course of every case will be shortened and, in many instances, the disease will be prevented from becoming chronic by the rule of absolute rest being strictly enforced. The patient should not only be confined to bed, but the leg must be made almost immovable by being confined in a splint. The author prefers the old-fashioned hip splint, as recommended by Weir Mitchell. A piece

of board about three inches wide and long enough to reach from the axilla to the sole of the foot should be properly covered, and then applied by attaching it to the body by a few turns of a bandage, and in the same manner to the leg from the knee to the foot and from the knee to the hip.

Having thus secured almost perfect rest for the inflamed nerve, the next most important feature of the treatment is the application of heat. The most common seat of the neuritis is in the upper part of the nerve, from its exit from the pelvis to the middle third of the thigh. Hot-water bags should, therefore, be placed under the back of the thigh and kept there continuously until all signs of inflammation have ceased; the constant electric current is also very serviceable in relieving pain. In almost all cases patients will speak of the improvement they feel after each application. A large electrode, fully the size of the foot, should be fastened to the sole of the foot by straps or elastic bands. Another large electrode, fully six inches square, should be placed under the hip while the patient is reclining. This electrode should be connected with the positive pole, the one on the foot with the negative pole, and the current should then be gradually turned on, being careful not to break the circuit until the patient is receiving enough to give rise to a moderate sensation of burning. The current may then be allowed to flow uninterruptedly for about five minutes, and should be gradually diminished until it is taken off entirely. This ought to be repeated daily, and in severe cases it can be used advantageously twice a day. By these three methods—absolute rest, continuous application of heat, and daily applications of galvanism—the most severe acute cases will promptly yield, the average cases not lasting longer than seven or eight days. At the end of that time treatment can be discontinued, but the patient should remain in bed two or three days longer. If, in that time, he can move the leg without pain, he may then be allowed to walk a little and to gradually increase the distance until further restriction becomes unnecessary.

#### *THE VALUE OF AN ETHEREAL SOLUTION OF IODOFORM IN THE TREATMENT OF HEMORRHOIDS.*

BECK contributes a paper on this subject to the *New York Medical Journal* of July 21, 1894. After considering the great absorbent power which iodoform dissolved in ether exerts in such conditions as cysts, lymphomata, goitre,

etc. (hydrocele, also, in which the writer has recently employed it successfully), where a shrinking process of the tissues is intended, he was induced to try its effect in the treatment of hemorrhoids, and the good results which he has obtained in eight cases encouraged him to recommend this remedy to the profession, although he is well aware that the small number of cases, as well as the short time which has elapsed since the operations were performed, may impair to some extent confidence in the new method.

The operation is done in the following manner: After having prepared the patient by cleansing the bowels thoroughly with repeated irrigations of a solution of salicylic acid about fifteen minutes before the operation, a suppository containing two grains of cocaine and from a quarter to a third of a grain of morphine is introduced into the rectum. If the patient is extremely sensitive at the beginning of the operation, a one-per-cent. solution of cocaine should be injected into different portions of the mucous membrane, but practically he has never found this to be necessary. It may predispose the patient to hemorrhage.

After the introduction of an iodoform-gauze tampon through a small speculum, the tumors are brought into view without grasping them with a forceps. Two drops of a saturated solution of iodoform in ether are then injected into the cellular tissue adjoining each nodule. Injecting this on both sides of the latter causes a formation of scar tissue and a shrinkage of the circumvenous tissue. If the cocaine-morphine suppository has been introduced at the proper time, the pain following this procedure is very slight and passes away in a few moments. In place of the gauze tampon, a suppository containing 2 grains of salicylic acid is now substituted, and bismuth and opium are given to prevent a movement of the bowels.

On the third day 2 ounces of olive oil are injected into the rectum, and castor oil is given per os. During the subsequent weeks great care should be taken to keep the bowels loose. This operation does not prevent the patient from attending to his daily work.

No bad effects have followed, such as sepsis, abscess, ulceration, embolus, hemorrhage, and stricture or fistula, and no relapse has yet occurred in any of his cases. If no obliteration but contraction should take place in a large hemorrhoid, he would repeat the operation.

The following advantages are to be derived from the injection of iodoform dissolved in ether: 1. The operation can be performed without assistance, thus materially lessening

the expense, which to many patients is an important item. 2. Iodoform, being a strong antiseptic, is certainly fitted to prevent supuration or possibly sepsis, and differs considerably from the much-used carbolic acid, which, if employed in the requisite strength, acts as a caustic. 3. As the nodules themselves are not touched, but only the circumvenous tissue, it is evident that embolism, which follows the use of carbolic acid and other liquids, cannot occur. (Death due to the injection of carbolic acid is by no means a rare occurrence. In a case of the writer's, after he had injected a ten-per-cent. solution of carbolic acid into three small nodules in a young woman, a temperature of 106° F. set in ten hours afterwards. On the following day icterus developed, but fortunately disappeared two weeks later, leaving the patient in a very weak condition for several months.) 4. No contraction takes place, such as follows the use of the cautery. 5. The patient can resume his work at once.

Seven months ago he used this treatment in the first case, five months ago in two cases, and four months ago in another case, and in all the hemorrhoids have disappeared. The four remaining patients, who are doing well, were treated between one and three months ago.

Beck has had no opportunity of employing this method in treating so-called thrombotic and capillary hemorrhoids, but there is no reason why it should not yield to it.

In one of the cases mentioned the patient had prolapsed and large tumors, and this injection was used with good results, although the sphincters were contracted. If he had failed, Whitehead's operation would then have been performed. Among the other cases, two of the patients had internal and five external hemorrhoids, and, although in two cases there was inflammation, the injections were well borne and successful.

From a strictly surgical point of view, Whitehead's operation is the ideal one. But it should not be forgotten that it can be done only when good and sufficient assistance is obtainable; furthermore, it confines the patient to his bed for at least two weeks. What this means to a poor workingman every physician knows, and in New York City, where, on an average, every fourth adult suffers from hemorrhoids, such points have to be taken into consideration.

In reference to their frequent occurrence, it may be said that it was quite customary in Germany to call hemorrhoids "the American disease" before America had enlightened the Old World about appendicitis, which is now hon-

ored with this term. There is some truth in this, for the busy and enterprising American citizen, in his haste to become rich, does not seem to pay sufficient attention to the ordinary laws of health.

Since writing the above article the author has operated in four other cases with the same good results. He has also tried the same injection in the circumvenous tissue in two cases who had suffered from varicose veins of the legs for twenty-seven years. Perfect recovery took place when he had injected at eight different points. In a case of varicocele in which he tried the injection in the same manner the result is still imperfect, probably because he used too small a quantity of the solution.

#### *A FEW APHORISMS RELATING TO OBSTETRICS.*

What to do and what not to do in the management of labor, that is the question.

No branch of a physician's practice requires more self-poise, and where so many complications arise, commanding our sympathy and demanding our skill, as that of obstetrics, and when disease and death follow a normal case of labor, the cause can be traced to none other than to ignorance or mismanagement.

With these preliminary remarks, Ewing advances a few aphorisms relating to obstetrics.

1. Examine the urine a week or so before the expected confinement. Albumin need not cause alarm, unless present in large quantity, in which case the woman should be restricted to milk diet, given  $\frac{1}{10}$  grain of sulphate sparteine four times a day, and bowels kept open with cream of tartar, the object being of course to relieve congestion of the renal veins.

2. Make no digital examination without first cleansing the hands and nails, together with the external genitals, with a solution of bichloride of mercury (1 to 2000) and ethereal soap.

3. Empty the rectum thoroughly with an injection of warm water.

4. Make as few examinations as possible during progress of labor, and each time dip the hand first in the antiseptic solution.

5. If presenting part emerges slowly from the womb, do not allow your impatience to so get the better of your judgment as to induce you to "assist nature" by pulling upon the os. Probably all the deep pathological tears, calling for surgical interference, found on the right and upper anterior sides of the cervix, are caused by the finger of the accoucheur.

6. If "pains" are sluggish, change the position of the patient.

7. Do not rupture the "bag of waters" too soon, as it, when intact, favors the posterior rotation of the face.

8. Should a posterior rotation of the occiput occur, and nature fail after a reasonable length of time to effect a delivery, apply the forceps and turn the occiput to the front by rotating either to the right or left, as the position of the babe would indicate. This manoeuvre of the forceps can be executed without danger if care be exercised, turning the head not more than a quarter of a circle at a time, then pausing a moment for the shoulders to follow. After this is accomplished the instruments should be removed and reapplied.

9. In making traction on the child's head with the forceps, unlock them about every thirty seconds, else the engorgement produced by continued pressure of the instruments might cause a hæmatoma of the brain or dura.

10. To prevent a rupture of the perineum.

When the occiput is emerging from the vulva, remove the right hand from the forceps and with it support the soft parts, while with the left you continue slight traction upward until the bridge of the nose reaches the anterior border of the perineum, when the instruments are quickly removed. Now, in order to avoid a rupture, especially if an expulsive effort is being made, hold the head in *statu quo* until a relaxation takes place; then, with the thumb and first two fingers of the right hand, push the perineum down and under the chin, allowing it to rest on the palmar surface of the fingers. The next pain will expel the head, which is grasped by both hands and pulled upward, delivering the under shoulder first.

11. Should a rupture occur, repair the injury at once, using the large iron-dyed silk.

12. Do not become impatient if the placenta does not follow quickly, but wait, say a half or even an hour, before an attempted forcible delivery is made. Should, however, a violent hemorrhage occur, empty the uterus at once, by disinfecting the hand, introducing it into the womb, detaching the placenta, and allowing it and the hand to be forced out together.

13. The source of uterine hemorrhage following labor arises almost always from the open and now no longer useful utero-placental vessels. Nature, ninety-nine times out of a hundred, prevents hemorrhage arising from this source by filling up these tortuous vessels and plastering over their open mouths with coagulated blood. Therefore,—

14. Do not use Créde's method, and for two

reasons: first, that the act of squeezing out the placenta dislodges at the same time from the anfractuositities and vessels this plastic coagulum, inviting streamlets of blood to follow the non-pressure of the hand, causing in all probability a hemorrhage instead of preventing it. The second reason is, that a hemorrhage following after this method of forcible expulsion, necessitating, as it usually does, a constant hand-pressure over the uterus for half an hour or more, while it may not prevent absolutely the reformation of nature's cement, would cause paralysis of the contractile fibres of the womb, rendering them incapable of responding to the stimulus of ergot or to anything else.

15. For these passive hemorrhages, where so soon as the hand is removed the hemorrhage goes on, the writer relies on 1 teaspoonful of laudanum rather than 2 or 3 of ergot.

16. After the birth of the child, gently knead the abdomen with the finger-tips of the left hand, using barely force enough to feel the uterus beneath. This gentle friction excites uterine contraction far better than rough massage, expelling the placenta almost as quickly, and is rarely, if ever, followed by unpleasant hemorrhages or after-pains. This slight finger-pressure should be continued a short time after the placenta is expelled.

17. In early abortions, before atrophy of the blood-vessels of the mucosa takes place, the hemorrhage comes greatly from this engorged mucous membrane instead of entirely from the placental surface, as in full term. To stop it, do not use ergot or compression, but approximate the inner surfaces by removing the decidua with the placental forceps and dull curette. This is to be followed by a hot antiseptic (preferably carbolic acid) intrauterine douche.

18. Have the vulva kept well covered with sublimated cotton to catch the lochia and prevent infection; and, in addition, if a clean and competent nurse is in attendance, order given night and morning, for five days, warm antiseptic vaginal douches.

19. Wash the babe's eyes the moment it is born, and in dressing the navel use borated cotton saturated with glycerin.

20. Restrict the diet the first three days only, after which have the bowels moved either by an enema or the compound licorice powder. (If there is much flatus, use instead a full dose of castor oil and turpentine.)

21. Keep the woman in bed two weeks, if possible, and the first four days give a capsule containing  $\frac{1}{2}$  grain of ergotin and  $2\frac{1}{2}$  grains of quinine, morning, noon, and night. This

tends to prevent fever and hastens the process of involution.

22. If surgery is your specialty, and you are called to a case of confinement, use extra precautions in cleansing the hand and nails; in fact, it would be wise, if your practice in surgery is extensive, to let obstetrics alone.—EWING, in *Medical Record*, July 21, 1894.

#### STIMULANTS.

In the course of an article upon "Feeding after Weaning," in the *Medical Record* of July 21, 1894, STOWELLS points out that the testimony of physicians is almost unanimous against alcohol for children in health. The small percentage of sugar or oxidizable material in wines and beer is more than offset by the injuries to digestion and the nervous system. All the best men use stimulants guardedly, even in infantile disease. Tea and coffee have a very considerable value in checking tissue waste, and indirectly supplying nitrogenous matter and salts; but these virtues are entirely counterbalanced by the ill effects of tannin and thein, the one causing colic, etc., the other making the child nervous, fretful, and peevish. Still, the children of the poor consume great quantities of both.

In regard to feeding, he says,—

In arranging a dietary, regard must be had for season, cold or hot climate, sluggish or active temperament of the child, etc. The exact weight or exact age of the child is not a proper criterion. Two atoms of hydrogen unite with one of oxygen to form a molecule of water; but you cannot be sure that a given number of grains of nitrogen will produce a definite number of foot-pounds of force, or that so much sugar will produce so many heat units.

It is often forgotten that the child needs a large amount of water, even if his diet be chiefly fluid.

The following dietary may serve as a basis for directions to parents and nurses:

#### FREQUENCY AND SUBSTANCE OF MEALS.

7 A.M. (a) Milk. (b) Milk and rusk.

10.30 A.M. (a) Oatmeal or barley in milk; sugar or malt. (b) Beef-tea.

2 P.M. (a) Egg in milk, sweetened. (b) Stale bread and milk.

5.30 P.M. (a) Milk and cracker or zweibach. (b) Milk and oatmeal or barley.

10 P.M. (a) Milk. Total milk, one and a half pints.

#### ONE YEAR TO ONE AND A HALF YEARS.

7.30 A.M. (a) Rusk or cracker and milk; (b) Soft-boiled egg; milk; orange.

11 A.M. (a) Milk; bread and butter. (b) Baked potato; milk.

2 P.M. (a) Beef-tea; light pudding. (b) Bread, butter, bread in meat gravy from a roast. (c) Meat, roast, to suck on.

5.30 P.M. (a) Bread and milk; prune juice. (b) Cocoa; custard.

10 P.M. (a) Milk, if awake. Total milk, two pints.

Two later periods in childhood deserve a moment's consideration.

At the sixth or seventh year, when the deciduous teeth fall, the child must be urged to chew his food thoroughly. If he begins to attend school, that will form an excuse for bolting meals.

Still later, at puberty, unusually rich or highly spiced food should be avoided, lest it increase sexual excitement in the immature.

Bring up the child from the beginning to eat slowly and at regular times as much as he wants. The rules of time and quantity will be on a sliding scale in different families. In feeding infants, as in the whole practice of medicine, we must fix the principles and prescribe with common sense, according to the case in mind.

#### THE MORPHINE HABIT.

In concluding an article on this subject in the *Montreal Medical Journal* for July, 1894, MANN states that the opium or morphine habit is a curable disease, and the writer only desires to know that an opium sufferer honestly desires a cure to assure him that this result can be accomplished. There is no disease that yields a better percentage of cures to the proper treatment. Primarily, the patient must put himself under the necessary control, and must desire a cure himself.

The nervous system of most persons is too delicate to bear the shock of a total deprivation of the morphine at once. Grave nervous disorders follow such a course. In the writer's plan of treatment he employs a reductionary course of treatment, keeping the patient's nervous system quiet with a combination of the bromides, gradually increasing the bromides as he decreases the morphine until, on the tenth day after admission, his patient is taking no morphine and has avoided all suffering and nervous prostration. For a tonic during this first period of treatment he uses the elixir of gentian with the tr. ferri chlor. He generally

combines the bromides of ammonium and sodium, and eliminates them from the system after he stops the morphine by warm baths, sweet spirits of nitre, and digitalis. The reflex action of the spinal cord, which has purposely been kept depressed by the bromides during the reductionary treatment, is now excited by strychnine, and the central nervous system is stimulated and invigorated by the daily use of the induced or faradic current of electricity as general faradization. To obviate any psychosomatic suffering after withdrawal, he uses nitro-glycerin ( $\frac{1}{100}$  grain) by the mouth, while at the same time he gives a hypodermic injection of  $\frac{1}{4}$  to  $\frac{1}{2}$  grain of sulphate of sparteine. He uses this for perhaps two or three days after complete withdrawal.

#### ECK'S OPERATION.

In the *Lyon Médical* for July 1 there is an editorial article signed by M. R. LEPINE, headed, "Is a Wound of the Portal Vein necessarily Fatal?" The writer remarks that the trunk of the portal vein, by which the blood coming from the spleen, the intestines, the stomach, etc., is conveyed, is, as it is well known, only a few centimetres long. On reaching the hilum of the liver it divides into two great terminal branches, one of which is directed to the right and the other to the left; according to Testut, these two branches look as if they formed but one vessel in the transverse fissure of the liver. M. Lepine does not hesitate to affirm that a wound of this vein, whether of the trunk or of one of these branches, is fatal unless it is a mere puncture. The circulation of blood in the portal vein is extremely active, even during a fast. Besides the great amount of blood which passes through the vein in a given length of time, we must take its tension into account; it is evident that the higher the tension, the orifice of escape being the same, the more considerable will be the amount of blood lost, on account of the greater rapidity of its flow. Now, the tension of the blood in the portal vein far exceeds the general venous tension, on account of the interposition of the capillaries of the liver.

In case of puncture, asks M. Lepine, is lateral ligation possible? If the puncture involved the trunk itself, he says, such a ligation might be attempted, in spite of the difficulty of its execution, and it is conceivable that it might save the patient. But the operation does not seem practicable upon either of the two branches. The absolute impossibility

of such a procedure when the wound of the vein is situated not on the free portion of the vessels, but upon that aspect which is hidden in the liver, will readily be understood. Let us suppose, the writer goes on to say, a large wound of one of the two terminal branches, let us premise that it is visible, and let us admit that it is possible to tie the vessel above and below the wound; this double ligation would certainly stop the bleeding, but it would also bring about, on the one hand, an interruption of the circulation in one of the lobes of the liver (that is to say, a suppression that could not be ignored of the function of a considerable portion of the organ); and, on the other hand, a notable embarrassment of the circulation in the portal vein (that is to say, a great increase in the volume of the spleen, extreme congestion of the intestinal mucous membrane, etc.). Could life be preserved, M. Lepine asks, with such derangement of the function of the liver and of the other abdominal organs? There is no experience upon which an answer to this question can at present be based. As to the sudden total interruption of the course of the portal blood by reason of compression or extemporaneous ligation of the trunk of the portal vein, it is incompatible with life. Dogs succumb to it in two hours, and sometimes much sooner. At the autopsy the mesenteric veins are found gorged with blood and the spleen is of colossal size.

If, in the case of ligation of the portal vein, death is owing in part to stagnation of blood in the splenic and mesenteric veins, would it be possible to avoid it by causing the peripheral end of the portal vein to form a junction with the inferior vena cava? Such an operation was proposed by Eck, a Russian surgeon, and quite recently Professor Queirolo, of Pisa, has materially perfected its technique in certain respects, and thereby rendered the operation comparatively so easy, at least in the dog, that, although not a surgeon, M. Lepine has practised it several times lately for a special purpose,—that of suppressing the physiological function of the liver. He describes the method as follows, saying that it is almost exactly that which Queirolo has described: An incision is made through the linea alba from the xiphoid cartilage to within a few centimetres of the pubes. The operator, stationed at the left, draws the intestinal coils out and to the left and exposes to view the inferior vena cava, which is tied between the abouchment of the renal veins and the junction of the common iliacs. At the point where the renal veins empty, the vena cava is compressed with a broad clamp, and it

is then cut between the clamp and the ligature. Then the vena porta is isolated and tied as near as possible to the hilum of the liver. At a point a few centimetres above a broad clamp is fixed and the vein is cut near the ligature; the lower end is inserted through a ferule shaped very much like a napkin-ring, and is folded back over the ferule in such a way that the lining membrane constitutes the exterior. The vein, thus disposed upon the ferule, is tied; then the whole is passed into the upper end of the vena cava and tied, so that there now remains nothing to be done but to remove the two broad clamps to cause the portal blood to flow into the vena cava. In consequence of the apposition of the lining membranes a solid scar might ultimately be formed.

Such, so far as regards its essential features, is this operation, which may easily be performed upon a dog in half an hour. Unfortunately, says M. Lepine, its results are generally fatal, so that, even if it has been simplified, Eck's operation still remains grave. The writer remarks that it would lead him too far to go into an analysis of the causes of death. Eck's idea, he says, was that the operation might be useful in certain cases of cirrhosis of the liver, but it is very doubtful, he thinks, if anybody will ever feel justified in resorting to it in cirrhotics; assuredly it could not be made use of in cases of wounds of the portal vein, for there would be no time to perform it.—*New York Medical Journal*, July 21, 1894.

#### THE ELECTRICAL TREATMENT OF UTERINE FIBROIDS AND SUBINVOLUTION.

As the result of a series of thirty cases treated by HAULTAIN (*Edinburgh Medical Journal*, August, 1894) within the last three years, on which he made accurate and careful observations, during and after treatment, he decides that:

1. The constant current is of the greatest value as a uterine hæmostatic when bleeding is due to small fibroids and subinvolutions.

2. It is curative in most cases of endometritis.

3. It reduces measurably the size of a certain proportion of fibroid tumors, while upon the majority it has a salutary, though less decided, action.

4. Its action on fibroids larger than a seven months' pregnancy is not curative, but temporarily palliative.

5. It reduces the size of subinvolved uteri.

6. Beneficial constitutional effects are usually noted.

7. Its method of hæmostatic action is both local and interpolar, the latter being probably the most potent.

#### TREATMENT OF ANAL TAGS.

In considering the treatment of this condition, the causes and possible results must be remembered. The superficial ulcer, although itself in many cases a source of slight discomfort, may afford an entrance to septic or tubercular material, and be the forerunner of serious trouble.

HORROCKS (*Quarterly Medical Journal*, July, 1894) states that the treatment of the superficial or callous ulcer is essentially the same. Rest for the ulcer must be obtained by thoroughly stretching the sphincter and dividing the fibres of the muscle which lie immediately beneath the bed of the ulcer. The granulating surface of the ulcer must be well scraped with a sharp spoon, and search made for any sinus running from its floor. Lastly, the projecting anal tag and loose folds of skin about the anus must be clipped away.

#### A MODIFICATION OF PIROGOFF'S AMPUTATION.

LE MOYNE (*Philadelphia Polyclinic*, August 4, 1894) calls attention to a modification of the above operation as employed by himself. Syme demonstrated the utility of forming a serviceable flap for ankle amputation by utilizing the dense, thick skin of the heel, already inured to pressure by natural use. Later, Pirogoff modified the operation of Syme by retaining the posterior portion of the calcaneum and incorporating it in the heel flap. In both Syme's amputation and Pirogoff's modification the lower extremities of tibia and fibula were removed. About fifteen years ago the author decided that an additional modification would be advantageous, this consisting in retaining the extremities of the tibia and fibula, and thereby avoiding considerable shortening, necessitated by the original method. In his first case the fragment of calcaneum was found too wide to enter the space between the malleoli, and entrance was gained by the removal of sufficient tissue from the inner aspect of each malleolus. The result was so good that he was very favorably impressed with the operation. Later he had an opportunity to put his modification into practical operation. The flap was formed according to the method advised by Pirogoff, except that the calcaneum was sawed less obliquely. The section of calcaneum being much wider

than the intermalleolar space, an excavation was made on each side, corresponding to its respective malleolus, and the parts accurately fitted to each other until coaptation was complete. Even with the admirable purchase afforded by that device, there was a tilting of the anterior border of the fragment, which was entirely overcome by the complete division of the tendo Achillis.

The stump was dressed with a long posterior splint and well padded forward at its inferior extremity. Primary union occurred, except at the location of one stitch, where there was slight suppuration. Five weeks from the date of the accident bony union was complete. The tissues of the stump seemed firm and healthy, and sustained the entire weight of the patient without discomfort or inconvenience.

#### GLYCERIN INJECTIONS AS AN OXYTOCIC.

PELZER (*British Medical Journal*) read a communication on this subject at a recent meeting of the Cologne Obstetrical Society. He had collected twenty-eight cases, including nineteen in his own experience. Glycerin was used eighteen times for induction of premature labor; in fifteen of these cases the pelvis was narrowed, in two there was Bright's disease, and in one placenta prævia. To stimulate uterine action at term, glycerin was injected in seven cases of simple atony, in two of placenta prævia, and in one for some other complication. The pains came on after an average interval of two hours following the injection. Eight to ten hours elapsed before complete dilatation of the os, or a longer space of time in cases of contracted pelvis. Two of the mothers died, both from severe eclampsia; the foetus was putrid in both cases. One child required craniotomy on account of its great size. Three children died from placenta prævia and strangulation by the funis; one, hardly twenty-two weeks old, died a quarter of an hour after birth. Only in one case could the violence of the pains be a possible cause of the death of the child. The glycerin had done its duty. Pelzer, however, deprecates injudicious zeal in the application of this method; an ounce to an ounce and a half, not three ounces, are sufficient for injection. The method is not suitable for cases of eclampsia and placenta prævia, except the lateral variety, where the placenta can be avoided.

GEUER (*ibid.*) read notes of three cases of induction of premature labor by injections of glycerin, in all of which both mother and child were saved. The first two mothers were

over thirty-two, with contracted pelvis; craniotomy had been performed in previous labors. The third case was an instance of bad eclampsia; 3x of glycerin were injected, the os being at the time uncontracted; there was oedema, with much albuminuria; forty hours later a healthy living child was born.—*Maryland Medical Journal*, August 4, 1894.

#### CHRONIC INFLAMMATION OF THE SEMINAL VESICLES.

Chronic inflammation of the seminal vesicles is not always easy to make out, as it has symptoms like inflammations of the urethra. ALLEN, in the *Medical News*, says that there may be a chronic urethral discharge, with shreds in the urine, or there may be vesical irritability with frequent micturition. In many cases there is some disturbance of the sexual function. In considering this subject the author offers the following suggestions:

1. The fluid in a distended vesicle, subjected to pressure, would escape at the point of least resistance, which would be the natural outlet, no matter how tortuous, unless the wall of the vesicle were ruptured by violence. Simple pressure on such a blind sac would seem better than an attempt to strip the vesicle down towards the duct.

2. The slow and unsatisfactory progress of a few cases may be due to the difficulty of emptying such portions of the vesicle which may in these cases be the chief seat of disease.

3. In some cases the ampulla of the vas deferens may alone be affected, when the stripping process would be easy and effective.

4. Disease of the vas deferens may possibly be of more importance than that of the vesicle itself, obstructing, as it does, the direct road from the testicle.

5. Simple massage of the vesicles may play an important part in the treatment.—*Maryland Medical Journal*, August 4, 1894.

#### TREATMENT FOR PAINFUL DEFECTION.

For painful defecation attending inflammatory pelvic conditions, DR. MURRAY (*Norsk Magasin* for Loegevid) recommends the following:

- R Bismuth subnitrate, gr. iiss;  
 Mercurial ointment, gr. iss;  
 Extract of belladonna, gr. iv to gr. v;  
 Cacao butter, q. s. for 1 suppository.  
 Sig.—2 suppositories a day.

The bismuth is added to prevent irritation of the mucous membrane of the rectum.—*Medical and Surgical Journal*, August 4, 1894.

#### VOMITING OF PREGNANCY.

A writer in the *Lancet* says, "I have not failed once for many years, by a single vesication over the fourth and fifth dorsal vertebræ, to put an end at once to the sickness of pregnancy for the whole remaining period of gestation, no matter at what stage I was consulted. The neuralgic toothache and pruritus pudendi of the puerperal condition yielded as readily, and to one application."—*Medical and Surgical Journal*, August 4, 1894.

#### IVY-POISONING.

A current number of the *Sanitarian* advises the application of Labarraque's (solution of chlorinated sodium) solution in this irritating affection. It should be applied in full strength by means of a pledget of lint or diaper cloth kept constantly wet with the liquid; it will afford relief immediately.

#### SEPTIC OSTEITIS IN CHILDHOOD.

A lecture on this subject was recently delivered by MR. EDMUND OWEN at the London Hospital for Sick Children, and is reported in the *Lancet* for May 26. Mr. Owen believes that a diagnosis of rheumatism is sometimes erroneously made, when the condition present is, in fact, osteitis due to some septic infection. This may occur without a history of local injury, but usually some illness has seriously disturbed the patient's nutrition. In such circumstances all the tissues of the body are rendered uncommonly susceptible to infection, and it is not strange that the delicate new bone at the end of the diaphysis should suffer. Any septic micro-organisms which have gained entrance into the body might readily implant themselves in this region of slight resistance. Here they would undergo prolific cultivation, secreting their ptomaines to poison the blood and disturb the nervous system. Two cases were presented illustrating this condition. In neither case could a satisfactory cause be discovered. Sometimes the disease is acute and fulminating, and carries the child off before a diagnosis has fairly been made. In others, as in the cases mentioned, it is slow, and simulates articular rheumatism in many respects. Unlike rheumatism, however, the heat, the swelling, the pain,

and the tenderness, although close to the articular area, do not involve it. The tenderness is limited to the region of the bone close below the junction cartilage, and at this point there is a definite thickening. In articular rheumatism the swelling, the fulness, and the redness are confined to the area of the synovial membrane, and there is no thickening about the bone; the results of treatment also aid in diagnosis. The relief of the symptoms of acute rheumatism is, as a rule, so prompt under the use of salicylic acid that an increase in the severity of the articular signs, or even a lack of any improvement after a few days, should arouse suspicion and call for a more thorough and careful investigation. The diagnosis should be made as promptly as possible, for error and delay lead to lamentable results. The treatment is essentially surgical. Incision should not be delayed until the presence of pus is demonstrated. Delay allows the septic inflammation to make irremediable havoc, so that the sooner the area of disease is attacked and cleared out the better. To wait for fluctuation is to give the staphylococci and other micro-organisms full opportunity to do their worst. The incision should be through the periosteum, and, if any pus is here confined, a free opening should be made. The diaphysis should be trephined to give free exit to all septic matter pent up within the bone.—*New York Medical Journal*, August 4, 1894.

#### SPLENECTOMY.

CONKLIN (*Medical Record*, July 28, 1894) reports a successful splenectomy. The patient, Mrs. A., American, aged twenty-nine, married, multipara, was admitted into St. Elizabeth Hospital, May 29, 1893. Her family record is without taint, menstruation normal, and general health but little impaired. Mrs. A.'s early life was passed in a highly malarious district in Southern Illinois, and up to her marriage and removal to Ohio she was subject to frequent attacks of chills and fever, and carried almost constantly an "ague cake" in her side. She had been free from malaria for several years, and, aside from an attack of typhoid fever, has had no serious acute illness. Two years before she began to have abdominal and pelvic pains, and some months later discovered a lump low in the abdomen. Examination disclosed a solid, freely movable tumor, sensitive to touch, in the left iliac region, dipping into the pelvis, but not connected with the uterus, and a small cyst of the right ovary. The uterus was normal in size, but retroverted.

Dr. Jewitt made a *cœliotomy* June 10, 1893. The solid tumor proved to be a displaced spleen about twice the normal size. It was free from adhesions and easily replaced. The right ovary, containing a cyst the size of a small orange, was removed; left ovary normal; convalescence was uneventful. She was soon discharged, with positive instructions to wear constantly a properly fitting abdominal supporter, with the hope of retaining the spleen in position.

Mrs. A. was readmitted into the hospital during the author's service, September 23, 1893. Shortly after her return home she again began to suffer from pelvic symptoms, and for the past two months had nearly continuous abdominal soreness and several severe paroxysms of pain, which drove her to bed. Her abdomen had been steadily enlarging.

Six days ago, while doing the family washing, she was seized with agonizing pain in the abdomen, which required for its control the administration of morphine. Vomiting of large quantities of bile-colored fluid began on the following morning, and still recurred. In spite of treatment, the bowels refused to move for more than a week; temperature normal.

On examination, the abdomen was found tympanitic, very sensitive to pressure, and occupied by an immovable, solid tumor, which completely filled the left side from the pelvis to the ribs and extended considerably beyond the middle line; it could easily be touched per vaginam.

The former operation greatly simplified the diagnosis, and left no doubt that the tumor was the enlarged and inflamed spleen. The acute symptoms were attributed to intestinal obstruction, due either to pressure from the spleen or to adhesions at the seat of the ovarian stump. The symptoms grew steadily worse until forty-eight hours after admission, when the bowels responded freely to treatment, after which the vomiting ceased and her general condition improved. The respite was of short duration. The local tenderness, paroxysmal pains, and vomiting returned, accompanied by fever. The temperature ranged from 99° to 101° F. for ten days, and measured 100° F. on the morning of the operation. Peritonitis had evidently supervened, and at a consultation of the hospital staff it was decided that the removal of the offending spleen offered the only chance of recovery.

The operation was performed October 7. The parietal incision, seven and a half inches in length, was made along the outer border of the left rectus. On exploring the spleen, contrary to expectations based on the revelations

of the previous operation, it was found adherent to the abdominal wall, omentum, and intestines. The intestinal adhesions especially were firm and extensive, involving the entire under and inner surfaces of the tumor. Their separation consumed much time, the capsule of the spleen being torn in several places. The peritoneum gave unmistakable evidences of active inflammation. The pedicle was long, twisted through three complete turns, and, with its engorged and tortuous vessels, resembled a huge umbilical cord. It was trans-fixed, firmly tied with heavy twisted silk, using the Staffordshire knot, and for greater security encircled with another turn of the ligature. The ligature was cut short and the pedicle dropped, a glass drainage-tube placed, and the wound, on account of the patient's condition, hastily closed.

The hemorrhage was slight and easily controlled. The shock was profound and wholly out of proportion to the blood lost or the length of the operation. Hypodermic injections of brandy and strychnine were freely used. Apart from the shock, which threatened to prove fatal for hours after removal to bed, and the temperature, which for twelve days measured from 99° to 101° F., precisely as it had before the operation, there was nothing worthy of special comment during convalescence. At no time was there swelling of the parotid or lymphatic glands. The spleen, drained of its blood, weighed four and a quarter pounds and measured ten inches in length by five and a half in breadth. It was firmer in texture and darker in color than the normal gland. Microscopical examination showed thickening of the trabecular and intercellular connective tissue and pigment in the vessel walls. By an oversight, no microscopical examination of the patient's blood was made before or soon after the operation; at present the proportion of the red and white corpuscles is normal. Seven months after the extirpation, Mrs. A. has grown very fleshy, and reports excellent health, save an overpowering drowsiness.

After a summarizing of the literature on the subject, Zenner concludes that the present position of splenectomy may be briefly epitomized as follows: It is unjustifiable in leucocythæmia or other conditions in which there is extensive involvement of the lymphatic glands or a notable increase in the white blood-corpuscles.

It is indicated in tumors, simple hypertrophies, and other splenic enlargements which have proved rebellious to simple measures and are attended with danger or serious disability. In movable or displaced spleens requiring

interference, extirpation is preferable to operative fixation.

Severe traumatism of the spleen, with or without an external wound, or simple prolapse of the gland into a parietal wound, demand, as a rule, immediate extirpation. In cases of protrusion, experience shows that excision, partial or total, is a safer procedure than mere replacement.

Removal of the spleen for cystic disease has an excellent record, but most authors advise a preliminary trial of incision with drainage. In abscess it is better, except in rare cases, to incise and drain than to attempt removal of the organ.

#### OSTEOPLASTIC RESECTION OF THE SACRUM.

It is now generally admitted that the only way of dealing effectively with certain ailments of the rectum, especially in its upper parts, is by approaching the seat of disease from the posterior wall of the pelvis. KAMMERER (*Medical Record*, July 28, 1894), with this sentence, begins an able article recording in detail six operations performed by himself, with satisfactory results. He advocates Rydygier's procedure, which is as follows: The soft parts are incised, beginning at the posterior superior spine of the ilium on the left side and running down to the tip of the coccyx, thence in the median line to the anus. After division of the sacro-sciatic ligaments, the soft parts are removed from the anterior surface of the sacrum by the hand of the operator. A transverse incision is then added below the third sacral foramen, and the bone divided along this line with a chisel. A flap is now turned to the right side. With a retractor inserted at the tip of the flap, the latter can be easily held aside and manipulations about the rectum can be as readily carried on as when the bone has been entirely removed. The author has been impressed in all his cases with the rapidity with which this preliminary operation can be done and the absence of profuse hemorrhage. He fully endorses Rydygier's claim that his osteoplastic resection is a much less bloody operation than the permanent removal of coccyx and sacrum by any one of the other methods, with dissection of the soft parts from the posterior surface of the sacrum. In only one instance did Kammerer meet with considerable hemorrhage; here he operated in the lateral position. The knee-elbow position was employed in all the other cases, with distinct elevation of the pelvis, especially of the sacral region, the writer declaring this to be the most

desirable one for rectal surgery, since it controls hemorrhage through elevation, gives excellent access to the field of operation, the surgeon standing between the slightly separated thighs of the patient, also facilitating manipulations with the chisel, the pelvis being supported by sand-bags placed under the anterior iliac spines.

When the flap, including the coccyx, part of the sacrum, and the integuments, can be, from the nature of the case, returned to its place and sutured, the result will be an ideal one as regards restitution of the normal contour of the sacral region. In suturing the transverse incision the author always passes the needle down to the bone, but never includes the bone itself in a suture by any device whatever. Notwithstanding, in several cases in which he has had to elevate the flap a second time, he has always found firm union of bone surfaces, either fibrous or partly osseous. It is unfortunate that secondary operations so frequently become necessary in rectal surgery, for even when we have resected the rectum and made a circular suture of the ends, we frequently find that the latter gives way on the posterior circumference of the bowel. The operation of raising the flap a second time is no more tedious than the first. Greater care must be exercised to avoid the rectum, which now has been drawn close to the anterior surface of the sacrum by cicatricial contraction. When we are dealing with cases, such as fistula, where tamponade of the wound-cavity becomes necessary for some time, we should not suture the flap, but leave the wound-cavity entirely open. The author had good proof of the advisability of this procedure from his fourth case, where he got very good union of the transverse and vertical incisions, but in which a successful tamponade of the deep wound-cavity (about six inches) was not easily effected through the small opening corresponding to the unsutured part of the original incision. To this fact he attributes the ultimate re-establishing of a small vaginal fistula. Such wounds ought to heal from the bottom of the wound-cavity, to avoid even the slightest retention endangering the object in view, and the best guarantee for this is a wide opening, allowing free inspection and tamponade.

Where no sutures are used, some retraction of the flap develops after a time. There is no doubt much less than in flaps that are without a bony substratum. Even when only the lateral incision to the left of the sacrum has remained open, a distinct elevation of the soft parts over the sacrum results from the same cause,—a deformity which can, no doubt, at the proper time, be very readily remedied by an insignifi-

cant plastic operation. This is not so readily accomplished when no suturing at all has been done.

After some time secondary operations on the rectum are even more difficult than the original ones, owing to the development of much cicatricial tissue about the gut, which makes the latter more rigid, and does not, in consequence, permit the approximation of such parts which we may desire to unite by sutures. From all this we may conclude that it will be wise to do secondary operations as soon as the condition of the patient will permit.

The cases of fistula reported have not been entirely cured. They have been much benefited, and one of them is very likely closing. An anterior laparotomy would certainly have been unwise in any of them.

While technically difficult, the sacral route is still the easiest way to get at the seat of disease when the rectum is affected, and also in some cases in which the uterus is to be dealt with. Rydygier's preliminary operation is certainly well devised, and being as simple as the permanent resection of the sacrum, while not disfiguring, assuredly deserves preference.

#### HYPERSECRETION OF THE SWEAT-GLANDS OF THE FEET.

Against sweating feet, LEGOUX (*Therapeutische Blätter*, Wien, July, 1894) recommends,—

R. Liquor ferri sesquichlor., 30;  
Glycerini, 10;  
Ol. bergamot, 20. M.

Sig.—Apply with a brush each morning.

#### DANGERS OF GLYCERIN INJECTIONS INTO THE UTERUS FOR THE PURPOSE OF INDUCING PREMATURE LABOR.

EMBDEN (*Medical Record*, July 28, 1894) gives an extract of Pfannenstiël's article concerning the dangers connected with intra-uterine injections of glycerin for the purpose of inducing premature labor, and reports the history of two cases treated by the same writer, as well as one of his own. As a result of the above studies, he concludes that Pelzer's method is liable to occasion indisputable symptoms of glycerin-poisoning. This will be a death-blow to the method.

Concerning the first case, the glycerin cannot be considered the cause of the woman's death, as she suffered from nephritis. It is, nevertheless, remarkable that there was found a small

quantity of blood-colored water in the bladder, the urine being entirely free from blood in the last days before the injection was performed, as shown by frequent examinations. Pfannenstiël tries to find the cause of this in the injected glycerin.

The second case was undoubtedly a case of glycerin-poisoning, and although it did not damage the future health of the woman, it kept her in danger for some time. The woman was in perfect health up to the time of the injection; the urine was normal. One hour afterwards she had symptoms of glycerin-poisoning.

In the author's case there was a woman with nephritis, but there was not noticed at any time before the injection any trace of blood in the urine. After the delivery there was a good quantity of a dark-red urine in the bladder. In examining the same, Embden failed to find any red blood-corpuscles, but there was a large amount of hæmoglobin. The explanation of this appears to be a decomposition of the blood, brought on by the injected glycerin.

This does not seem so very strange, as we know—according to Pfannenstiël—that glycerin is liable to occasion a decomposition of the blood, as has been shown by numerous experimenters with dogs and rabbits, the hæmoglobinuria caused by glycerin bringing on a glomerulo-nephritis, followed, after the injection of more glycerin, by interstitial nephritis as well as by interstitial hepatitis.

It is, of course, strange that neither Pelzer nor others met with a similar accident after injections of glycerin.

Pfannenstiël finds an explanation of this in the fact that Schwan, Lebedeff, and Filehne have shown that in rabbits, when the glycerin is brought under the skin, hæmoglobinuria always occurred, but that it did not occur, or in a slight degree only, when it was injected directly into the veins. Without giving an explanation of this, Pfannenstiël deems it possible that, in Pelzer's cases, the glycerin was very rapidly absorbed by the circulatory system, while in his cases it acted in the decidua uteri as if it had been injected by the hypodermic method.

The writer's case is particularly interesting from the fact of the icterus following the hæmoglobinuria. It seems indisputable that this was caused by the decomposition of the blood poisoned by glycerin. The writer rather leans to the belief that the semi-comatose condition which appeared in his patient was brought on by the same cause; it did not look like a uræmic coma. Another danger of the injec-

tion of concentrated glycerin is the possibility of a thrombosis. Another objection to this method, in common with all injections of fluid of any kind between the uterus and the foetal sac, is the possibility of air entering the circulatory system.

Finally, the writer asserts that Pelzer's method should not be used at all for the purpose of inducing premature labor; more especially is it to be avoided in cases of nephritis.

#### FISTULA OF THE STOMACH IN A CHILD.

A child aged six years swallowed by mistake some hydrochloric acid, following which developed an oesophageal stricture, and gastrotomy was performed. Later gradual dilatation of the oesophagus was practised, and eventually food was introduced by means of a catheter passed through the mouth. At the time he was brought to the service of Dr. CHORON (*La Presse Médicale*, July, 1894) the patient was suffering from marasmus and emaciation threatening his life, and closure of the artificial opening was attempted to stop the continuous outflow of gastric juice and mucus, which was causing an eczematous condition of his entire abdomen.

The stomach was irrigated with a three-per-cent. solution of boric acid. The opening was excised, with a small collar of skin around it. The opening in the abdominal wall was now enlarged towards the left costal border.

With curved scissors the stomach was separated from the abdominal wall. A wound of the liver was tamponed to arrest hemorrhage.

The stomach was sutured with catgut, the other structures with silk (No. 1); first a Lembert suture to the serous membrane, then the muscles and skin received each a separate suture.

#### TREATMENT OF CHRONIC GONORRHEA.

Before the Society of Internal Medicine at Berlin, ROBERT KUTNER (*La Presse Médicale*, July, 1894) demonstrated the advantages of graduated instillations, basing his reasons upon two observations: 1, that gonorrhoea in the chronic form shows itself in circumscribed places; 2, that the introduction of the olive-tipped sound produces more pain at these localities than at other points in the canal.

First, with a *bougie à boule*, he measures the distance of these sensitive spots from the meatus. He then introduces a syringe with a hollow sound adjusted to the point, and applies silver nitrate (one per cent., ten per cent., or twenty

per cent.) or copper sulphate to the spots previously located by his measurements.

The advantages of this method are,—

1. Exact location.
2. Energetic action of the medicine exactly placed.
3. Less reaction.
4. Economy of time.
5. Simplicity of the procedure.

#### TREATMENT FOR ACNE VULGARIS.

PHILIPPSON, in *Therapeutische Monatshefte*, November, 1893 (*Monat. Praktische Dermat.*, July, 1894), says that the causation of acne is still so uncertain that the treatment must be symptomatic.

The pustules are opened and the contents pressed out; then he cuts through the induration; over this a fifty-per-cent. salicylic plaster is laid. Compresses of lead-water and acetic acid soften the skin, cause the pustules to disappear, and relieve the irritation.

For the milder forms, soap, salicylic acid, naphthol, resorcin, and sulphur are recommended.

The following formulæ are used at Lössor's clinic in Berlin:

1. R Naphthol, 10 parts;  
Vaseline,  
Saponis viridis, of each, 20 parts;  
Sulphur præcipitatis, 50 parts.  
M. et fiat pasta.
2. R Camphor trit.,  
Vaseline, of each, 10 parts;  
Pulv. cretæ albæ, 5 parts;  
Saponis viridis, 15 parts;  
Sulphur præcip., 50 parts.  
M. et fiat pasta.
3. R Resorcin,  
Amyli puri, of each, 5 parts;  
Vaseline, 15 parts;  
Zinci oxidi, 5 parts.  
M. et fiat pasta.

These pastes can be applied until inflammation follows, or can be washed off in a quarter to a half-hour, and can be followed by powders.

The first two are best used in the latter manner, while the third is milder. For the mildest forms, where single pustules are found, the following wash is used:

- R Acid. acet. conc.,  
Tinct. benzoes,  
Spirit. camphor., of each, 6 parts;  
Spirit., q. s. ad 100 parts. M.

Sig.—Apply with sponge night and morning.

*PELVIC EXUDATE.*

In a series of papers with the above title, PROFESSOR BIRNBAUM closes with the following therapy (*Der Frauenarzt*, July 7, 1894):

The best prophylaxis is a thorough antiseptic handling of each childbirth, each operation, or other manipulation of the genitalia.

The special treatment is necessarily local, since the fever and constitutional symptoms are dependent upon the local process.

Of prime importance is the removal of irritation or anything causing congestive changes or which obstructs the backward flow of blood, and avoiding unnecessary movements or internal examinations.

So long as fever and pain denote continuance of inflammation, cold compresses, ice-bags, or water of moderate temperature are employed to counteract it.

Kisch recommends for the acute stage intra-vaginal applications of cold by means of a special irrigator.

For plethoric patients bloodletting is recommended early in the childbirth by applying from six to ten leeches in the inguinal region of the affected side.

Not so strongly recommended is the use of leeches to the vaginal wall, owing to the irritation and the danger of infection.

The ice-bag is used only so long as the pain continues; then water compresses (22° to 25° C.) are resorted to, which may be continued for hours, under which treatment the absorption often goes on to completion.

The much-lauded use of unguent. cinereum, or ointment of potassium iodide, has yielded less prompt results than the water applications.

Where foul-smelling lochia are present, the vagina is washed out many times a day with sublimate (one-tenth per cent.) or carbolic-acid solutions (one to two per cent.).

For the fever, when it is very high and persistent, large doses of cinchona, antipyrin (cautiously), sodium salicylate, digitalis with acid, and the like drugs are employed.

If, in spite of this, the exudate goes to pus-formation, it is still possible to have absorption by the use of compresses. But when the continued high fever denotes the presence of pus, then drainage of the collection is required.

When there is a tendency to point externally, applications of flaxseed poultices, etc., are made.

When fluctuation is detected, an incision is made above Poupart's ligament, from one to two centimetres and two to three centimetres from the anterior superior iliac spine.

When fluctuation is not positive, exploratory puncture is recommended.

From the rectal region it is more difficult to remove the collection, but exploratory puncture may also be tried through the vagina. After opening in this situation, it is well to employ drainage.

When the abscess breaks into the rectum or bladder, without sufficient drainage, Byford recommends inserting a sound through the abscess opening, turning the point against the vaginal wall and cutting against the point of the sound.

If the exudate does not go on to pustulation, then iodine, internally as well as externally, is employed.

Painting with tincture iodi, inunctions of iodine, and potassium iodide ointment, or the rubbing of potassium iodide and lanolin into the abdominal wall.

Painting the cervix and vaginal mucous membranes with the tincture of iodine, or with iodine and glycerin, followed by dusting with iodoform, is also advised.

In anæmic patients the use of iodine must be guarded.

After iodine, cold, lukewarm, or hot irrigations, with or without addition of medications, are recommended.

The use of massage is recommended with caution, suppuration contraindicating this.

Electricity has not proved a success.

Mercury as inunction and internally is used where gonorrhœal cause is suspected.

Naturally, in each case good diet, iron, quinine, wine, and similar tonics must be used, and the patient must not be allowed to leave her bed too early.

*THE VAGINAL ANUS AND ITS TREATMENT.*

BUCKMASTER (*New York Medical Journal*, August 11, 1894) gives a carefully condensed report of the literature throwing light on this much vexed subject, with a detailed description of the methods he has employed in overcoming the deformity.

There are so few cured cases that it is easy to explain the attitude of conservative men towards operative procedure. It is important to classify the cases, that we may determine which are fit for operation. It is convenient to divide the cases into two classes. The first class comprises those patients who have control, and the second class includes those patients who pass their fæces involuntarily. The first class is not large in number, and if the patient will take

precautions to preserve cleanliness, and if the opening is large enough to pass formed fæces, operation is not advisable. A douche after each movement will in some cases prove sufficient to keep the patient comfortable. If such precautions are neglected, the mucous membrane of the vagina will become excoriated and abscesses may form in the connective tissue. If, in spite of this advice, the patient should still desire an operation, the results are sufficiently good and the dangers under sufficient control to warrant compliance with her request.

The second class, or those who have no control, includes the great number of cases. Most of them are recognized shortly after birth, and unless the opening is so small that it obstructs the passage of fæces, nothing need be done until a later time. Fæcal matter in healthy young infants is quite unirritating, but as the character of their food changes it may cause great trouble; for this reason careful attention should be given to the diet. It is easier to mould the tissues after the child is fifteen years of age than before this time, but it is not necessary to wait on this account.

In considering the dangers of the operation, we must not forget that all of the fatal cases occurred in a day before antiseptic surgery was understood. The operation the author describes is not more dangerous, he states, than that used to restore a ruptured sphincter. It is used particularly in those cases where there is no control. In cases where the patient has control, and it is necessary to free the bowel for some distance, there is more risk. A number of deaths have been recorded, but with the better technique of to-day the risk is no longer great if the patient be healthy.

The first step in the operation is to introduce a probe into the fistula from the vagina, and bring out the point of this instrument just above the levator ani muscle, the tissue above the probe being divided. The skin should be pierced in front of the lower part of the sling formed by the fibres of the levator ani muscle. The location of this muscle should be ascertained, if possible, before the patient is etherized. When the tissues above the probe have been divided, the rectum is seen, is divided, and may be slightly freed by a few strokes of the knife. It must be remembered that the backward extent of the incision only indicates the backward limit for the plane in which it is found; the skin is divided about an inch farther back.

The next step is to draw the rectum to the skin, and here one is very apt to make a mistake.

The rectum should be fastened to the skin without strain. If proper ligature material be used, and the strain is not too great, the sutures will never cut out, but will become embedded in the tissue, as is the case in all plastic work. On the second day after the writer first operated, he found that the strain had been too much for his stitches, and was obliged to cut those at the sides and place a new one in the middle of the wound; this entirely removed undue tension. If the tension had been too great, he would have drawn the rectum down as far as possible without strain, trusting to a future operation to reach the skin. By careful attention to this caution we can never fail to gain something, and it is only a question of time when the rectum can be securely anchored to the skin. It is important to bear in mind that if union of the rectum to any point of the skin is secured, no matter to how slight an extent, it is not a difficult matter to bring the remainder of the circumference of the bowels in the desired position at a later period.

Having united the rectum to the skin, the raw surfaces left at the side are sewed together. After the completion of the first step, the rectum opens below the vagina, and no raw surfaces are left. The patient can be on her feet in ten days.

The second step of the operation consists in forming that part of the pelvic floor which is usually known as the perineal body. It will differ very much in different cases, as the distance between the abnormal opening and the urethra varies. It cannot be properly done except by an operator who is a good plastic surgeon.

The third step suggests itself on theoretical grounds; the author has not yet had opportunity to put it into practice. He means to split the fibres of the levator ani muscle, as has been done with the rectus muscle in gastrotomy. If this is practicable, we ought to obtain a fairly good sphincter. It is not unlikely that those cases which have gained control after operation have done so by having the muscle, which has been divided, grow about the rectum.

#### FIXATION IN THE TREATMENT OF FRACTURES INTO JOINTS.

In an interesting discussion of this subject by COOK (*International Journal of Surgery*, August, 1894) the following conclusions and rules of treatment are laid down:

1. That bony or serious fibrous ankylosis is the result of injury and subsequent inflammation and not of immobilization.

2. That early passive motion only disarranges the fragments of bone, thereby increasing the production of callus; that it irritates the injured ligaments and, by increasing the inflammation, tends to produce the ankylosis it is thought to prevent.

3. Immobilization is useful only when active inflammation is present, or until the ruptured ligaments and broken bones have thoroughly united.

4. The logical treatment of a fracture into a joint, therefore, should be rest and local applications to reduce inflammation. Reduction of the fracture as early as possible, then immobilization until the bones and ligaments have united (from three to eight weeks, or more, according to circumstances).

5. Passive motion, massage, and use till the tissues become normal, or, if the massage fails, complete rupture of all adhesions under an anæsthetic. The factors which will ultimately determine ankylosis are the nature of the original injury, the character and duration of the subsequent inflammation, the destruction of bone and cartilage, cicatricial contraction of the soft tissues around the joint, and the age and condition of the patient.

#### DANGERS OF THE LONG RECTAL TUBE.

It has long been a disputed question as to whether the long rectal tube can safely be passed into the sigmoid flexure. In this relation the opinion of MR. HARRISON CRIPPS in a recent number of the *British Medical Journal*, is of interest.

In spite of the condemnation of the long rectal tube by Brodie, Treves, and many other eminent authorities, he still finds that in most cases of obstruction or supposed obstruction the tube has been introduced. Fortunately, these tubes are fairly soft, so that in a capacious rectum, when they impinge and are arrested about opposite the promontory of the sacrum, they simply coil up and do no harm. If stiffer ones are used, the patient's life is placed in imminent risk. A patient at St. Bartholomew's Hospital was to be operated on for ruptured perineum. In order to increase the supposed efficacy of the injection, a quart of soap and water, with some ounces of oil, were injected by means of a long tube; the injection never returned. A few hours afterwards, owing to the acute symptoms, Mr. Cripps assisted one of his colleagues in opening the abdomen. The soap and water and oil were found in the abdominal cavity, and a hole below a reduplicated fold in the upper part of the rectum.

The patient died. He says that the idea that these tubes can be generally passed into and beyond the sigmoid flexure is a pure delusion, save in the rarest circumstances. As a means of diagnosis, or of treatment of stricture beyond the reach of the finger, tubes of any kind are absolutely useless. If a stricture is actually present, it would be 100 to 1 against the long tube or bougie entering it, for it would almost certainly catch in the cul-de-sac generally caused by the invagination of the stricture. If a stricture is not present, the arrest of the bougie by the sacral promontory leads to delusive diagnosis. Brodie, in his lecture, alludes to a case in which a worthy practitioner had spent over one hundred and fifty hours in dilating a supposed stricture situated high up. The treatment had extended over a period of a year. Brodie, who was present at the post-mortem examination, found that there was no sign of a stricture, the bougie becoming arrested by a curve of the sacrum.—*Boston Medical and Surgical Journal*, September 13, 1894.

#### THE TECHNIQUE OF CURETTAGE.

M. SÄNGER (*International Journal of Surgery*, September, 1894) states that, aside from the infectious, gonorrhœal forms of chronic endometritis, the most frequent and important varieties are endometritis, menorrhagica, and hypersecretoria. For the former (endometritis interstitialis, fungosa, climacterica) the best treatment consists in curetting, followed after a few days by the application of caustics. In endometritis hypersecretoria, which is usually limited to the cervix uteri, irrigation, gauze "drainage," and cauterization are especially indicated. Irrigation must be preceded by dilatation of the cervix with laminaria tents, and rarely effects a cure unless associated with other measures. As a preparatory procedure to cauterization, washing out the uterus with a soda solution is of service. The use of gauze tampons, especially of medicated gauze, has a favorable action, although they should not be regarded as promoting drainage. They have the disadvantage of requiring to be frequently renewed. This objection does not apply to cauterization; the stronger the caustic the less frequently it has to be repeated. Säger believes that in general the cauterization resorted to is too mild and too frequently repeated. Among caustics he prefers a fifty-per-cent. solution of chloride of zinc, which is suitable for catarrhal as well as chronic, infectious, and menorrhagic forms. In cases where the cervical canal is narrow, however, in virgins and

nullipara, weaker solutions are in place. If a fifty-per-cent. solution be employed, the application should not be repeated until the end of sixteen to twenty days. For cauterization, Sanger employs a long, thin, silver sound.

#### DIAGNOSIS AND TREATMENT OF PROSTATIC ENLARGEMENT.

BELFIELD (*Indian Medical Journal*, August, 1894), in the following sentences, expresses his views on this subject :

While the etiology of prostatic enlargement still remains a matter of speculation, it is certain that the earliest clinical symptoms are due to vascular engorgement of the prostate and, by consequence, of the bladder. The actual increase in the size of the gland should not obscure the other factors in producing the symptoms, which may be out of all proportion to the perceptible enlargement. The factors contributing to the familiar symptoms associated with prostatic enlargement are :

1. Venous congestion and edema of prostate and bladder.
2. Fibroid thickening of the vesical (prostatic) sphincter, often extending to the detrusor and to the prostate.
3. Suppuration in the prostatic urethra (glands and utricle).
4. Hypertrophy of the prostatic elements (glandular or muscular, or both).
5. Chronic retention of urine, due to any one or all of these four antecedent conditions.

The most important as well as the most difficult task in diagnosis is the differentiation among these various morbid states ; for the prognosis as well as the treatment is determined by the predominance of one or another of them. For example, a prostatic patient complains of frequent and painful urination ; the chief trouble may be an aggravation of the usual venous congestion, in which case a brisk laxative, suppositories of ichthyol, and ergotin and strychnine internally will secure speedy relief. Again, the symptoms may be due to prostatic suppuration, in which event irrigation of the deep urethra with hot water containing hydrastin or silver nitrate is needed ; or the frequent urination may be simply the overflow of a distended bladder, which is relieved by the cautious daily use of a clean catheter.

It should be remembered that the symptoms clinically associated with prostatic hypertrophy depend upon several distinct morbid conditions, of which the mechanical impediment to the exit of urine may be the least ; and that no

routine treatment can be prescribed, the requirements varying with the case.

Our resources for meeting the needs of different patients may be thus summarized :

1. *Medical*.—(a) Improvement in the blood circulation through prostate and bladder is favored by proper diet and exercise, avoidance of constipation, massage of prostate between a sound in the bladder and finger in rectum, and by the daily use of a clean catheter ; internally, ergotin and strychnine are certainly useful.

(b) Suppuration in the bladder neck requires irrigation of the prostatic urethra with hot water, solutions of hydrastin, silver nitrate, etc., in addition to the measures already mentioned.

(c) Induration and distortion of the bladder neck may be improved by dilatation with large sounds or a special dilator.

In a certain percentage of cases the time arrives, sooner or later, when these measures fail to relieve, and more efficient and immediate aid must be rendered.

2. *Surgical Methods*.—(a) The simplest is puncture of the membranous urethra from the perineum and introduction of a drain, which is permitted to remain for a couple of weeks. The subsidence of congestion and edema, and the cleansing of the bladder thus induced, sometimes makes an apparent cure for many months. Puncture with a trocar through the prostate (Harrison), or drainage of the bas-fond behind the organ, is even more desirable.

(b) By a perineal urethrotomy the surgeon can secure not merely drainage, but also thorough digital stretching of the prostate and the incision or excision of obstructions at the orifice of the bladder.

(c) More satisfactory excision of prostatic obstructions has been accomplished by a combination of suprapubic cystotomy with perineal urethrotomy,—now a standard operation.

Within the past year there have been reported attempts to relieve the sufferings of the prostatic by securing atrophy of the enlarged prostate ; by Bier, through ligation of the internal iliacs, and by Raum,\* through castration. Bier reports three cases ; in one, death from septic peritonitis occurred ; in the remaining two, marked reduction in the size of the gland and decided improvement in symptoms

\* The credit of proposing castration as a means of producing prostatic atrophy undoubtedly belongs to Dr. J. William White, though Raum was probably the first to make a practical application of the proposal on man.—ED.

are reported. Castration alone is said to have accomplished a cure in Raum's two cases.

Two new operations upon the enlarged prostate itself have been recorded; one by Nicoll, who made a submucous removal of the entire prostate from the perineum in two cases with good result; the other, by Belfield, combines the removal of any part or all of the prostate with perfect drainage of the bladder and deep urethra. By incision into the ischio-rectal fossa, the prostate and trigone are laid bare and incised in the median line; each half of the prostate can be enucleated to any desired extent. A suprapubic incision—robbed of its danger by the perfect drainage secured through the posterior wound—can be made, if required for freedom of manipulation. This operation seems to meet all the indications of all cases. Like most other operative procedures, it is undoubtedly too severe for feeble patients to endure.

#### ABSCESS OF THE APPENDIX.

During a recent clinic MCBURNEY (*International Journal of Surgery*, September, 1894) presented a case of more than usual interest and one rarely met with. Three weeks prior to admission the patient had been in good health, when she was seized with a pain in the right iliac fossa, together with nausea and vomiting. The pain continued to increase in severity up to the time she entered the hospital, ten days before. She had a temperature of  $101^{\circ}$  F., pulse rather feeble, abdomen slightly tender on pressure, but with the walls relaxed. On palpation, a tumor in the right iliac fossa could be readily felt, which was not adherent to its walls, nearly spherical in shape and nodular in character. The history of the case was not of much aid in arriving at a diagnosis. There was no reason to believe that the tubes and ovaries were affected, and although the tumor was situated very near the pelvis, it did not extend into that cavity. There was no distention or obstruction, such as would be caused by a tumor in or around the intestine, thus pointing to the origin of the tumor as an abscess of the appendix.

As the patient was not suffering from high fever, nausea, or distention, the trouble being entirely localized, operation was postponed. The next day the tumor had entirely disappeared, and, unfortunately, no attention had been paid to the character of stools, which might have afforded an explanation of this occurrence. There is no doubt that she had an abscess of the appendix, which evacuated itself into the intestine through a new passage. The

patient was in a more comfortable condition and the pain entirely allayed. Close examination of the abdomen revealed an induration of the tissues at the site of the original tumor. The patient continued to have fever, though somewhat reduced in intensity since that time. Her condition remained about the same. Slight abdominal tenderness, but no distention, was present, and the bowels were active. In cases of this kind, where the abscess has burst into the intestine, some patients have continued in good health and been entirely cured. On the other hand, cases with this history sometimes suffer from repeated recurrences, until an operation has been done for their final cure. In such cases, on cutting down, the reporter has found the appendix entirely separated and lying quite loose in the mass of connective tissue forming the wall of the abscess, the opening in the gut still existing.

Therefore, McBurney advised operation in the above case. He calls attention to the fact that cases of appendicitis differ very greatly in character. Incisions made through the abdominal wall must be adapted to the requirements of each case. In some cases the appendix can be removed with perfect ease through a very small incision, say one and a half inches in length, but to apply such a method, as recently described in some of the journals, indiscriminately to the different cases, and to adopt a standard incision for abdominal section, is useless. The incision must be adapted to the character of the case to be operated on; we should not accept any method of entering the peritoneal cavity through a small opening in operating for an extensive disease. If we know by experience that the disease is small in extent, then we can remove the appendix through a small aperture with advantage. This, of course, does not apply to the cutaneous incision.

The operator, after cutting down to the appendix, found an abscess cavity. The appendix was removed and the opening in the intestine sewed up. The patient was in such a condition that the removal of the diseased appendix seemed the only course to prevent an imminent attack of appendicitis.

#### CÆLIOTOMY IN TYPHOID PERFORATION.

A case of operation of this nature is reported in the *British Medical Journal*, No. 1783. The patient was in the fourth week of the typhoid fever. Symptoms of perforation developed, attended by collapse. The abdomen was opened as soon as the patient reacted. Perforation was

discovered twelve inches above the ileo-cæcal valve. The ulcer, which had for its centre this perforation, was excised; the opening in the gut was closed by mucous membrane and peritoneal sutures; the operation lasted an hour; the patient lived until the sixth day.

*REPORT OF THREE CASES IN WHICH  
THE MURPHY BUTTON WAS  
EMPLOYED.*

RUTH (*Mathews's Medical Quarterly*, vol. i., No. 4) reports three cases in which the Murphy button was employed.

A child of five years had suffered from intestinal obstruction for three months. This was due to sarcoma, so extensive that the entire cæcum, two inches of the colon, three-quarters of an inch of the ileum and the appendix had to be removed. The continuity of the gut was restored by a Murphy button. The child lived more than six months, and died of recurrence.

The second patient was thirteen years old. A portion of the ileum was resected because of obstruction due to tumor of the mesentery. End-to-end approximation was made with a large size Murphy button; this was passed on the fourteenth day.

The third case, twenty-eight years old, was suffering from a fistulous opening into the jejunum. Five inches of gut, including the fistula, were resected and the continuity restored by the button. As when the abdomen was nearly closed it was noticed that fæcal gas was passing, the wound was reopened to ascertain its source, and five inches more of injured gut removed, containing a pus cavity near the mesentery. Another junction was made as before, but the opening through which the gas passed was not found. This case perished in three hours.

Ruth claims for the button that it shortens the time required to do an intestinal anastomosis fifteen to forty minutes; that, if properly applied, leakage is impossible, and no hydraulic or gaseous pressure is needed to determine the fact. It is the strongest junction known. It gives the minimum cicatrix and contraction, and is the only plan that can be relied upon to make the ideal junction. After completing its work it leaves no foreign body of any kind behind. There is no danger of causing obstruction by failure of the button to pass the ileo-cæcal valve. The greatly lessened mortality makes this hitherto most dreaded field of work compare favorably with other intraperitoneal operations. It should relegate fæcal fistulæ following operations for strangulated hernia and

intestinal resections to the past. No care need be taken to have the proximal and distal portion of the gut correspond in size.

*TREATMENT OF VESICO-VAGINAL FIS-  
TULA BY OPERATION FROM  
WITHIN THE BLADDER.*

In an instructive paper in the *Annals of Surgery* for October, 1894, BOND advocates the treatment of vesico-vaginal fistula by operation from within the bladder.

The cases most suitable for treatment by the new route are those in which extensive cicatricial contraction has occurred; in such cases the vaginal roof is often tightly stretched across the pelvis, and the neck of the uterus cannot be drawn down; if, under these conditions, the fistula be extensive and situated high up near the uterus, considerable advantage is obtained by choosing the new method.

As regards the operation itself. The bladder may first be injected, the finger of an assistant meanwhile blocking the fistulous opening; if this be impossible, it may be opened by a vertical incision above the pubes on a sound, the peritoneum being carefully drawn out of the way.

McGill adopted in his cases a transverse incision through the skin and recti muscles, and also into the bladder; but the writer found that the vertical incision gives plenty of room, and the recti can be partially divided transversely, if necessary, and then drawn outward. The walls of the bladder are now held apart and the cavity opened out by three long, curved metal retractors, and by these means and upward pressure on the bladder by the assistant's finger in the vagina the fistula and field of operation can be brought well within reach; the thin cicatricial junction of the two mucous membranes is now incised all around, and two flaps of vesical mucous membrane are raised, one on either side of the rent, with their edges turned inward towards the bladder, and are sutured with catgut on a double-curved needle, such as is used for cleft-palate suture; at this stage the rectangular knives and long forceps are also useful, and care must be taken at the angles to extend the separation of the mucous membrane beyond the actual limits of the fistula.

A few silver-wire sutures are afterwards used to draw the edges of the vaginal mucous membrane together, these having been already freshened on their vesical surface by the operation within the bladder.

It is very important in the after-treatment to

avoid the occurrence of cystitis, for which purpose continuous irrigation of the bladder, day and night, with warm boracic solution is very useful. It is carried out as follows:

After the closure of the fistula, a piece of india-rubber tubing, or a large Jacques catheter, is passed through the urethra and drawn out above through the suprapubic wound, and to the upper end of this is attached the nozzle of the irrigator tube. The tube within the bladder has a few lateral holes cut in that part of its course which lies within the cavity of the viscus, and these allow of a free current of lotion both inward and outward. The cavity can be distended and flushed at will by compressing the tube beyond the urethra; the rate of flow can be easily regulated by pressure-clamps and the irrigator kept constantly warm by a cotton-wool jacket. This irrigation can be continued as long as necessary. The tube can be gradually dispensed with, by first drawing it within the bladder and allowing the suprapubic opening to close, and then removing it entirely.

The portion of tubing projecting from the urethra should be sufficiently long to reach a receptacle, in order to avoid wetting the bed.

In addition, Bond found this continuous irrigation very useful in other cases of suprapubic cystotomy, in which the bladder has been drained by a tube passed through the membranous urethra, the continuous current of the acid lotion preventing the deposition of phosphates in and around the wound.

The suprapubic method offers a surer means of closing the fistulous opening in bad cases: first, because the vesical flaps when raised and turned inward have their surfaces opposed to the direction of the current of urine flowing through the fistula, and are thus more tightly closed by its pressure, unlike the flaps formed by vaginal mucous membrane; the vesical flap is the valuable agent in closing the opening, and it is in proportion to the care taken to thoroughly free and separate these that success depends, even in operating through the vagina. Moreover, in most cases of extensive loss of substance, the vesical mucous membrane has grown over the edge of the fistula, projecting into the vagina, and is more voluminous than the vaginal membrane.

Secondly, the suprapubic opening, especially where combined with the urethral drain and constant irrigation, insures complete drainage,—that is, the absence of all tension within the bladder. This is a most important factor, and is in itself sufficient in some cases to bring about cure without further operation.

Such an opening is a far more effectual form

of drainage than the introduction of a self-retaining catheter only, which is almost sure to induce cystitis.

#### REPLANTATION.

The operation consists in replacing in its socket a tooth which has been partially or completely dislocated. The union after replantation is brought about through the periodontal membrane. In cases where the tooth is living and immediately replaced, a re-establishment of the vitality of the pulp is sometimes produced. Magitot, who has recorded a large number of cases of replantation, maintains that, for success, there must be a complete ring of healthy membrane on the tooth. Results depend upon the nature of the conditions for which the operation is undertaken. If for traumatism, and the tooth is immediately replaced, a permanent result may be looked for; but, on the other hand, if replacement is delayed, the prognosis is naturally not so good.

HARRISON (*Quarterly Medical Journal*, vol. ii., Part IV.) has had four such cases, and reports in detail an interesting case illustrating the above statements.

#### ELECTRO-PUNCTURE OF THE TONSILS.

STRAIGHT (*Western Reserve Medical Journal*, vol. iii., No. 1) states that a fair trial of both electro-puncture and excision has led him to an almost entire use of the latter. Galvano-puncture is a very painful procedure, in spite of painting the tonsil with a 20-grain solution of cocaine. The injection of cocaine into the tonsil seems hardly justifiable for an operation that must be repeated so many times.

The tenderness after electro-puncture is often very great, and the patient complains bitterly for a number of days. The tenderness after excision is, as a rule, almost wanting after twelve hours, if the tonsillotome is sharp and the stump of the tonsil is not bruised. Many cases, twenty hours after tonsillotomy, say that the throat feels much less uncomfortable than before the operation, and that the tenderness that was almost constantly present, especially after the least cold, was greater than that from the excision. It might be urged that the writer has made too free use of electro-puncture in his cases. He has cauterized deeply and at other times superficially. When he cauterized carefully, he accomplished next to nothing. When he cauterized deeply and made a number of punctures, the tenderness following was much

interference, extirpation is preferable to operative fixation.

Severe traumatism of the spleen, with or without an external wound, or simple prolapse of the gland into a parietal wound, demand, as a rule, immediate extirpation. In cases of protrusion, experience shows that excision, partial or total, is a safer procedure than mere replacement.

Removal of the spleen for cystic disease has an excellent record, but most authors advise a preliminary trial of incision with drainage. In abscess it is better, except in rare cases, to incise and drain than to attempt removal of the organ.

#### OSTEOPLASTIC RESECTION OF THE SACRUM.

It is now generally admitted that the only way of dealing effectively with certain ailments of the rectum, especially in its upper parts, is by approaching the seat of disease from the posterior wall of the pelvis. KAMMERER (*Medical Record*, July 28, 1894), with this sentence, begins an able article recording in detail six operations performed by himself, with satisfactory results. He advocates Rydygier's procedure, which is as follows: The soft parts are incised, beginning at the posterior superior spine of the ilium on the left side and running down to the tip of the coccyx, thence in the median line to the anus. After division of the sacro-sciatic ligaments, the soft parts are removed from the anterior surface of the sacrum by the hand of the operator. A transverse incision is then added below the third sacral foramen, and the bone divided along this line with a chisel. A flap is now turned to the right side. With a retractor inserted at the tip of the flap, the latter can be easily held aside and manipulations about the rectum can be as readily carried on as when the bone has been entirely removed. The author has been impressed in all his cases with the rapidity with which this preliminary operation can be done and the absence of profuse hemorrhage. He fully endorses Rydygier's claim that his osteoplastic resection is a much less bloody operation than the permanent removal of coccyx and sacrum by any one of the other methods, with dissection of the soft parts from the posterior surface of the sacrum. In only one instance did Kammerer meet with considerable hemorrhage; here he operated in the lateral position. The knee-elbow position was employed in all the other cases, with distinct elevation of the pelvis, especially of the sacral region, the writer declaring this to be the most

desirable one for rectal surgery, since it controls hemorrhage through elevation, gives excellent access to the field of operation, the surgeon standing between the slightly separated thighs of the patient, also facilitating manipulations with the chisel, the pelvis being supported by sand-bags placed under the anterior iliac spines.

When the flap, including the coccyx, part of the sacrum, and the integuments, can be, from the nature of the case, returned to its place and sutured, the result will be an ideal one as regards restitution of the normal contour of the sacral region. In suturing the transverse incision the author always passes the needle down to the bone, but never includes the bone itself in a suture by any device whatever. Notwithstanding, in several cases in which he has had to elevate the flap a second time, he has always found firm union of bone surfaces, either fibrous or partly osseous. It is unfortunate that secondary operations so frequently become necessary in rectal surgery, for even when we have resected the rectum and made a circular suture of the ends, we frequently find that the latter gives way on the posterior circumference of the bowel. The operation of raising the flap a second time is no more tedious than the first. Greater care must be exercised to avoid the rectum, which now has been drawn close to the anterior surface of the sacrum by cicatricial contraction. When we are dealing with cases, such as fistula, where tamponade of the wound-cavity becomes necessary for some time, we should not suture the flap, but leave the wound-cavity entirely open. The author had good proof of the advisability of this procedure from his fourth case, where he got very good union of the transverse and vertical incisions, but in which a successful tamponade of the deep wound-cavity (about six inches) was not easily effected through the small opening corresponding to the unsutured part of the original incision. To this fact he attributes the ultimate re-establishing of a small vaginal fistula. Such wounds ought to heal from the bottom of the wound-cavity, to avoid even the slightest retention endangering the object in view, and the best guarantee for this is a wide opening, allowing free inspection and tamponade.

Where no sutures are used, some retraction of the flap develops after a time. There is no doubt much less than in flaps that are without a bony substratum. Even when only the lateral incision to the left of the sacrum has remained open, a distinct elevation of the soft parts over the sacrum results from the same cause,—a deformity which can, no doubt, at the proper time, be very readily remedied by an insignifi-

cant plastic operation. This is not so readily accomplished when no suturing at all has been done.

After some time secondary operations on the rectum are even more difficult than the original ones, owing to the development of much cicatricial tissue about the gut, which makes the latter more rigid, and does not, in consequence, permit the approximation of such parts which we may desire to unite by sutures. From all this we may conclude that it will be wise to do secondary operations as soon as the condition of the patient will permit.

The cases of fistula reported have not been entirely cured. They have been much benefited, and one of them is very likely closing. An anterior laparotomy would certainly have been unwise in any of them.

While technically difficult, the sacral route is still the easiest way to get at the seat of disease when the rectum is affected, and also in some cases in which the uterus is to be dealt with. Rydygier's preliminary operation is certainly well devised, and being as simple as the permanent resection of the sacrum, while not disfiguring, assuredly deserves preference.

#### HYPERSECRETION OF THE SWEAT-GLANDS OF THE FEET.

Against sweating feet, LÉGOUX (*Therapeutische Blätter*, Wien, July, 1894) recommends,—

R. Liquor ferri sesquichlor., 30;  
Glycerini, 10;  
Ol. bergamot, 20. M.

Sig.—Apply with a brush each morning.

#### DANGERS OF GLYCERIN INJECTIONS INTO THE UTERUS FOR THE PURPOSE OF INDUCING PREMATURE LABOR.

EMBDEN (*Medical Record*, July 28, 1894) gives an extract of Pfannenstiël's article concerning the dangers connected with intra-uterine injections of glycerin for the purpose of inducing premature labor, and reports the history of two cases treated by the same writer, as well as one of his own. As a result of the above studies, he concludes that Pelzer's method is liable to occasion indisputable symptoms of glycerin-poisoning. This will be a death-blow to the method.

Concerning the first case, the glycerin cannot be considered the cause of the woman's death, as she suffered from nephritis. It is, nevertheless, remarkable that there was found a small

quantity of blood-colored water in the bladder, the urine being entirely free from blood in the last days before the injection was performed, as shown by frequent examinations. Pfannenstiël tries to find the cause of this in the injected glycerin.

The second case was undoubtedly a case of glycerin-poisoning, and although it did not damage the future health of the woman, it kept her in danger for some time. The woman was in perfect health up to the time of the injection; the urine was normal. One hour afterwards she had symptoms of glycerin-poisoning.

In the author's case there was a woman with nephritis, but there was not noticed at any time before the injection any trace of blood in the urine. After the delivery there was a good quantity of a dark-red urine in the bladder. In examining the same, Embden failed to find any red blood-corpuscles, but there was a large amount of hæmoglobin. The explanation of this appears to be a decomposition of the blood, brought on by the injected glycerin.

This does not seem so very strange, as we know—according to Pfannenstiël—that glycerin is liable to occasion a decomposition of the blood, as has been shown by numerous experimenters with dogs and rabbits, the hæmoglobinuria caused by glycerin bringing on a glomerulo-nephritis, followed, after the injection of more glycerin, by interstitial nephritis as well as by interstitial hepatitis.

It is, of course, strange that neither Pelzer nor others met with a similar accident after injections of glycerin.

Pfannenstiël finds an explanation of this in the fact that Schwan, Lebedeff, and Filehne have shown that in rabbits, when the glycerin is brought under the skin, hæmoglobinuria always occurred, but that it did not occur, or in a slight degree only, when it was injected directly into the veins. Without giving an explanation of this, Pfannenstiël deems it possible that, in Pelzer's cases, the glycerin was very rapidly absorbed by the circulatory system, while in his cases it acted in the decidua uteri as if it had been injected by the hypodermic method.

The writer's case is particularly interesting from the fact of the icterus following the hæmoglobinuria. It seems indisputable that this was caused by the decomposition of the blood poisoned by glycerin. The writer rather leans to the belief that the semi-comatose condition which appeared in his patient was brought on by the same cause; it did not look like a uræmic coma. Another danger of the injec-

tion of concentrated glycerin is the possibility of a thrombosis. Another objection to this method, in common with all injections of fluid of any kind between the uterus and the foetal sac, is the possibility of air entering the circulatory system.

Finally, the writer asserts that Pelzer's method should not be used at all for the purpose of inducing premature labor; more especially is it to be avoided in cases of nephritis.

#### FISTULA OF THE STOMACH IN A CHILD.

A child aged six years swallowed by mistake some hydrochloric acid, following which developed an oesophageal stricture, and gastrotomy was performed. Later gradual dilatation of the oesophagus was practised, and eventually food was introduced by means of a catheter passed through the mouth. At the time he was brought to the service of Dr. CHORON (*La Presse Médicale*, July, 1894) the patient was suffering from marasmus and emaciation threatening his life, and closure of the artificial opening was attempted to stop the continuous outflow of gastric juice and mucus, which was causing an eczematous condition of his entire abdomen.

The stomach was irrigated with a three-per-cent. solution of boric acid. The opening was excised, with a small collar of skin around it. The opening in the abdominal wall was now enlarged towards the left costal border.

With curved scissors the stomach was separated from the abdominal wall. A wound of the liver was tamponed to arrest hemorrhage.

The stomach was sutured with catgut, the other structures with silk (No. 1); first a Lembert suture to the serous membrane, then the muscles and skin received each a separate suture.

#### TREATMENT OF CHRONIC GONORRHEA.

Before the Society of Internal Medicine at Berlin, ROBERT KUTNER (*La Presse Médicale*, July, 1894) demonstrated the advantages of graduated instillations, basing his reasons upon two observations: 1, that gonorrhœa in the chronic form shows itself in circumscribed places; 2, that the introduction of the olive-tipped sound produces more pain at these localities than at other points in the canal.

First, with a *bougie à boule*, he measures the distance of these sensitive spots from the meatus. He then introduces a syringe with a hollow sound adjusted to the point, and applies silver nitrate (one per cent., ten per cent., or twenty

per cent.) or copper sulphate to the spots previously located by his measurements.

The advantages of this method are,—

1. Exact location.
2. Energetic action of the medicine exactly placed.
3. Less reaction.
4. Economy of time.
5. Simplicity of the procedure.

#### TREATMENT FOR ACNE VULGARIS.

PHILIPPSON, in *Therapeutische Monatshefte*, November, 1893 (*Monat. Praktische Dermat.*, July, 1894), says that the causation of acne is still so uncertain that the treatment must be symptomatic.

The pustules are opened and the contents pressed out; then he cuts through the induration; over this a fifty-per-cent. salicylic plaster is laid. Compresses of lead-water and acetic acid soften the skin, cause the pustules to disappear, and relieve the irritation.

For the milder forms, soap, salicylic acid, naphthol, resorcin, and sulphur are recommended.

The following formulæ are used at Lessor's clinic in Berlin:

1. R Naphthol, 10 parts;  
Vaseline,  
Saponis viridis, of each, 20 parts;  
Sulphur præcipitatis, 50 parts.  
M. et fiat pasta.
2. R Camphor trit.,  
Vaseline, of each, 10 parts;  
Pulv. cretæ albæ, 5 parts;  
Saponis viridis, 15 parts;  
Sulphur præcip., 50 parts.  
M. et fiat pasta.
3. R Resorcin,  
Amyli puri, of each, 5 parts;  
Vaseline, 15 parts;  
Zinci oxidi, 5 parts.  
M. et fiat pasta.

These pastes can be applied until inflammation follows, or can be washed off in a quarter to a half-hour, and can be followed by powders.

The first two are best used in the latter manner, while the third is milder. For the mildest forms, where single pustules are found, the following wash is used:

- R Acid. acet. conc.,  
Tinct. benzoës,  
Spirit. camphor., of each, 6 parts;  
Spirit., q. s. ad 100 parts. M.  
Sig.—Apply with sponge night and morning.

*PELVIC EXUDATE.*

In a series of papers with the above title, PROFESSOR BIRNBAUM closes with the following therapy (*Der Frauenarzt*, July 7, 1894):

The best prophylaxis is a thorough antiseptic handling of each childbirth, each operation, or other manipulation of the genitalia.

The special treatment is necessarily local, since the fever and constitutional symptoms are dependent upon the local process.

Of prime importance is the removal of irritation or anything causing congestive changes or which obstructs the backward flow of blood, and avoiding unnecessary movements or internal examinations.

So long as fever and pain denote continuance of inflammation, cold compresses, ice-bags, or water of moderate temperature are employed to counteract it.

Kisch recommends for the acute stage intravaginal applications of cold by means of a special irrigator.

For plethoric patients bloodletting is recommended early in the childbirth by applying from six to ten leeches in the inguinal region of the affected side.

Not so strongly recommended is the use of leeches to the vaginal wall, owing to the irritation and the danger of infection.

The ice-bag is used only so long as the pain continues; then water compresses (22° to 25° C.) are resorted to, which may be continued for hours, under which treatment the absorption often goes on to completion.

The much-lauded use of unguent. cinereum, or ointment of potassium iodide, has yielded less prompt results than the water applications.

Where foul-smelling lochia are present, the vagina is washed out many times a day with sublimate (one-tenth per cent.) or carbolic-acid solutions (one to two per cent.).

For the fever, when it is very high and persistent, large doses of cinchona, antipyrin (cautiously), sodium salicylate, digitalis with acid, and the like drugs are employed.

If, in spite of this, the exudate goes to pus-formation, it is still possible to have absorption by the use of compresses. But when the continued high fever denotes the presence of pus, then drainage of the collection is required.

When there is a tendency to point externally, applications of flaxseed poultices, etc., are made.

When fluctuation is detected, an incision is made above Poupert's ligament, from one to two centimetres and two to three centimetres from the anterior superior iliac spine.

When fluctuation is not positive, exploratory puncture is recommended.

From the rectal region it is more difficult to remove the collection, but exploratory puncture may also be tried through the vagina. After opening in this situation, it is well to employ drainage.

When the abscess breaks into the rectum or bladder, without sufficient drainage, Byford recommends inserting a sound through the abscess opening, turning the point against the vaginal wall and cutting against the point of the sound.

If the exudate does not go on to pustulation, then iodine, internally as well as externally, is employed.

Painting with tincture iodi, inunctions of iodine, and potassium iodide ointment, or the rubbing of potassium iodide and lanolin into the abdominal wall.

Painting the cervix and vaginal mucous membranes with the tincture of iodine, or with iodine and glycerin, followed by dusting with iodoform, is also advised.

In anæmic patients the use of iodine must be guarded.

After iodine, cold, lukewarm, or hot irrigations, with or without addition of medications, are recommended.

The use of massage is recommended with caution, suppuration contraindicating this.

Electricity has not proved a success.

Mercury as inunction and internally is used where gonorrhœal cause is suspected.

Naturally, in each case good diet, iron, quinine, wine, and similar tonics must be used, and the patient must not be allowed to leave her bed too early.

---

*THE VAGINAL ANUS AND ITS TREATMENT.*

BUCKMASTER (*New York Medical Journal*, August 11, 1894) gives a carefully condensed report of the literature throwing light on this much vexed subject, with a detailed description of the methods he has employed in overcoming the deformity.

There are so few cured cases that it is easy to explain the attitude of conservative men towards operative procedure. It is important to classify the cases, that we may determine which are fit for operation. It is convenient to divide the cases into two classes. The first class comprises those patients who have control, and the second class includes those patients who pass their fæces involuntarily. The first class is not large in number, and if the patient will take

precautions to preserve cleanliness, and if the opening is large enough to pass formed fæces, operation is not advisable. A douche after each movement will in some cases prove sufficient to keep the patient comfortable. If such precautions are neglected, the mucous membrane of the vagina will become excoriated and abscesses may form in the connective tissue. If, in spite of this advice, the patient should still desire an operation, the results are sufficiently good and the dangers under sufficient control to warrant compliance with her request.

The second class, or those who have no control, includes the great number of cases. Most of them are recognized shortly after birth, and unless the opening is so small that it obstructs the passage of fæces, nothing need be done until a later time. Fæcal matter in healthy young infants is quite unirritating, but as the character of their food changes it may cause great trouble; for this reason careful attention should be given to the diet. It is easier to mould the tissues after the child is fifteen years of age than before this time, but it is not necessary to wait on this account.

In considering the dangers of the operation, we must not forget that all of the fatal cases occurred in a day before antiseptic surgery was understood. The operation the author describes is not more dangerous, he states, than that used to restore a ruptured sphincter. It is used particularly in those cases where there is no control. In cases where the patient has control, and it is necessary to free the bowel for some distance, there is more risk. A number of deaths have been recorded, but with the better technique of to-day the risk is no longer great if the patient be healthy.

The first step in the operation is to introduce a probe into the fistula from the vagina, and bring out the point of this instrument just above the levator ani muscle, the tissue above the probe being divided. The skin should be pierced in front of the lower part of the sling formed by the fibres of the levator ani muscle. The location of this muscle should be ascertained, if possible, before the patient is etherized. When the tissues above the probe have been divided, the rectum is seen, is divided, and may be slightly freed by a few strokes of the knife. It must be remembered that the backward extent of the incision only indicates the backward limit for the plane in which it is found; the skin is divided about an inch farther back.

The next step is to draw the rectum to the skin, and here one is very apt to make a mistake.

The rectum should be fastened to the skin without strain. If proper ligature material be used, and the strain is not too great, the sutures will never cut out, but will become embedded in the tissue, as is the case in all plastic work. On the second day after the writer first operated, he found that the strain had been too much for his stitches, and was obliged to cut those at the sides and place a new one in the middle of the wound; this entirely removed undue tension. If the tension had been too great, he would have drawn the rectum down as far as possible without strain, trusting to a future operation to reach the skin. By careful attention to this caution we can never fail to gain something, and it is only a question of time when the rectum can be securely anchored to the skin. It is important to bear in mind that if union of the rectum to any point of the skin is secured, no matter to how slight an extent, it is not a difficult matter to bring the remainder of the circumference of the bowels in the desired position at a later period.

Having united the rectum to the skin, the raw surfaces left at the side are sewed together. After the completion of the first step, the rectum opens below the vagina, and no raw surfaces are left. The patient can be on her feet in ten days.

The second step of the operation consists in forming that part of the pelvic floor which is usually known as the perineal body. It will differ very much in different cases, as the distance between the abnormal opening and the urethra varies. It cannot be properly done except by an operator who is a good plastic surgeon.

The third step suggests itself on theoretical grounds; the author has not yet had opportunity to put it into practice. He means to split the fibres of the levator ani muscle, as has been done with the rectus muscle in gastrotomy. If this is practicable, we ought to obtain a fairly good sphincter. It is not unlikely that those cases which have gained control after operation have done so by having the muscle, which has been divided, grow about the rectum.

#### FIXATION IN THE TREATMENT OF FRACTURES INTO JOINTS.

In an interesting discussion of this subject by COOK (*International Journal of Surgery*, August, 1894) the following conclusions and rules of treatment are laid down:

1. That bony or serious fibrous ankylosis is the result of injury and subsequent inflammation and not of immobilization.

2. That early passive motion only disarranges the fragments of bone, thereby increasing the production of callus; that it irritates the injured ligaments and, by increasing the inflammation, tends to produce the ankylosis it is thought to prevent.

3. Immobilization is useful only when active inflammation is present, or until the ruptured ligaments and broken bones have thoroughly united.

4. The logical treatment of a fracture into a joint, therefore, should be rest and local applications to reduce inflammation. Reduction of the fracture as early as possible, then immobilization until the bones and ligaments have united (from three to eight weeks, or more, according to circumstances).

5. Passive motion, massage, and use till the tissues become normal, or, if the massage fails, complete rupture of all adhesions under an anæsthetic. The factors which will ultimately determine ankylosis are the nature of the original injury, the character and duration of the subsequent inflammation, the destruction of bone and cartilage, cicatricial contraction of the soft tissues around the joint, and the age and condition of the patient.

#### DANGERS OF THE LONG RECTAL TUBE.

It has long been a disputed question as to whether the long rectal tube can safely be passed into the sigmoid flexure. In this relation the opinion of MR. HARRISON CRIPPS in a recent number of the *British Medical Journal*, is of interest.

In spite of the condemnation of the long rectal tube by Brodie, Treves, and many other eminent authorities, he still finds that in most cases of obstruction or supposed obstruction the tube has been introduced. Fortunately, these tubes are fairly soft, so that in a capacious rectum, when they impinge and are arrested about opposite the promontory of the sacrum, they simply coil up and do no harm. If stiffer ones are used, the patient's life is placed in imminent risk. A patient at St. Bartholomew's Hospital was to be operated on for ruptured perineum. In order to increase the supposed efficacy of the injection, a quart of soap and water, with some ounces of oil, were injected by means of a long tube; the injection never returned. A few hours afterwards, owing to the acute symptoms, Mr. Cripps assisted one of his colleagues in opening the abdomen. The soap and water and oil were found in the abdominal cavity, and a hole below a reduplicated fold in the upper part of the rectum.

The patient died. He says that the idea that these tubes can be generally passed into and beyond the sigmoid flexure is a pure delusion, save in the rarest circumstances. As a means of diagnosis, or of treatment of stricture beyond the reach of the finger, tubes of any kind are absolutely useless. If a stricture is actually present, it would be 100 to 1 against the long tube or bougie entering it, for it would almost certainly catch in the cul-de-sac generally caused by the invagination of the stricture. If a stricture is not present, the arrest of the bougie by the sacral promontory leads to delusive diagnosis. Brodie, in his lecture, alludes to a case in which a worthy practitioner had spent over one hundred and fifty hours in dilating a supposed stricture situated high up. The treatment had extended over a period of a year. Brodie, who was present at the post-mortem examination, found that there was no sign of a stricture, the bougie becoming arrested by a curve of the sacrum.—*Boston Medical and Surgical Journal*, September 13, 1894.

#### THE TECHNIQUE OF CURETTAGE.

M. SÄNGER (*International Journal of Surgery*, September, 1894) states that, aside from the infectious, gonorrhœal forms of chronic endometritis, the most frequent and important varieties are endometritis, menorrhagica, and hypersecretoria. For the former (endometritis interstitialis, fungosa, climacterica) the best treatment consists in curetting, followed after a few days by the application of caustics. In endometritis hypersecretoria, which is usually limited to the cervix uteri, irrigation, gauze "drainage," and cauterization are especially indicated. Irrigation must be preceded by dilatation of the cervix with laminaria tents, and rarely effects a cure unless associated with other measures. As a preparatory procedure to cauterization, washing out the uterus with a soda solution is of service. The use of gauze tampons, especially of medicated gauze, has a favorable action, although they should not be regarded as promoting drainage. They have the disadvantage of requiring to be frequently renewed. This objection does not apply to cauterization; the stronger the caustic the less frequently it has to be repeated. Säger believes that in general the cauterization resorted to is too mild and too frequently repeated. Among caustics he prefers a fifty-per-cent. solution of chloride of zinc, which is suitable for catarrhal as well as chronic, infectious, and menorrhagic forms. In cases where the cervical canal is narrow, however, in virgins and

nullipara, weaker solutions are in place. If a fifty-per-cent. solution be employed, the application should not be repeated until the end of sixteen to twenty days. For cauterization, Snger employs a long, thin, silver sound.

#### DIAGNOSIS AND TREATMENT OF PROSTATIC ENLARGEMENT.

BELFIELD (*Indian Medical Journal*, August, 1894), in the following sentences, expresses his views on this subject :

While the etiology of prostatic enlargement still remains a matter of speculation, it is certain that the earliest clinical symptoms are due to vascular engorgement of the prostate and, by consequence, of the bladder. The actual increase in the size of the gland should not obscure the other factors in producing the symptoms, which may be out of all proportion to the perceptible enlargement. The factors contributing to the familiar symptoms associated with prostatic enlargement are :

1. Venous congestion and dema of prostate and bladder.
2. Fibroid thickening of the vesical (prostatic) sphincter, often extending to the detrusor and to the prostate.
3. Suppuration in the prostatic urethra (glands and utricle).
4. Hypertrophy of the prostatic elements (glandular or muscular, or both).
5. Chronic retention of urine, due to any one or all of these four antecedent conditions.

The most important as well as the most difficult task in diagnosis is the differentiation among these various morbid states ; for the prognosis as well as the treatment is determined by the predominance of one or another of them. For example, a prostatic patient complains of frequent and painful urination ; the chief trouble may be an aggravation of the usual venous congestion, in which case a brisk laxative, suppositories of ichthyol, and ergotin and strychnine internally will secure speedy relief. Again, the symptoms may be due to prostatic suppuration, in which event irrigation of the deep urethra with hot water containing hydrastin or silver nitrate is needed ; or the frequent urination may be simply the overflow of a distended bladder, which is relieved by the cautious daily use of a clean catheter.

It should be remembered that the symptoms clinically associated with prostatic hypertrophy depend upon several distinct morbid conditions, of which the mechanical impediment to the exit of urine may be the least ; and that no

routine treatment can be prescribed, the requirements varying with the case.

Our resources for meeting the needs of different patients may be thus summarized :

1. *Medical*.—(a) Improvement in the blood circulation through prostate and bladder is favored by proper diet and exercise, avoidance of constipation, massage of prostate between a sound in the bladder and finger in rectum, and by the daily use of a clean catheter ; internally, ergotin and strychnine are certainly useful.

(b) Suppuration in the bladder neck requires irrigation of the prostatic urethra with hot water, solutions of hydrastin, silver nitrate, etc., in addition to the measures already mentioned.

(c) Induration and distortion of the bladder neck may be improved by dilatation with large sounds or a special dilator.

In a certain percentage of cases the time arrives, sooner or later, when these measures fail to relieve, and more efficient and immediate aid must be rendered.

2. *Surgical Methods*.—(a) The simplest is puncture of the membranous urethra from the perineum and introduction of a drain, which is permitted to remain for a couple of weeks. The subsidence of congestion and dema, and the cleansing of the bladder thus induced, sometimes makes an apparent cure for many months. Puncture with a trocar through the prostate (Harrison), or drainage of the bas-fond behind the organ, is even more desirable.

(b) By a perineal urethrotomy the surgeon can secure not merely drainage, but also thorough digital stretching of the prostate and the incision or excision of obstructions at the orifice of the bladder.

(c) More satisfactory excision of prostatic obstructions has been accomplished by a combination of suprapubic cystotomy with perineal urethrotomy,—now a standard operation.

Within the past year there have been reported attempts to relieve the sufferings of the prostatic by securing atrophy of the enlarged prostate ; by Bier, through ligation of the internal iliacs, and by Raum,\* through castration. Bier reports three cases ; in one, death from septic peritonitis occurred ; in the remaining two, marked reduction in the size of the gland and decided improvement in symptoms

\* The credit of proposing castration as a means of producing prostatic atrophy undoubtedly belongs to Dr. J. William White, though Raum was probably the first to make a practical application of the proposal on man.—Ed.

are reported. Castration alone is said to have accomplished a cure in Raum's two cases.

Two new operations upon the enlarged prostate itself have been recorded; one by Nicoll, who made a submucous removal of the entire prostate from the perineum in two cases with good result; the other, by Belfield, combines the removal of any part or all of the prostate with perfect drainage of the bladder and deep urethra. By incision into the ischio-rectal fossa, the prostate and trigone are laid bare and incised in the median line; each half of the prostate can be enucleated to any desired extent. A suprapubic incision—robbed of its danger by the perfect drainage secured through the posterior wound—can be made, if required for freedom of manipulation. This operation seems to meet all the indications of all cases. Like most other operative procedures, it is undoubtedly too severe for feeble patients to endure.

#### ABSCESS OF THE APPENDIX.

During a recent clinic MCBURNEY (*International Journal of Surgery*, September, 1894) presented a case of more than usual interest and one rarely met with. Three weeks prior to admission the patient had been in good health, when she was seized with a pain in the right iliac fossa, together with nausea and vomiting. The pain continued to increase in severity up to the time she entered the hospital, ten days before. She had a temperature of 101° F., pulse rather feeble, abdomen slightly tender on pressure, but with the walls relaxed. On palpation, a tumor in the right iliac fossa could be readily felt, which was not adherent to its walls, nearly spherical in shape and nodular in character. The history of the case was not of much aid in arriving at a diagnosis. There was no reason to believe that the tubes and ovaries were affected, and although the tumor was situated very near the pelvis, it did not extend into that cavity. There was no distention or obstruction, such as would be caused by a tumor in or around the intestine, thus pointing to the origin of the tumor as an abscess of the appendix.

As the patient was not suffering from high fever, nausea, or distention, the trouble being entirely localized, operation was postponed. The next day the tumor had entirely disappeared, and, unfortunately, no attention had been paid to the character of stools, which might have afforded an explanation of this occurrence. There is no doubt that she had an abscess of the appendix, which evacuated itself into the intestine through a new passage. The

patient was in a more comfortable condition and the pain entirely allayed. Close examination of the abdomen revealed an induration of the tissues at the site of the original tumor. The patient continued to have fever, though somewhat reduced in intensity since that time. Her condition remained about the same. Slight abdominal tenderness, but no distention, was present, and the bowels were active. In cases of this kind, where the abscess has burst into the intestine, some patients have continued in good health and been entirely cured. On the other hand, cases with this history sometimes suffer from repeated recurrences, until an operation has been done for their final cure. In such cases, on cutting down, the reporter has found the appendix entirely separated and lying quite loose in the mass of connective tissue forming the wall of the abscess, the opening in the gut still existing.

Therefore, McBurney advised operation in the above case. He calls attention to the fact that cases of appendicitis differ very greatly in character. Incisions made through the abdominal wall must be adapted to the requirements of each case. In some cases the appendix can be removed with perfect ease through a very small incision, say one and a half inches in length, but to apply such a method, as recently described in some of the journals, indiscriminately to the different cases, and to adopt a standard incision for abdominal section, is useless. The incision must be adapted to the character of the case to be operated on; we should not accept any method of entering the peritoneal cavity through a small opening in operating for an extensive disease. If we know by experience that the disease is small in extent, then we can remove the appendix through a small aperture with advantage. This, of course, does not apply to the cutaneous incision.

The operator, after cutting down to the appendix, found an abscess cavity. The appendix was removed and the opening in the intestine sewed up. The patient was in such a condition that the removal of the diseased appendix seemed the only course to prevent an imminent attack of appendicitis.

#### CÆLIOTOMY IN TYPHOID PERFORATION.

A case of operation of this nature is reported in the *British Medical Journal*, No. 1783. The patient was in the fourth week of the typhoid fever. Symptoms of perforation developed, attended by collapse. The abdomen was opened as soon as the patient reacted. Perforation was

The bismuth is added to prevent irritation of the mucous membrane of the rectum.—*Medical and Surgical Journal*, August 4, 1894.

#### VOMITING OF PREGNANCY.

A writer in the *Lancet* says, "I have not failed once for many years, by a single vesication over the fourth and fifth dorsal vertebræ, to put an end at once to the sickness of pregnancy for the whole remaining period of gestation, no matter at what stage I was consulted. The neuralgic toothache and pruritus pudendi of the puerperal condition yielded as readily, and to one application."—*Medical and Surgical Journal*, August 4, 1894.

#### IVY-POISONING.

A current number of the *Sanitarian* advises the application of Labarraque's (solution of chlorinated sodium) solution in this irritating affection. It should be applied in full strength by means of a pledget of lint or diaper cloth kept constantly wet with the liquid; it will afford relief immediately.

#### SEPTIC OSTEITIS IN CHILDHOOD.

A lecture on this subject was recently delivered by Mr. EDMUND OWEN at the London Hospital for Sick Children, and is reported in the *Lancet* for May 26. Mr. Owen believes that a diagnosis of rheumatism is sometimes erroneously made, when the condition present is, in fact, osteitis due to some septic infection. This may occur without a history of local injury, but usually some illness has seriously disturbed the patient's nutrition. In such circumstances all the tissues of the body are rendered uncommonly susceptible to infection, and it is not strange that the delicate new bone at the end of the diaphysis should suffer. Any septic micro-organisms which have gained entrance into the body might readily implant themselves in this region of slight resistance. Here they would undergo prolific cultivation, secreting their ptomaines to poison the blood and disturb the nervous system. Two cases were presented illustrating this condition. In neither case could a satisfactory cause be discovered. Sometimes the disease is acute and fulminating, and carries the child off before a diagnosis has fairly been made. In others, as in the cases mentioned, it is slow, and simulates articular rheumatism in many respects. Unlike rheumatism, however, the heat, the swelling, the pain,

and the tenderness, although close to the articular area, do not involve it. The tenderness is limited to the region of the bone close below the junction cartilage, and at this point there is a definite thickening. In articular rheumatism the swelling, the fulness, and the redness are confined to the area of the synovial membrane, and there is no thickening about the bone; the results of treatment also aid in diagnosis. The relief of the symptoms of acute rheumatism is, as a rule, so prompt under the use of salicylic acid that an increase in the severity of the articular signs, or even a lack of any improvement after a few days, should arouse suspicion and call for a more thorough and careful investigation. The diagnosis should be made as promptly as possible, for error and delay lead to lamentable results. The treatment is essentially surgical. Incision should not be delayed until the presence of pus is demonstrated. Delay allows the septic inflammation to make irremediable havoc, so that the sooner the area of disease is attacked and cleared out the better. To wait for fluctuation is to give the staphylococci and other micro-organisms full opportunity to do their worst. The incision should be through the periosteum, and, if any pus is here confined, a free opening should be made. The diaphysis should be trephined to give free exit to all septic matter pent up within the bone.—*New York Medical Journal*, August 4, 1894.

#### SPLENECTOMY.

CONKLIN (*Medical Record*, July 28, 1894) reports a successful splenectomy. The patient, Mrs. A., American, aged twenty-nine, married, multipara, was admitted into St. Elizabeth Hospital, May 29, 1893. Her family record is without taint, menstruation normal, and general health but little impaired. Mrs. A.'s early life was passed in a highly malarious district in Southern Illinois, and up to her marriage and removal to Ohio she was subject to frequent attacks of chills and fever, and carried almost constantly an "ague cake" in her side. She had been free from malaria for several years, and, aside from an attack of typhoid fever, has had no serious acute illness. Two years before she began to have abdominal and pelvic pains, and some months later discovered a lump low in the abdomen. Examination disclosed a solid, freely movable tumor, sensitive to touch, in the left iliac region, dipping into the pelvis, but not connected with the uterus, and a small cyst of the right ovary. The uterus was normal in size, but retroverted.

Dr. Jewitt made a coeliotomy June 10, 1893. The solid tumor proved to be a displaced spleen about twice the normal size. It was free from adhesions and easily replaced. The right ovary, containing a cyst the size of a small orange, was removed; left ovary normal; convalescence was uneventful. She was soon discharged, with positive instructions to wear constantly a properly fitting abdominal supporter, with the hope of retaining the spleen in position.

Mrs. A. was readmitted into the hospital during the author's service, September 23, 1893. Shortly after her return home she again began to suffer from pelvic symptoms, and for the past two months had nearly continuous abdominal soreness and several severe paroxysms of pain, which drove her to bed. Her abdomen had been steadily enlarging.

Six days ago, while doing the family washing, she was seized with agonizing pain in the abdomen, which required for its control the administration of morphine. Vomiting of large quantities of bile-colored fluid began on the following morning, and still recurred. In spite of treatment, the bowels refused to move for more than a week; temperature normal.

On examination, the abdomen was found tympanitic, very sensitive to pressure, and occupied by an immovable, solid tumor, which completely filled the left side from the pelvis to the ribs and extended considerably beyond the middle line; it could easily be touched per vaginam.

The former operation greatly simplified the diagnosis, and left no doubt that the tumor was the enlarged and inflamed spleen. The acute symptoms were attributed to intestinal obstruction, due either to pressure from the spleen or to adhesions at the seat of the ovarian stump. The symptoms grew steadily worse until forty-eight hours after admission, when the bowels responded freely to treatment, after which the vomiting ceased and her general condition improved. The respite was of short duration. The local tenderness, paroxysmal pains, and vomiting returned, accompanied by fever. The temperature ranged from 99° to 101° F. for ten days, and measured 100° F. on the morning of the operation. Peritonitis had evidently supervened, and at a consultation of the hospital staff it was decided that the removal of the offending spleen offered the only chance of recovery.

The operation was performed October 7. The parietal incision, seven and a half inches in length, was made along the outer border of the left rectus. On exploring the spleen, contrary to expectations based on the revelations

of the previous operation, it was found adherent to the abdominal wall, omentum, and intestines. The intestinal adhesions especially were firm and extensive, involving the entire under and inner surfaces of the tumor. Their separation consumed much time, the capsule of the spleen being torn in several places. The peritoneum gave unmistakable evidences of active inflammation. The pedicle was long, twisted through three complete turns, and, with its engorged and tortuous vessels, resembled a huge umbilical cord. It was transfixed, firmly tied with heavy twisted silk, using the Staffordshire knot, and for greater security encircled with another turn of the ligature. The ligature was cut short and the pedicle dropped, a glass drainage-tube placed, and the wound, on account of the patient's condition, hastily closed.

The hemorrhage was slight and easily controlled. The shock was profound and wholly out of proportion to the blood lost or the length of the operation. Hypodermic injections of brandy and strychnine were freely used. Apart from the shock, which threatened to prove fatal for hours after removal to bed, and the temperature, which for twelve days measured from 99° to 101° F., precisely as it had before the operation, there was nothing worthy of special comment during convalescence. At no time was there swelling of the parotid or lymphatic glands. The spleen, drained of its blood, weighed four and a quarter pounds and measured ten inches in length by five and a half in breadth. It was firmer in texture and darker in color than the normal gland. Microscopical examination showed thickening of the trabecular and intercellular connective tissue and pigment in the vessel walls. By an oversight, no microscopical examination of the patient's blood was made before or soon after the operation; at present the proportion of the red and white corpuscles is normal. Seven months after the extirpation, Mrs. A. has grown very fleshy, and reports excellent health, save an overpowering drowsiness.

After a summarizing of the literature on the subject, Zenner concludes that the present position of splenectomy may be briefly epitomized as follows: It is unjustifiable in leucocythæmia or other conditions in which there is extensive involvement of the lymphatic glands or a notable increase in the white blood-corpuscles.

It is indicated in tumors, simple hypertrophies, and other splenic enlargements which have proved rebellious to simple measures and are attended with danger or serious disability.

In movable or displaced spleens requiring

interference, extirpation is preferable to operative fixation.

Severe traumatism of the spleen, with or without an external wound, or simple prolapse of the gland into a parietal wound, demand, as a rule, immediate extirpation. In cases of protrusion, experience shows that excision, partial or total, is a safer procedure than mere replacement.

Removal of the spleen for cystic disease has an excellent record, but most authors advise a preliminary trial of incision with drainage. In abscess it is better, except in rare cases, to incise and drain than to attempt removal of the organ.

#### OSTEOPLASTIC RESECTION OF THE SACRUM.

It is now generally admitted that the only way of dealing effectively with certain ailments of the rectum, especially in its upper parts, is by approaching the seat of disease from the posterior wall of the pelvis. KAMMERER (*Medical Record*, July 28, 1894), with this sentence, begins an able article recording in detail six operations performed by himself, with satisfactory results. He advocates Rydygier's procedure, which is as follows: The soft parts are incised, beginning at the posterior superior spine of the ilium on the left side and running down to the tip of the coccyx, thence in the median line to the anus. After division of the sacro-sciatic ligaments, the soft parts are removed from the anterior surface of the sacrum by the hand of the operator. A transverse incision is then added below the third sacral foramen, and the bone divided along this line with a chisel. A flap is now turned to the right side. With a retractor inserted at the tip of the flap, the latter can be easily held aside and manipulations about the rectum can be as readily carried on as when the bone has been entirely removed. The author has been impressed in all his cases with the rapidity with which this preliminary operation can be done and the absence of profuse hemorrhage. He fully endorses Rydygier's claim that his osteoplastic resection is a much less bloody operation than the permanent removal of coccyx and sacrum by any one of the other methods, with dissection of the soft parts from the posterior surface of the sacrum. In only one instance did Kammerer meet with considerable hemorrhage; here he operated in the lateral position. The knee-elbow position was employed in all the other cases, with distinct elevation of the pelvis, especially of the sacral region, the writer declaring this to be the most

desirable one for rectal surgery, since it controls hemorrhage through elevation, gives excellent access to the field of operation, the surgeon standing between the slightly separated thighs of the patient, also facilitating manipulations with the chisel, the pelvis being supported by sand-bags placed under the anterior iliac spines.

When the flap, including the coccyx, part of the sacrum, and the integuments, can be, from the nature of the case, returned to its place and sutured, the result will be an ideal one as regards restitution of the normal contour of the sacral region. In suturing the transverse incision the author always passes the needle down to the bone, but never includes the bone itself in a suture by any device whatever. Notwithstanding, in several cases in which he has had to elevate the flap a second time, he has always found firm union of bone surfaces, either fibrous or partly osseous. It is unfortunate that secondary operations so frequently become necessary in rectal surgery, for even when we have resected the rectum and made a circular suture of the ends, we frequently find that the latter gives way on the posterior circumference of the bowel. The operation of raising the flap a second time is no more tedious than the first. Greater care must be exercised to avoid the rectum, which now has been drawn close to the anterior surface of the sacrum by cicatricial contraction. When we are dealing with cases, such as fistula, where tamponade of the wound-cavity becomes necessary for some time, we should not suture the flap, but leave the wound-cavity entirely open. The author had good proof of the advisability of this procedure from his fourth case, where he got very good union of the transverse and vertical incisions, but in which a successful tamponade of the deep wound-cavity (about six inches) was not easily effected through the small opening corresponding to the unsutured part of the original incision. To this fact he attributes the ultimate re-establishing of a small vaginal fistula. Such wounds ought to heal from the bottom of the wound-cavity, to avoid even the slightest retention endangering the object in view, and the best guarantee for this is a wide opening, allowing free inspection and tamponade.

Where no sutures are used, some retraction of the flap develops after a time. There is no doubt much less than in flaps that are without a bony substratum. Even when only the lateral incision to the left of the sacrum has remained open, a distinct elevation of the soft parts over the sacrum results from the same cause,—a deformity which can, no doubt, at the proper time, be very readily remedied by an insignifi-

cant plastic operation. This is not so readily accomplished when no suturing at all has been done.

After some time secondary operations on the rectum are even more difficult than the original ones, owing to the development of much cicatricial tissue about the gut, which makes the latter more rigid, and does not, in consequence, permit the approximation of such parts which we may desire to unite by sutures. From all this we may conclude that it will be wise to do secondary operations as soon as the condition of the patient will permit.

The cases of fistula reported have not been entirely cured. They have been much benefited, and one of them is very likely closing. An anterior laparotomy would certainly have been unwise in any of them.

While technically difficult, the sacral route is still the easiest way to get at the seat of disease when the rectum is affected, and also in some cases in which the uterus is to be dealt with. Rydygier's preliminary operation is certainly well devised, and being as simple as the permanent resection of the sacrum, while not disfiguring, assuredly deserves preference.

#### HYPERSECRETION OF THE SWEAT-GLANDS OF THE FEET.

Against sweating feet, LÉGOUX (*Thérapeutische Blätter*, Wien, July, 1894) recommends,—

R. Liquor ferri sesquichlor., 30;  
Glycerini, 10;  
Ol. bergamot, 20. M.

Sig.—Apply with a brush each morning.

#### DANGERS OF GLYCERIN INJECTIONS INTO THE UTERUS FOR THE PURPOSE OF INDUCING PREMATURE LABOR.

EMBDEN (*Medical Record*, July 28, 1894) gives an extract of Pfannenstiël's article concerning the dangers connected with intra-uterine injections of glycerin for the purpose of inducing premature labor, and reports the history of two cases treated by the same writer, as well as one of his own. As a result of the above studies, he concludes that Pelzer's method is liable to occasion indisputable symptoms of glycerin-poisoning. This will be a death-blow to the method.

Concerning the first case, the glycerin cannot be considered the cause of the woman's death, as she suffered from nephritis. It is, nevertheless, remarkable that there was found a small

quantity of blood-colored water in the bladder, the urine being entirely free from blood in the last days before the injection was performed, as shown by frequent examinations. Pfannenstiël tries to find the cause of this in the injected glycerin.

The second case was undoubtedly a case of glycerin-poisoning, and although it did not damage the future health of the woman, it kept her in danger for some time. The woman was in perfect health up to the time of the injection; the urine was normal. One hour afterwards she had symptoms of glycerin-poisoning.

In the author's case there was a woman with nephritis, but there was not noticed at any time before the injection any trace of blood in the urine. After the delivery there was a good quantity of a dark-red urine in the bladder. In examining the same, Embden failed to find any red blood-corpuscles, but there was a large amount of hæmoglobin. The explanation of this appears to be a decomposition of the blood, brought on by the injected glycerin.

This does not seem so very strange, as we know—according to Pfannenstiël—that glycerin is liable to occasion a decomposition of the blood, as has been shown by numerous experimenters with dogs and rabbits, the hæmoglobinuria caused by glycerin bringing on a glomerulo-nephritis, followed, after the injection of more glycerin, by interstitial nephritis as well as by interstitial hepatitis.

It is, of course, strange that neither Pelzer nor others met with a similar accident after injections of glycerin.

Pfannenstiël finds an explanation of this in the fact that Schwan, Lebedeff, and Filehne have shown that in rabbits, when the glycerin is brought under the skin, hæmoglobinuria always occurred, but that it did not occur, or in a slight degree only, when it was injected directly into the veins. Without giving an explanation of this, Pfannenstiël deems it possible that, in Pelzer's cases, the glycerin was very rapidly absorbed by the circulatory system, while in his cases it acted in the decidua uteri as if it had been injected by the hypodermic method.

The writer's case is particularly interesting from the fact of the icterus following the hæmoglobinuria. It seems indisputable that this was caused by the decomposition of the blood poisoned by glycerin. The writer rather leans to the belief that the semi-comatose condition which appeared in his patient was brought on by the same cause; it did not look like a uræmic coma. Another danger of the injec-

tion of concentrated glycerin is the possibility of a thrombosis. Another objection to this method, in common with all injections of fluid of any kind between the uterus and the foetal sac, is the possibility of air entering the circulatory system.

Finally, the writer asserts that Pelzer's method should not be used at all for the purpose of inducing premature labor; more especially is it to be avoided in cases of nephritis.

#### FISTULA OF THE STOMACH IN A CHILD.

A child aged six years swallowed by mistake some hydrochloric acid, following which developed an oesophageal stricture, and gastrotomy was performed. Later gradual dilatation of the oesophagus was practised, and eventually food was introduced by means of a catheter passed through the mouth. At the time he was brought to the service of Dr. CHORON (*La Presse Médicale*, July, 1894) the patient was suffering from marasmus and emaciation threatening his life, and closure of the artificial opening was attempted to stop the continuous outflow of gastric juice and mucus, which was causing an eczematous condition of his entire abdomen.

The stomach was irrigated with a three-per-cent. solution of boric acid. The opening was excised, with a small collar of skin around it. The opening in the abdominal wall was now enlarged towards the left costal border.

With curved scissors the stomach was separated from the abdominal wall. A wound of the liver was tamponed to arrest hemorrhage.

The stomach was sutured with catgut, the other structures with silk (No. 1); first a Lembert suture to the serous membrane, then the muscles and skin received each a separate suture.

#### TREATMENT OF CHRONIC GONORRHEA.

Before the Society of Internal Medicine at Berlin, ROBERT KUTNER (*La Presse Médicale*, July, 1894) demonstrated the advantages of graduated instillations, basing his reasons upon two observations: 1, that gonorrhoea in the chronic form shows itself in circumscribed places; 2, that the introduction of the olive-tipped sound produces more pain at these localities than at other points in the canal.

First, with a *bougie à boule*, he measures the distance of these sensitive spots from the meatus. He then introduces a syringe with a hollow sound adjusted to the point, and applies silver nitrate (one per cent., ten per cent., or twenty

per cent.) or copper sulphate to the spots previously located by his measurements.

The advantages of this method are,—

1. Exact location.
2. Energetic action of the medicine exactly placed.
3. Less reaction.
4. Economy of time.
5. Simplicity of the procedure.

#### TREATMENT FOR ACNE VULGARIS.

PHILIPPSON, in *Therapeutische Monatshefte*, November, 1893 (*Monat. Praktische Dermat.*, July, 1894), says that the causation of acne is still so uncertain that the treatment must be symptomatic.

The pustules are opened and the contents pressed out; then he cuts through the induration; over this a fifty-per-cent. salicylic plaster is laid. Compresses of lead-water and acetic acid soften the skin, cause the pustules to disappear, and relieve the irritation.

For the milder forms, soap, salicylic acid, naphthol, resorcin, and sulphur are recommended.

The following formulæ are used at Lössor's clinic in Berlin:

1. R Naphthol, 10 parts;  
Vaseline,  
Saponis viridis, of each, 20 parts;  
Sulphur præcipitatus, 50 parts.  
M. et fiat pasta.
2. R Camphor trit.,  
Vaseline, of each, 10 parts;  
Pulv. cretæ albæ, 5 parts;  
Saponis viridis, 15 parts;  
Sulphur præcip., 50 parts.  
M. et fiat pasta.
3. R Resorcin,  
Amyli puri, of each, 5 parts;  
Vaseline, 15 parts;  
Zinci oxidi, 5 parts.  
M. et fiat pasta.

These pastes can be applied until inflammation follows, or can be washed off in a quarter to a half-hour, and can be followed by powders.

The first two are best used in the latter manner, while the third is milder. For the mildest forms, where single pustules are found, the following wash is used:

- R Acid. acet. conc.,  
Tinct. benzoës,  
Spirit. camphor., of each, 6 parts;  
Spirit., q. s. ad 100 parts. M.

Sig.—Apply with sponge night and morning.

*PELVIC EXUDATE.*

In a series of papers with the above title, PROFESSOR BIRNBAUM closes with the following therapy (*Der Frauenarzt*, July 7, 1894):

The best prophylaxis is a thorough antiseptic handling of each childbirth, each operation, or other manipulation of the genitalia.

The special treatment is necessarily local, since the fever and constitutional symptoms are dependent upon the local process.

Of prime importance is the removal of irritation or anything causing congestive changes or which obstructs the backward flow of blood, and avoiding unnecessary movements or internal examinations.

So long as fever and pain denote continuance of inflammation, cold compresses, ice-bags, or water of moderate temperature are employed to counteract it.

Kisch recommends for the acute stage intravaginal applications of cold by means of a special irrigator.

For plethoric patients bloodletting is recommended early in the childbirth by applying from six to ten leeches in the inguinal region of the affected side.

Not so strongly recommended is the use of leeches to the vaginal wall, owing to the irritation and the danger of infection.

The ice-bag is used only so long as the pain continues; then water compresses (22° to 25° C.) are resorted to, which may be continued for hours, under which treatment the absorption often goes on to completion.

The much-lauded use of unguent. cinereum, or ointment of potassium iodide, has yielded less prompt results than the water applications.

Where foul-smelling lochia are present, the vagina is washed out many times a day with sublimate (one-tenth per cent.) or carbolic-acid solutions (one to two per cent.).

For the fever, when it is very high and persistent, large doses of cinchona, antipyrin (cautiously), sodium salicylate, digitalis with acid, and the like drugs are employed.

If, in spite of this, the exudate goes to pus-formation, it is still possible to have absorption by the use of compresses. But when the continued high fever denotes the presence of pus, then drainage of the collection is required.

When there is a tendency to point externally, applications of flaxseed poultices, etc., are made.

When fluctuation is detected, an incision is made above Poupert's ligament, from one to two centimetres and two to three centimetres from the anterior superior iliac spine.

When fluctuation is not positive, exploratory puncture is recommended.

From the rectal region it is more difficult to remove the collection, but exploratory puncture may also be tried through the vagina. After opening in this situation, it is well to employ drainage.

When the abscess breaks into the rectum or bladder, without sufficient drainage, Byford recommends inserting a sound through the abscess opening, turning the point against the vaginal wall and cutting against the point of the sound.

If the exudate does not go on to pustulation, then iodine, internally as well as externally, is employed.

Painting with tincture iodi, inunctions of iodine, and potassium iodide ointment, or the rubbing of potassium iodide and lanolin into the abdominal wall.

Painting the cervix and vaginal mucous membranes with the tincture of iodine, or with iodine and glycerin, followed by dusting with iodoform, is also advised.

In anæmic patients the use of iodine must be guarded.

After iodine, cold, lukewarm, or hot irrigations, with or without addition of medications, are recommended.

The use of massage is recommended with caution, suppuration contraindicating this.

Electricity has not proved a success.

Mercury as inunction and internally is used where gonorrhœal cause is suspected.

Naturally, in each case good diet, iron, quinine, wine, and similar tonics must be used, and the patient must not be allowed to leave her bed too early.

---

*THE VAGINAL ANUS AND ITS TREATMENT.*

BUCKMASTER (*New York Medical Journal*, August 11, 1894) gives a carefully condensed report of the literature throwing light on this much vexed subject, with a detailed description of the methods he has employed in overcoming the deformity.

There are so few cured cases that it is easy to explain the attitude of conservative men towards operative procedure. It is important to classify the cases, that we may determine which are fit for operation. It is convenient to divide the cases into two classes. The first class comprises those patients who have control, and the second class includes those patients who pass their fæces involuntarily. The first class is not large in number, and if the patient will take

precautions to preserve cleanliness, and if the opening is large enough to pass formed fæces, operation is not advisable. A douche after each movement will in some cases prove sufficient to keep the patient comfortable. If such precautions are neglected, the mucous membrane of the vagina will become excoriated and abscesses may form in the connective tissue. If, in spite of this advice, the patient should still desire an operation, the results are sufficiently good and the dangers under sufficient control to warrant compliance with her request.

The second class, or those who have no control, includes the great number of cases. Most of them are recognized shortly after birth, and unless the opening is so small that it obstructs the passage of fæces, nothing need be done until a later time. Fæcal matter in healthy young infants is quite unirritating, but as the character of their food changes it may cause great trouble; for this reason careful attention should be given to the diet. It is easier to mould the tissues after the child is fifteen years of age than before this time, but it is not necessary to wait on this account.

In considering the dangers of the operation, we must not forget that all of the fatal cases occurred in a day before antiseptic surgery was understood. The operation the author describes is not more dangerous, he states, than that used to restore a ruptured sphincter. It is used particularly in those cases where there is no control. In cases where the patient has control, and it is necessary to free the bowel for some distance, there is more risk. A number of deaths have been recorded, but with the better technique of to-day the risk is no longer great if the patient be healthy.

The first step in the operation is to introduce a probe into the fistula from the vagina, and bring out the point of this instrument just above the levator ani muscle, the tissue above the probe being divided. The skin should be pierced in front of the lower part of the sling formed by the fibres of the levator ani muscle. The location of this muscle should be ascertained, if possible, before the patient is etherized. When the tissues above the probe have been divided, the rectum is seen, is divided, and may be slightly freed by a few strokes of the knife. It must be remembered that the backward extent of the incision only indicates the backward limit for the plane in which it is found; the skin is divided about an inch farther back.

The next step is to draw the rectum to the skin, and here one is very apt to make a mistake.

The rectum should be fastened to the skin without strain. If proper ligature material be used, and the strain is not too great, the sutures will never cut out, but will become embedded in the tissue, as is the case in all plastic work. On the second day after the writer first operated, he found that the strain had been too much for his stitches, and was obliged to cut those at the sides and place a new one in the middle of the wound; this entirely removed undue tension. If the tension had been too great, he would have drawn the rectum down as far as possible without strain, trusting to a future operation to reach the skin. By careful attention to this caution we can never fail to gain something, and it is only a question of time when the rectum can be securely anchored to the skin. It is important to bear in mind that if union of the rectum to any point of the skin is secured, no matter to how slight an extent, it is not a difficult matter to bring the remainder of the circumference of the bowels in the desired position at a later period.

Having united the rectum to the skin, the raw surfaces left at the side are sewed together. After the completion of the first step, the rectum opens below the vagina, and no raw surfaces are left. The patient can be on her feet in ten days.

The second step of the operation consists in forming that part of the pelvic floor which is usually known as the perineal body. It will differ very much in different cases, as the distance between the abnormal opening and the urethra varies. It cannot be properly done except by an operator who is a good plastic surgeon.

The third step suggests itself on theoretical grounds; the author has not yet had opportunity to put it into practice. He means to split the fibres of the levator ani muscle, as has been done with the rectus muscle in gastrotomy. If this is practicable, we ought to obtain a fairly good sphincter. It is not unlikely that those cases which have gained control after operation have done so by having the muscle, which has been divided, grow about the rectum.

#### FIXATION IN THE TREATMENT OF FRACTURES INTO JOINTS.

In an interesting discussion of this subject by COOK (*International Journal of Surgery*, August, 1894) the following conclusions and rules of treatment are laid down:

1. That bony or serious fibrous ankylosis is the result of injury and subsequent inflammation and not of immobilization.

2. That early passive motion only disarranges the fragments of bone, thereby increasing the production of callus; that it irritates the injured ligaments and, by increasing the inflammation, tends to produce the ankylosis it is thought to prevent.

3. Immobilization is useful only when active inflammation is present, or until the ruptured ligaments and broken bones have thoroughly united.

4. The logical treatment of a fracture into a joint, therefore, should be rest and local applications to reduce inflammation. Reduction of the fracture as early as possible, then immobilization until the bones and ligaments have united (from three to eight weeks, or more, according to circumstances).

5. Passive motion, massage, and use till the tissues become normal, or, if the massage fails, complete rupture of all adhesions under an anæsthetic. The factors which will ultimately determine ankylosis are the nature of the original injury, the character and duration of the subsequent inflammation, the destruction of bone and cartilage, cicatricial contraction of the soft tissues around the joint, and the age and condition of the patient.

#### DANGERS OF THE LONG RECTAL TUBE.

It has long been a disputed question as to whether the long rectal tube can safely be passed into the sigmoid flexure. In this relation the opinion of Mr. HARRISON CRIPPS in a recent number of the *British Medical Journal*, is of interest.

In spite of the condemnation of the long rectal tube by Brodie, Treves, and many other eminent authorities, he still finds that in most cases of obstruction or supposed obstruction the tube has been introduced. Fortunately, these tubes are fairly soft, so that in a capacious rectum, when they impinge and are arrested about opposite the promontory of the sacrum, they simply coil up and do no harm. If stiffer ones are used, the patient's life is placed in imminent risk. A patient at St. Bartholomew's Hospital was to be operated on for ruptured perineum. In order to increase the supposed efficacy of the injection, a quart of soap and water, with some ounces of oil, were injected by means of a long tube; the injection never returned. A few hours afterwards, owing to the acute symptoms, Mr. Cripps assisted one of his colleagues in opening the abdomen. The soap and water and oil were found in the abdominal cavity, and a hole below a reduplicated fold in the upper part of the rectum.

The patient died. He says that the idea that these tubes can be generally passed into and beyond the sigmoid flexure is a pure delusion, save in the rarest circumstances. As a means of diagnosis, or of treatment of stricture beyond the reach of the finger, tubes of any kind are absolutely useless. If a stricture is actually present, it would be 100 to 1 against the long tube or bougie entering it, for it would almost certainly catch in the cul-de-sac generally caused by the invagination of the stricture. If a stricture is not present, the arrest of the bougie by the sacral promontory leads to delusive diagnosis. Brodie, in his lecture, alludes to a case in which a worthy practitioner had spent over one hundred and fifty hours in dilating a supposed stricture situated high up. The treatment had extended over a period of a year. Brodie, who was present at the post-mortem examination, found that there was no sign of a stricture, the bougie becoming arrested by a curve of the sacrum.—*Boston Medical and Surgical Journal*, September 13, 1894.

#### THE TECHNIQUE OF CURETTAGE.

M. SÄNGER (*International Journal of Surgery*, September, 1894) states that, aside from the infectious, gonorrhœal forms of chronic endometritis, the most frequent and important varieties are endometritis, menorrhagia, and hypersecretoria. For the former (endometritis interstitialis, fungosa, climacterica) the best treatment consists in curetting, followed after a few days by the application of caustics. In endometritis hypersecretoria, which is usually limited to the cervix uteri, irrigation, gauze "drainage," and cauterization are especially indicated. Irrigation must be preceded by dilatation of the cervix with laminaria tents, and rarely effects a cure unless associated with other measures. As a preparatory procedure to cauterization, washing out the uterus with a soda solution is of service. The use of gauze tampons, especially of medicated gauze, has a favorable action, although they should not be regarded as promoting drainage. They have the disadvantage of requiring to be frequently renewed. This objection does not apply to cauterization; the stronger the caustic the less frequently it has to be repeated. Säger believes that in general the cauterization resorted to is too mild and too frequently repeated. Among caustics he prefers a fifty-per-cent. solution of chloride of zinc, which is suitable for catarrhal as well as chronic, infectious, and menorrhagic forms. In cases where the cervical canal is narrow, however, in virgins and

nullipara, weaker solutions are in place. If a fifty-per-cent. solution be employed, the application should not be repeated until the end of sixteen to twenty days. For cauterization, Snger employs a long, thin, silver sound.

#### DIAGNOSIS AND TREATMENT OF PROSTATIC ENLARGEMENT.

BELFIELD (*Indian Medical Journal*, August, 1894), in the following sentences, expresses his views on this subject :

While the etiology of prostatic enlargement still remains a matter of speculation, it is certain that the earliest clinical symptoms are due to vascular engorgement of the prostate and, by consequence, of the bladder. The actual increase in the size of the gland should not obscure the other factors in producing the symptoms, which may be out of all proportion to the perceptible enlargement. The factors contributing to the familiar symptoms associated with prostatic enlargement are :

1. Venous congestion and oedema of prostate and bladder.
2. Fibroid thickening of the vesical (prostatic) sphincter, often extending to the detrusor and to the prostate.
3. Suppuration in the prostatic urethra (glands and utricle).
4. Hypertrophy of the prostatic elements (glandular or muscular, or both).
5. Chronic retention of urine, due to any one or all of these four antecedent conditions.

The most important as well as the most difficult task in diagnosis is the differentiation among these various morbid states ; for the prognosis as well as the treatment is determined by the predominance of one or another of them. For example, a prostatic patient complains of frequent and painful urination ; the chief trouble may be an aggravation of the usual venous congestion, in which case a brisk laxative, suppositories of ichthyol, and ergotin and strychnine internally will secure speedy relief. Again, the symptoms may be due to prostatic suppuration, in which event irrigation of the deep urethra with hot water containing hydrastin or silver nitrate is needed ; or the frequent urination may be simply the overflow of a distended bladder, which is relieved by the cautious daily use of a clean catheter.

It should be remembered that the symptoms clinically associated with prostatic hypertrophy depend upon several distinct morbid conditions, of which the mechanical impediment to the exit of urine may be the least ; and that no

routine treatment can be prescribed, the requirements varying with the case.

Our resources for meeting the needs of different patients may be thus summarized :

1. *Medical*.—(a) Improvement in the blood circulation through prostate and bladder is favored by proper diet and exercise, avoidance of constipation, massage of prostate between a sound in the bladder and finger in rectum, and by the daily use of a clean catheter ; internally, ergotin and strychnine are certainly useful.

(b) Suppuration in the bladder neck requires irrigation of the prostatic urethra with hot water, solutions of hydrastin, silver nitrate, etc., in addition to the measures already mentioned.

(c) Induration and distortion of the bladder neck may be improved by dilatation with large sounds or a special dilator.

In a certain percentage of cases the time arrives, sooner or later, when these measures fail to relieve, and more efficient and immediate aid must be rendered.

2. *Surgical Methods*.—(a) The simplest is puncture of the membranous urethra from the perineum and introduction of a drain, which is permitted to remain for a couple of weeks. The subsidence of congestion and oedema, and the cleansing of the bladder thus induced, sometimes makes an apparent cure for many months. Puncture with a trocar through the prostate (Harrison), or drainage of the bas-fond behind the organ, is even more desirable.

(b) By a perineal urethrotomy the surgeon can secure not merely drainage, but also thorough digital stretching of the prostate and the incision or excision of obstructions at the orifice of the bladder.

(c) More satisfactory excision of prostatic obstructions has been accomplished by a combination of suprapubic cystotomy with perineal urethrotomy,—now a standard operation.

Within the past year there have been reported attempts to relieve the sufferings of the prostatic by securing atrophy of the enlarged prostate ; by Bier, through ligation of the internal iliacs, and by Raum,\* through castration. Bier reports three cases ; in one, death from septic peritonitis occurred ; in the remaining two, marked reduction in the size of the gland and decided improvement in symptoms

\* The credit of proposing castration as a means of producing prostatic atrophy undoubtedly belongs to Dr. J. William White, though Raum was probably the first to make a practical application of the proposal on man.—ED.

are reported. Castration alone is said to have accomplished a cure in Raum's two cases.

Two new operations upon the enlarged prostate itself have been recorded; one by Nicoll, who made a submucous removal of the entire prostate from the perineum in two cases with good result; the other, by Belfield, combines the removal of any part or all of the prostate with perfect drainage of the bladder and deep urethra. By incision into the ischio-rectal fossa, the prostate and trigone are laid bare and incised in the median line; each half of the prostate can be enucleated to any desired extent. A suprapubic incision—robbed of its danger by the perfect drainage secured through the posterior wound—can be made, if required for freedom of manipulation. This operation seems to meet all the indications of all cases. Like most other operative procedures, it is undoubtedly too severe for feeble patients to endure.

#### ABSCESS OF THE APPENDIX.

During a recent clinic MCBURNEY (*International Journal of Surgery*, September, 1894) presented a case of more than usual interest and one rarely met with. Three weeks prior to admission the patient had been in good health, when she was seized with a pain in the right iliac fossa, together with nausea and vomiting. The pain continued to increase in severity up to the time she entered the hospital, ten days before. She had a temperature of 101° F., pulse rather feeble, abdomen slightly tender on pressure, but with the walls relaxed. On palpation, a tumor in the right iliac fossa could be readily felt, which was not adherent to its walls, nearly spherical in shape and nodular in character. The history of the case was not of much aid in arriving at a diagnosis. There was no reason to believe that the tubes and ovaries were affected, and although the tumor was situated very near the pelvis, it did not extend into that cavity. There was no distention or obstruction, such as would be caused by a tumor in or around the intestine, thus pointing to the origin of the tumor as an abscess of the appendix.

As the patient was not suffering from high fever, nausea, or distention, the trouble being entirely localized, operation was postponed. The next day the tumor had entirely disappeared, and, unfortunately, no attention had been paid to the character of stools, which might have afforded an explanation of this occurrence. There is no doubt that she had an abscess of the appendix, which evacuated itself into the intestine through a new passage. The

patient was in a more comfortable condition and the pain entirely allayed. Close examination of the abdomen revealed an induration of the tissues at the site of the original tumor. The patient continued to have fever, though somewhat reduced in intensity since that time. Her condition remained about the same. Slight abdominal tenderness, but no distention, was present, and the bowels were active. In cases of this kind, where the abscess has burst into the intestine, some patients have continued in good health and been entirely cured. On the other hand, cases with this history sometimes suffer from repeated recurrences, until an operation has been done for their final cure. In such cases, on cutting down, the reporter has found the appendix entirely separated and lying quite loose in the mass of connective tissue forming the wall of the abscess, the opening in the gut still existing.

Therefore, McBurney advised operation in the above case. He calls attention to the fact that cases of appendicitis differ very greatly in character. Incisions made through the abdominal wall must be adapted to the requirements of each case. In some cases the appendix can be removed with perfect ease through a very small incision, say one and a half inches in length, but to apply such a method, as recently described in some of the journals, indiscriminately to the different cases, and to adopt a standard incision for abdominal section, is useless. The incision must be adapted to the character of the case to be operated on; we should not accept any method of entering the peritoneal cavity through a small opening in operating for an extensive disease. If we know by experience that the disease is small in extent, then we can remove the appendix through a small aperture with advantage. This, of course, does not apply to the cutaneous incision.

The operator, after cutting down to the appendix, found an abscess cavity. The appendix was removed and the opening in the intestine sewed up. The patient was in such a condition that the removal of the diseased appendix seemed the only course to prevent an imminent attack of appendicitis.

#### CÆLIOTOMY IN TYPHOID PERFORATION.

A case of operation of this nature is reported in the *British Medical Journal*, No. 1783. The patient was in the fourth week of the typhoid fever. Symptoms of perforation developed, attended by collapse. The abdomen was opened as soon as the patient reacted. Perforation was

The bismuth is added to prevent irritation of the mucous membrane of the rectum.—*Medical and Surgical Journal*, August 4, 1894.

#### VOMITING OF PREGNANCY.

A writer in the *Lancet* says, "I have not failed once for many years, by a single vesication over the fourth and fifth dorsal vertebræ, to put an end at once to the sickness of pregnancy for the whole remaining period of gestation, no matter at what stage I was consulted. The neuralgic toothache and pruritus pudendi of the puerperal condition yielded as readily, and to one application."—*Medical and Surgical Journal*, August 4, 1894.

#### IVY-POISONING.

A current number of the *Sanitarian* advises the application of Labarraque's (solution of chlorinated sodium) solution in this irritating affection. It should be applied in full strength by means of a pledget of lint or diaper cloth kept constantly wet with the liquid; it will afford relief immediately.

#### SEPTIC OSTEITIS IN CHILDHOOD.

A lecture on this subject was recently delivered by Mr. EDMUND OWEN at the London Hospital for Sick Children, and is reported in the *Lancet* for May 26. Mr. Owen believes that a diagnosis of rheumatism is sometimes erroneously made, when the condition present is, in fact, osteitis due to some septic infection. This may occur without a history of local injury, but usually some illness has seriously disturbed the patient's nutrition. In such circumstances all the tissues of the body are rendered uncommonly susceptible to infection, and it is not strange that the delicate new bone at the end of the diaphysis should suffer. Any septic micro-organisms which have gained entrance into the body might readily implant themselves in this region of slight resistance. Here they would undergo prolific cultivation, secreting their ptomaines to poison the blood and disturb the nervous system. Two cases were presented illustrating this condition. In neither case could a satisfactory cause be discovered. Sometimes the disease is acute and fulminating, and carries the child off before a diagnosis has fairly been made. In others, as in the cases mentioned, it is slow, and simulates articular rheumatism in many respects. Unlike rheumatism, however, the heat, the swelling, the pain,

and the tenderness, although close to the articular area, do not involve it. The tenderness is limited to the region of the bone close below the junction cartilage, and at this point there is a definite thickening. In articular rheumatism the swelling, the fulness, and the redness are confined to the area of the synovial membrane, and there is no thickening about the bone; the results of treatment also aid in diagnosis. The relief of the symptoms of acute rheumatism is, as a rule, so prompt under the use of salicylic acid that an increase in the severity of the articular signs, or even a lack of any improvement after a few days, should arouse suspicion and call for a more thorough and careful investigation. The diagnosis should be made as promptly as possible, for error and delay lead to lamentable results. The treatment is essentially surgical. Incision should not be delayed until the presence of pus is demonstrated. Delay allows the septic inflammation to make irremediable havoc, so that the sooner the area of disease is attacked and cleared out the better. To wait for fluctuation is to give the staphylococci and other micro-organisms full opportunity to do their worst. The incision should be through the periosteum, and, if any pus is here confined, a free opening should be made. The diaphysis should be trephined to give free exit to all septic matter pent up within the bone.—*New York Medical Journal*, August 4, 1894.

#### SPLENECTOMY.

CONKLIN (*Medical Record*, July 28, 1894) reports a successful splenectomy. The patient, Mrs. A., American, aged twenty-nine, married, multipara, was admitted into St. Elizabeth Hospital, May 29, 1893. Her family record is without taint, menstruation normal, and general health but little impaired. Mrs. A.'s early life was passed in a highly malarious district in Southern Illinois, and up to her marriage and removal to Ohio she was subject to frequent attacks of chills and fever, and carried almost constantly an "ague cake" in her side. She had been free from malaria for several years, and, aside from an attack of typhoid fever, has had no serious acute illness. Two years before she began to have abdominal and pelvic pains, and some months later discovered a lump low in the abdomen. Examination disclosed a solid, freely movable tumor, sensitive to touch, in the left iliac region, dipping into the pelvis, but not connected with the uterus, and a small cyst of the right ovary. The uterus was normal in size, but retroverted.

Dr. Jewitt made a coeliotomy June 10, 1893. The solid tumor proved to be a displaced spleen about twice the normal size. It was free from adhesions and easily replaced. The right ovary, containing a cyst the size of a small orange, was removed; left ovary normal; convalescence was uneventful. She was soon discharged, with positive instructions to wear constantly a properly fitting abdominal supporter, with the hope of retaining the spleen in position.

Mrs. A. was readmitted into the hospital during the author's service, September 23, 1893. Shortly after her return home she again began to suffer from pelvic symptoms, and for the past two months had nearly continuous abdominal soreness and several severe paroxysms of pain, which drove her to bed. Her abdomen had been steadily enlarging.

Six days ago, while doing the family washing, she was seized with agonizing pain in the abdomen, which required for its control the administration of morphine. Vomiting of large quantities of bile-colored fluid began on the following morning, and still recurred. In spite of treatment, the bowels refused to move for more than a week; temperature normal.

On examination, the abdomen was found tympanitic, very sensitive to pressure, and occupied by an immovable, solid tumor, which completely filled the left side from the pelvis to the ribs and extended considerably beyond the middle line; it could easily be touched per vaginam.

The former operation greatly simplified the diagnosis, and left no doubt that the tumor was the enlarged and inflamed spleen. The acute symptoms were attributed to intestinal obstruction, due either to pressure from the spleen or to adhesions at the seat of the ovarian stump. The symptoms grew steadily worse until forty-eight hours after admission, when the bowels responded freely to treatment, after which the vomiting ceased and her general condition improved. The respite was of short duration. The local tenderness, paroxysmal pains, and vomiting returned, accompanied by fever. The temperature ranged from 99° to 101° F. for ten days, and measured 100° F. on the morning of the operation. Peritonitis had evidently supervened, and at a consultation of the hospital staff it was decided that the removal of the offending spleen offered the only chance of recovery.

The operation was performed October 7. The parietal incision, seven and a half inches in length, was made along the outer border of the left rectus. On exploring the spleen, contrary to expectations based on the revelations

of the previous operation, it was found adherent to the abdominal wall, omentum, and intestines. The intestinal adhesions especially were firm and extensive, involving the entire under and inner surfaces of the tumor. Their separation consumed much time, the capsule of the spleen being torn in several places. The peritoneum gave unmistakable evidences of active inflammation. The pedicle was long, twisted through three complete turns, and, with its engorged and tortuous vessels, resembled a huge umbilical cord. It was transfixed, firmly tied with heavy twisted silk, using the Staffordshire knot, and for greater security encircled with another turn of the ligature. The ligature was cut short and the pedicle dropped, a glass drainage-tube placed, and the wound, on account of the patient's condition, hastily closed.

The hemorrhage was slight and easily controlled. The shock was profound and wholly out of proportion to the blood lost or the length of the operation. Hypodermic injections of brandy and strychnine were freely used. Apart from the shock, which threatened to prove fatal for hours after removal to bed, and the temperature, which for twelve days measured from 99° to 101° F., precisely as it had before the operation, there was nothing worthy of special comment during convalescence. At no time was there swelling of the parotid or lymphatic glands. The spleen, drained of its blood, weighed four and a quarter pounds and measured ten inches in length by five and a half in breadth. It was firmer in texture and darker in color than the normal gland. Microscopical examination showed thickening of the trabecular and intercellular connective tissue and pigment in the vessel walls. By an oversight, no microscopical examination of the patient's blood was made before or soon after the operation; at present the proportion of the red and white corpuscles is normal. Seven months after the extirpation, Mrs. A. has grown very fleshy, and reports excellent health, save an overpowering drowsiness.

After a summarizing of the literature on the subject, Zenner concludes that the present position of splenectomy may be briefly epitomized as follows: It is unjustifiable in leucocythæmia or other conditions in which there is extensive involvement of the lymphatic glands or a notable increase in the white blood-corpuscles.

It is indicated in tumors, simple hypertrophies, and other splenic enlargements which have proved rebellious to simple measures and are attended with danger or serious disability.

In movable or displaced spleens requiring

least once daily. The nurse should wear a cotton gown, and a cap that completely covers her hair, whether it ornaments her head or not. The discharges from the affected membranes should be received into sanitary cuspidors or old cloths that should be immediately burnt up. In the use of any application directed to the throat, the nurse should stand at one side, or screen herself behind a piece of glass, as do laryngologists in treating a syphilitic throat. She should disinfect her hands after each contact with the patient. The air of the room should be kept moist by steam, so that the secretions cannot dry and, becoming pulverized, float in the air of the room.

Except in epidemics or in hospital practice, the careful physician will not need the protection of gown and hood, as sometimes recommended. In poor practice where proper care cannot be had, he cannot take too great precaution, and should protect himself and his family and his general clientage by every means known to art. He should disinfect all exposed parts of his body, including hair and beard, by thorough washing with sublimate solution, and should not enter any unaffected house before making a complete change of clothing. After the disease is over, or the absence of the Klebs-Loeffler bacillus has been demonstrated by cultures, the patient should be thoroughly disinfected and returned to the family.

For general prophylaxis, all children with a sore throat of any description should be excluded from school and from our houses until they can bring a clean bill of health from a physician of recognized ability. Kissing on the lips should not be allowed, as is so common among children and women. The use of public drinking-vessels should be prohibited. The proper treatment of nasal and pharyngeal catarrhs is an important matter. It is a possibility to inaugurate and keep up an efficient cleansing of the mucous membranes of nose and throat that is so nearly pleasant that a child with a catarrhal inheritance will submit to its daily use as gracefully as he does to the universally employed tooth-wash.

Recognizing the tonsils, including Luschka's, as vestigial structures, which in man subserve no useful purpose, and that an enlarged tonsil is always a source of danger, I unhesitatingly advise their prompt removal in all cases where they are diseased or project into the fauces.

The local treatment has for its objects the destruction or limitation of the growth of the specific pathogenic bacilli and the frequent removal of the poisonous ptomaines produced in process of their rapid development.

This is accomplished by the frequent irrigation of the affected mucous membranes with solutions of agents that are germicidal, but not irritating and not poisonous to the patient, and by the destruction of the pseudo-membrane by digestive substances. In the application of these remedies, it is unanimously conceded by American physicians that any method that forcibly removes the membranes and does damage to the inflamed tissues is to be condemned as worse than useless; for, however active the agent used on the swab may be, the possibility of ptomaine absorption from the denuded and lacerated submucous tissues is so greatly increased as to more than overbalance any benefit that could accrue. Any method of the employment of an antiseptic agent that necessitates a hand-to-hand combat with the child is also to be most heavily condemned, because of the excessive strain thus thrown upon an already weakened heart. More than one child in the last stages of diphtheria has suddenly died in the midst of a struggle with its nurse, and *because* of such struggle. By the aid of a nasal syringe or a good atomizer and an effective remedy that is not disgustingly nauseating, such scenes can be avoided and a large number of patients saved. Personally, I do not consider the choice of a *particular* germicide of the first importance, but hold that a most effective local treatment can be carried out with any of the popular remedies, *provided* the irrigation is thorough and frequent. I much prefer half-hourly irrigation with a solution of boric acid in rose-water, that is accomplished without struggle and with regularity, than less frequent use of remedies more irritating, if not more effective.

Of the substances more recently come into prominence in the local treatment of diphtheria, peroxide of hydrogen stands first. It is a clear, transparent fluid without odor, and has the chemical formula of  $H_2O_2$ . Pure, it is a most violent escharotic, owing to the fact that in the presence of organic matter it is capable of liberating four hundred and seventy-five times its own volume of oxygen. The preparations ordinarily used are the ten- or fifteen-volume solutions,—*i.e.*, solutions capable of liberating ten or fifteen times their own volume of oxygen. There is no question but that it is capable of oxidizing pus and of killing the Klebs-Loeffler bacillus. It has one great disadvantage. In order to hold the extra molecule of oxygen in combination, all makers have been compelled to use nitric acid in the solution. This acidity is manifest in every specimen which I have examined. It is a variable quantity, but suffi-

ciently marked in every specimen to impart to it irritating qualities, not due to the strength of the solution, which, independently of the diphtheritic process, is sufficient, if persistently and frequently used for a day, to cause a thin pseudo-membranous deposit over the mucous surfaces with which it is brought in contact. Dr. Squibb has demonstrated that if this acidity be neutralized, at the moment of its use, by the addition of a little of a ten-per-cent. solution of soda, the efficacy of the peroxide is not diminished, and it can then be used with perfect freedom. This irritating quality of the commercial peroxide of hydrogen has been productive of so much harm that many physicians, including Jacobi, have inveighed against it. I am told that the product sold by a French firm is neutral to test-papers, and should not, therefore, be so injurious; but I cannot speak from personal knowledge. In "pyrozone," a liquid with a trade-mark attachment, the manufacturers claim to have a peroxide of hydrogen made without pressure and without acid, essentially permanent under ordinary conditions. It is sold in ground-glass-stoppered bottles, in three-per cent. solution, for internal use, or in sealed glass tubes, five per cent. or twenty-five per cent., for surgical purposes. The three-per-cent. solution is not neutral, and is quite irritating to my own throat. In using peroxide of hydrogen it is observed that rapid oxidation of the pseudo-membranes and the accompanying secretion takes place, which is indicated by the accumulation of bubbles of gas, and the expectorations are foamy. After an application nearly an hour must elapse before the improved condition can be clearly seen. If the membrane be thin, the fifteen-volume solution can be diluted with ten times its bulk of water, and the solution applied by means of an atomizer; or it can be diluted with fifteen volumes of water and introduced through the nose by a syringe. If the membrane in the fauces is dense, a glass syringe is used and the fine point made to penetrate the membrane, and a few drops of a strong solution is introduced under the membrane. The repetition of this every second hour results in the disintegration of the membrane in a short time.

Carbolic acid in one-per-cent. solution, alone or combined with alkalies and borax, has long been a favorite, and of its usefulness there is little question.

The bichloride of mercury with citric acid, in 1 to 1000 or 1 to 2000 solution, is effective, not disagreeable, and (if not used in concentrated solution) not irritating, and it is not toxic except in those especially susceptible to the

action of mercury. The same can be said of the biniodide of mercury in solution of proper strength, say 1 to 10,000, or even 1 to 20,000. Where children are old enough to gargle and intelligent enough to eject the solution, there is no more effective medication than that afforded by corrosive sublimate or by carbolic acid. In very young children neither should be used, because of the danger from systemic poisoning. At the earnest solicitation of a patient for whom I had prescribed a gargle of permanganate of potassium, I made a personal trial of the solution. I have never prescribed it since, and I am glad to know that it is no longer mentioned as a remedy of power in the treatment of this or any other throat-disease.

Salicylic acid in various solutions has been used, but it offers no superiority to other substances more agreeable.

Boric acid in saturated solution, fifteen grains to the ounce, is capable of greatly modifying the development of the specific bacilli, though it is not so quickly destructive of their energy. Its freedom from odor, from taste, and from colors makes it a favorite remedy with very many physicians. It is so little irritating that it can be used freely through the nose as well as the fauces, and because of this property is especially adapted for use by those who believe in the frequent flooding of the mucous membranes of the nose and fauces as a matter of routine practice. I am quite sure that I have seen far better results by this method of procedure,—injecting a drachm of a four-per-cent. solution of boric acid in rose-water through each nostril every half-hour, day and night,—with the peaceful co-operation of the patient, than I have from the use of other solutions, more powerful but more disagreeable, forced upon an unwilling child.

The vegetable acids—acetic, citric, and malic—are of undoubted service in the treatment of diphtheria. The pineapple contains much malic acid and a peculiar substance claimed to have solvent power on fibrin. However that may be, the use of pineapple syrup or of lemon-juice and sugar, as a vehicle for the medicine to be given internally, will be appreciated by every child, and the selection of Rhine wine as a favorite alcoholic will permit of the addition of vegetable acids as allies in our treatment which are not to be neglected.

Within a comparatively recent period the use of digestive ferments to destroy the diphtheritic membrane has been extensively practised. This use is scientific. The digestion of the membranes does not cure the diphtheria, but it exposes the germs to the action of whatever germicide may be immediately afterwards

used, and, equally important, makes it possible to wash away their deadly product before it becomes absorbed. Pepsin was early used, but because it was less active in alkaline fluids, it was supplanted by trypsin, which, again, has the disadvantage of being active only in an alkaline medium. Either can be used in concentrated solutions or as a glycerole, or the powder can be blown directly upon the membrane. Better than either pepsin or trypsin, because it is equally active in alkaline and acid media, and because its action is augmented rather than destroyed by the ordinary solutions of the various germicides, is the vegetable pepsin extracted from the melon-like fruit of the paw-paw tree. A friend tells me that in Florida, where the native beef is the toughest ever known to man, the Crackers have learned that the meat can be made tender by wrapping it in the leaves of the paw-paw, and the most refractory specimen yields to a night's action of the cut slices of this marvellous melon. I have often demonstrated its solvent powers upon fibrins, and have made use of it in solution with an atomizer, but quickly discovered that a watery solution underwent decomposition very rapidly, and inside of a very few hours developed an odor that rivalled that of some of the so-called pure pepsins. Accordingly I began using it as a powder, blowing it upon the affected surfaces, or sometimes as a thick paste, carefully painting it over the fauces. By recent investigations by Professor Chittenden, M.D., of Yale, it has been definitely established that a solution of papoid can be made permanent by the addition of boric acid or salicylic acid or bichloride of mercury, and that these substances, instead of interfering with the activity of papoid, actually increase its solvent powers, so that an application can be made that is at once solvent and germicidal.

If the diphtheria becomes laryngeal, local medication must then be carried out by means of medicated steam or by volatilized or sublimed drugs. Indeed, it has become habitual with me in every case of diphtheria, except of a very light grade, to order water evaporated in a shallow vessel over an alcohol or oil lamp, so that the air of the room shall be constantly charged with moisture, and to direct that into the water, from time to time, shall be put a tablespoonful of a mixture containing half an ounce each of pure carbolic acid or wood creosote and oil of eucalyptus and six ounces of spirits of turpentine. It seems to me reasonable to think that an atmosphere charged with these volatilized drugs, which are known to be valuable antiseptics and stimulants to the respiratory

mucous membrane, should prevent the invasion of the larynx and trachea. It is in evidence that in cases where it has been early and persistently used complete obstruction has not occurred, and in cases of great malignancy and rapidity, where tracheotomy was early necessary, the constant use of this steam and the occasional spray of lime-water increased the percentage of recoveries. Lime-water is chemically a solvent of the pseudo-membrane; it is also possessed of marked antiseptic properties; it is astringent and very soothing to an irritated mucous membrane. Sprays of finely atomized warm lime-water should be frequently, almost constantly, employed in diphtheritic croup. It does not answer to slake lime for the accomplishment of this purpose, though in an emergency the slaking of stone lime gives large volumes of steam, which of itself is a gain. But steam can be generated so easily by dipping heated irons into water, or by rigging up a steam generator that can communicate with a tent-covered bed, that the crude method of obtaining that result with slaking lime is rarely resorted to.

The sublimation of calomel is highly recommended in laryngeal diphtheria. In a recent discussion to which I had the pleasure of listening, Dr. J. Lewis Smith said that this method had cured cases of laryngeal croup in which it seemed that an operation must be necessary, and he further asserted that O'Dwyer and others of wide experience say that in cases where operations have been necessary, the recovery has been more prompt and more satisfactory under the influence of this drug. The sublimation is accomplished by placing on a tin plate over an alcohol lamp fifteen grains of calomel, and confining the dense white fumes resulting inside of a tent. It is asserted that no case of systemic poisoning has occurred in a patient, though nurse and physician have sometimes become salivated. I have used a modification of this method, and have observed that while the fumes were very irritating to the attendants, the patient was unaffected, and indeed apparently enjoyed the procedure.

To summarize the local treatment that to-day seems the most effective, we would include the early and constant use of steam medicated with the turpentine mixture; the cleansing of the fauces with a solution of papoid, followed by frequent irrigations day and night with bichloride solution or boric acid or Dobell's solution, properly administered through a blunt-pointed nasal syringe; the sublimation of calomel as soon as the larynx shows evidence of invasion the choice of vehicles containing fruit acids in

the administration of medicine, and of a sour wine as an alcoholic. We have no specific for diphtheria.

The indications for the constitutional treatment are three,—*to support the system, to antagonize the ptomaines, and to support the heart.* For the fulfilment of the first indication food is of the first importance, and any medical treatment that interferes with the ability to take and assimilate a full allowance of nutriment is worse than useless. The food should be easy to digest, bland, and for the most part fluid in form; and for this purpose milk and beef-juice answer admirably, though other suitable things may be allowed, like oysters, fresh eggs, oatmeal gruel, and the various invalid foods, especially those partly digested. It should be given every three hours, day and night.

The experience of the past has taught us that in the tincture of the chloride of iron we have a remedy of absolute value, and that the combination with it of chlorate of potassium in small doses enhances its value and does not endanger the kidneys. A mixture containing these agencies in a fruit syrup, like pineapple syrup, is readily taken, and to be effective must be frequently given and in such doses as the general condition of the patient makes necessary. The chlorate of potassium has no specific effect upon the diphtheritic process, but it stimulates the non-infected membrane to healthful activity, and aids materially in preventing the spread of the disease.

The bichloride of mercury in small doses frequently given has been used sufficiently long to have gained a place in the list of effective remedies. It is my practice to give  $\frac{1}{100}$  grain of bichloride of mercury, sufficiently diluted, every half-hour, day and night, and I have yet to see any but beneficial effects from this employment of the drug. It supports the system, stimulates the appetite, and prevents fermentation of food, and has some antiseptic action locally as it is swallowed.

Small doses of quinine are sometimes of use, but, in my experience, the early and persistent use of therapeutic doses of strychnine sulphate or nitrate accomplishes much more; for, while it is a stomachic and stimulates digestion, it is the best possible stimulant to cardiac and respiratory centres, and antagonizes the baneful effects of the ptomaines upon the nervous system as but one other drug in the *materia medica* does.

The use of alcohol is indicated in nearly every case. Under the influence of the ptomaines, it is astonishing what quantities of

alcohol can be exhibited without producing characteristic effects. I hold with those who believe it demonstrated that alcohol, in cases of systemic poisoning, whether from snake-bites or ptomaine saturation, supports the system and antagonizes the alkaloidal poisons more efficiently than any other remedy we have. It should be given early, and unless there be some indications for some other form, the choice should be an old, sound Rhine wine. If the acid of this wine fails to agree with the stomach, a pure whiskey diluted with water should be selected. The dose depends only upon the necessities of the case; and yet it should not be forgotten that it is possible, even in diphtheria, to produce acute alcoholic effects.

If, with these drugs properly administered, the heart shows signs of failure, resort must be had to musk and digitalis. In cases of systemic poisoning, as in typhoid fever or in diphtheria, musk has seemed to me to be more effective than digitalis or any other cardiac stimulant. Indeed, I have come to feel that if musk fails to stimulate the heart where an arrest of the circulation impends in this class of cases, medical art is of no more avail.

The use of pilocarpine has been advocated by eminent authority, but fears of its depressing effects upon the heart seem so well founded that it will be well to wait for others to prove its safety before we advocate its use.

The list of possible remedies is very long, its very length being a proof that we have no specific as yet against a disease that takes more lives annually than does the much-dreaded yellow fever or the cholera.

If time shall prove that in the recent discoveries in the bacteriological laboratories of Berlin a specific has at last been discovered that will not only render our children immune from this disease, if given as a prophylactic, but also cure them safely and quickly when attacked by this dreaded destroyer of life, we can look into the faces of our little ones with a feeling of safety that we do not now know.

Since the preparation of the above, Professor Loeffler's paper on "The Local Treatment of Pharyngeal Diphtheria," read at the last International Medical Congress, has been published in the *Deutsche Medicinische Wochenschrift* for October, 1894.

Recognizing the great advance made in the therapeutics of diphtheria by the discovery of antitoxin, he is still loath to forego the local use of disinfectants for the following reasons: first, because in a very long series of cases the local use of the remedy he has evolved from bacteriologi-

cal and clinical studies has proved of astonishingly great value; secondly, because true diphtheria is so often associated with other complicating pathological processes, the result of pus-producing cocci, none of which are favorably affected by antitoxin, but all of which are destroyed by his remedy; and, thirdly, because the remedy is inexpensive and always at hand.

Briefly stated, the remedy he has arrived at from years of bacteriological and clinical investigations is a combination of disinfectants stronger than any of its components, not at all injurious to the individual, though killing the Klebs-Loeffler bacillus,—the pseudo-bacillus and streptococci in five seconds, and the staphylococci in forty seconds *in situ* in the membranes and the secretions. It produces a sensation of burning, which passes off in a few minutes, and it is not disagreeable in taste or odor.

For the purpose of diminishing the disagreeable sensation at the seat of application, menthol has been added, and the completed formula is as follows:

R Menthol, 10.9 c.c.m.;  
Solve in toluol, 36 c.c.m.;  
Alcohol, absolute, ad 60 c.c.m.;  
Liquor ferri sesquichlorat., 4 c.c.m. M.

Put in a brown glass bottle with a glass stopper.

The solution keeps for months without losing any of its efficacy; its application is simple. The diseased area is to be cleansed of mucus by wiping it with a pledget of absorbent cotton, and then a second pledget saturated with the solution is to be held against the spot for five to ten seconds. The application is to be repeated every three hours in the beginning, and less and less frequently as improvement is noted; and, finally, but once a day, to prevent the redevelopment of the disease from bacilli that may have been deeply lodged in the crypts of an irregular tonsil.

The results obtained in cases seen on the first day of the appearance of the disease have been uniformly and rapidly curative. There has been no extension of the process downward into the larynx or forward into the nose, and convalescence has not been attended by any of the paralyzes.

In cases seen later the results compare favorably with those attained by the use of antitoxin at a similar period.

The effect is shown by a return of the temperature to the normal in from twenty-four to forty-eight hours, and a decrease in the frequency of the pulse, which, however, does not return to the normal standard until about two days after the temperature becomes normal.

The improvement in the general condition is rapid and very marked. The membrane soon becomes changed in consistence, softening and shedding in large flakes in a comparatively short time.

In severe cases the mixture containing the iron solution is always to be chosen, but in cases where the patient is so sensitive as to be unable to bear the transitory smarting of the application, and in cases accompanied by putrefactive processes where the iron becomes changed into the sulphide, discoloring the pharynx and the tongue, and in all of the pseudo-diphtheritic diseases, he recommends that for the iron solution there be substituted two cubic centimetres of meta-cresol or two cubic centimetres of creolin, and the alcohol be increased by the same amount, and asserts that the efficacy of the solution is but little impaired, though it does not exert its influence so deeply.

Since reading this paper I have had but one opportunity to test the remedy. In this case the results tallied exactly with those detailed above.

448 SOUTH SALINA STREET,  
November 13, 1894.

#### A PLEA FOR VENESECTION.

READ BEFORE THE GLOUCESTER COUNTY MEDICAL SOCIETY AT  
A MEETING HELD AT CAPE MAY, N. J., ON JULY 6, 1894.  
PUBLISHED BY REQUEST OF THE SOCIETY.

BY GEORGE C. LAWS, PH.D., M.D., OF PAULSBORO, N. J.

IT is difficult to assign to any one cause the almost entire disuse of venesection. In the early part of this century it was the remedy, and was used indiscriminately. During the great epidemic of typhus fever that prevailed from 1812 to 1820, and for some time after, it was found that the epidemic had impressed some of its characteristics on all diseases, and that depletion was not well borne. The advent of homœopathy, "that remarkable system of doing nothing," demonstrated that it was possible for patients to recover without any medical treatment, except nursing and diet. About this time a reform was originated within the ranks of the profession against the indiscriminate use of cupping, bleeding, and leeching by barbers, unqualified persons, and the laity themselves, as well as in regular practice.

The influence of novelists and writers of from twenty-five to fifty years ago is not to be discounted. From the homœopathic era to the present time it has been the fashion to make sport of medical science and regular practitioners. Thus, among those most widely

read, Lord Lytton, in one of his stories, makes a reformed medical character regret the time when he practised manslaughter; Wilkie Collins demonstrates the superiority of a warm bath over medical treatment in recovering a man from apoplexy; Charles Reade, in almost all of his stories, has for a character the medical crank who sneers at regular practice, cures without medicine, and is vindictively strong against bleeding; George Eliot, in "Middlemarch," demonstrates the beauty of the "expectant treatment of pneumonia by diurnal applications of the clinical thermometer;" the story of the treatment of General Washington in his last sickness has been told over and over again; Dr. Sangrado, in "Gil Blas," with his bloodletting and warm-water diet, has been referred to as though he were a standard medical authority. These will serve as a few examples of the tone of the secular press. Even at the college, when I was a student, it was not unusual for some of the professors to give a sly dig at the practice.

The opposition to bleeding as a remedy came largely from without; what was intended as a reform of abuses within the profession became an almost total abandonment of one of the most powerful and beneficial therapeutic agents at our command. As a routine practice it may have been overdone at times, but its abandonment was uncalled for, and has cost thousands of valuable lives annually.

From reading many of the medical and other publications of a few years ago, we would imbibe the opinion that the people of the last century were habitually bled to the verge of death, and the human race must, in consequence, have been feeble and exsanguineous. The portraits of our grandparents and earlier ancestors show a different state of affairs. Portraits of the Revolutionary worthies in Independence Hall show a remarkably healthy and vigorous set of men; they do not look as though they suffered from organic weaknesses of any kind, or were troubled much with anæmia.

My medical experience began twenty-five years ago; at that time a reaction seemed to be setting in against the antivenesection fad. Professor Stillé advocated its use in his lectures as a powerful therapeutic agent, even recommending it in the early stages of typhoid fever; at the same time I think his list of contraindications had the effect of frightening his pupils; Professor Gross, of the Jefferson College, was also an able advocate of its utility. Dr. Hiram Corson, that thorough, all-around practitioner and typical country doctor,

also urged by tongue and pen the importance of common-sense methods, bleeding included, in treating disease.

Dr. George B. Wood, the author of the "United States Dispensary" and Wood's "Practice," was a firm believer in practical therapeutics, and urged the value of bleeding in inflammation and congestion. While this was the teaching of the time, yet the practical fact remains that from the time I entered the college until my fifth year of practice I was a strong antivenesectionist, and I have a suspicion that other practitioners were for the same reason,—viz., I had never seen a patient bled, and did not know how, except theoretically. I could have performed an amputation with a great deal more confidence. In these early days I encountered some cases of pneumonia and pulmonary congestion, as well as other congestive and inflammatory conditions; the supporting treatment was then in vogue; the human race was considered to be in a weak and tottering condition, requiring nourishing and stimulation when sick. A few cases of accidental hemorrhage occurring with beneficial results led me to a radical change in mode of treatment. My experience with pneumonia, apoplexy, and congestive and inflammatory conditions had not been entirely satisfactory. While most of the cases pulled through, still, there seemed in pneumonia to be impairment of lung-tissue; one or two slipped off easily into a typhoid condition instead of getting well, and a couple of cases that I thought were pneumonia in the outset might as well have been cases of acute phthisis for the deadly certainty with which their lung-tissue softened down.

My experience with a few cases may prove interesting; I select a few from a comparatively large number. These ones I took record of at the time. Almost my first patient from the dispensary was a case of pneumonia. He died promptly before I got in a second visit.

*December 20, 1876.*—W. M., aged forty-eight, farmer, after a drive from the city in a cold rain, was taken with a chill, fever, and all the symptoms of pneumonia of lower lobe of right lung. A laxative of rhubarb and calomel, followed by veratrum viride and gelsemium and quinine and milk-punch and hot poultices, were the orthodox remedies then. He lived some miles out in the country, and on the night of the 21st we had the bad storm of the season. About midnight he had a severe attack of bleeding from the nose. It was impossible to send for me on account of the storm, and as he felt the better for it, he let it bleed.

He saved the blood to show me in the morning; there was over a quart. There was some slight cough, but no pain, and he was able to take a full, deep inspiration; no pneumonia in sight.

The next case was Mabel J., aged twelve. Decided chill February 11, followed by fever and pain at the base of the right lung. February 12, pulse, 135; temperature, 104° F.; respiration, 28. Sharp, painful cough; expectoration raised with difficulty, rusty and bloody. Treatment, a laxative, followed by Norwood's tincture, 3 drops every hour, hot mush poultices to side, and a quieting cough mixture every two hours. February 13, ditto. February 14, had a sharp chill the night before, followed by additional pain in left side; pulse, 155; temperature, 105.5° F.; respiration, 40; cough and expectoration freer, with plenty of rusty sputa. Child delirious. At 10 A.M. I applied three leeches to base of left lung, checking what I considered superfluous bleeding, after leeches dropped off, with Monsel's salt. The leeches gave relief; reapplied the hot poultices, and continued treatment, with the addition of quinine and milk-punch, and went out into the country to a confinement. On my return home, at 8 P.M., found a message to come at once. Found patient very weak, face and lips as white as the pillow, pulse feeble, 80 per minute; temperature, 98° F.; respiration, 14. Found the poultices and the bedding under the child saturated with blood and the leech-bites each running a small stream. Monsel's salt on cotton and a strip of adhesive plaster stopped the bleeding. Wrapped chest in cotton; milk-punch and beef-tea, and quinine sufficient to prevent a return of chill next evening were required, but I do not remember to have seen anything further of the pneumonia. I invested in a lancet.

Christian W., aged twenty-two, a German, a stout, hearty man, had pneumonia of right lung. A physician from the city had seen and prescribed for him while attending another patient in the house. Had been sick three days when I saw him, and was then in a bad way. Temperature, 104.5° F.; pulse, 150; respiration, 38; rusty sputa. Sharp, painful cough, pain in right side, and dyspnoea. Next night, about midnight, was sent for in a hurry and found him much worse; face and extremities dark and livid; pulse small, feeble, and rapid; breathing rapid; patient semi-unconscious and apparently dying. I tied up his arm and bled him; I bled him until the lividity disappeared from the face and the

duskiness from the skin; till his lips and fingernails changed from black to their natural hue; till his pulse slowed down and increased in volume and strength; till he came out of his coma and could take a long, deep inspiration. Subsequent treatment, digitalis, carbonate of ammonium, milk-punch and quinine, and later on an expectorant mixture of squills, senega, and muriate of ammonium, with  $\frac{1}{16}$  to  $\frac{1}{4}$  grain of morphine in each dose. He was convalescent next day.

*August 25, 1878.*—Mrs. M., aged thirty-five, married; three children, youngest thirteen months old; not a robust woman, but still of fair health. The usual history of pneumonia of right lung. Taken sick Wednesday night with chill and fever, pain in side, dyspnoea, dry, painful cough, and later on rusty sputa. Saw her Thursday. Bled her moderately, about twelve ounces. (Her husband and all his family were strong sugarpaths.) Friday considerable better, apparently convalescing; a very warm night and the nurse raised all the windows; towards morning awakened out of sleep with a sharp chill, followed by fever, pain, and distress in left side and return of symptoms in right lung. I saw her Saturday morning. Temperature, 106° F.; pulse, 140 and weak; respiration, 50; face, neck, and extremities livid; cough sharp and distressing; rusty and bloody sputa. At 9 o'clock A.M. I succeeded in bleeding her about four fluid-ounces, with considerable relief. At ten o'clock I tied up the other arm and bled her all I could get,—about two pints that time. I left her about eleven o'clock feeling easy and comfortable and breathing easily. Pulse, 110° F.; temperature, 102; respiration, 20. At 1 P.M. was sent for again in a hurry; she was having considerable uterine flow, and in about an hour miscarried at the second month, with the usual hemorrhagic accompaniment. From all the loss of blood I never saw any bad results or any especial weakness. Uterine discharge kept up about as usual for a few days. We had no more pneumonia.

I remember another bad case of which I have no record, where I failed to draw blood with the lancet until I had applied wet cups to the chest and so relieved the circulation.

I have had numerous cases of pneumonia since, but have had none as bad as those in my early years of practice. In all cases I believe it is good practice to bleed promptly as soon as the disease is recognized. Even a mild case may become dangerous if the usual pathological changes take place in the lungs. I also believe it is never too late to bleed, if the patient

is alive. The amount of relief that follows the first successful touch of the lancet is so great that it has to be seen to be appreciated. It would be a waste of time for me to discuss the clinical history and pathology of pneumonia; with both you are all familiar, and also have adequate libraries for reference. But from the stand-point of an active practitioner there are a few points I would call your attention to: whenever a man dies, he dies either in the heart, the brain, or the lungs. In pneumonia the cause of death is in all three; there is the congested, engorged, and infiltrated lung substance, the exhausted and overloaded heart and venous system, the parotized and congested brain. The blood, which ought to be the very well-spring of life, has become to all intents and purposes a foreign body. There may be such a being as the pneumonia microbe, but he is just as likely to be a *post hoc* as a *propter hoc*. If ever there was a mechanical disease it is this, and common sense points to the means of relief. Blood can be manufactured by the gallon, if required, for future use; but lung-substance may become permanently impaired in a short time, or become the seat of tuberculosis at a later stage.

The heart may have a thrombus formed, to become the immediate cause of death, or may become permanently crippled and weakened. There is but one safe rule with regard to the amount to be taken, and that is, without reference to quantity, to bleed until there is entire relief, if possible, and it is nearly always possible in the early stages. If, for any cause, bleeding is postponed till later, I think it good practice to not check the flow so long as there is improvement, and to stop at the first intimation of approaching faintness, which may always be told by the slight blanching of the lips. Watch the patient's face and pay no attention to the quantity of blood taken; how much a case of pneumonia has to spare no one will believe, except by actual experience. Pneumonia is counted as the sixth disease in fatality. Thousands die every week from diseases classed as pneumonia, pleurisy, congestion of lungs, acute bronchitis, etc., many of which might be promptly relieved if the physician would tie up an arm, tap a vein, and relieve the overcharged lungs, heart, and brain of their superfluity of blood. I have had no experience in bleeding young children, except by leeches; they seem to answer the purpose.

During the late epidemic of gripe a condition prevailed resembling pneumonia and yet seeming to be the exact opposite. There was cough, slight dyspnoea, rusty or rather

plum-juice sputa, lividity of skin, and prostration, this state of affairs coming on slowly in the course of an attack of gripe, and being due to a weak heart and passive venous congestion. These cases yielded readily to stimulants and heart tonics,—whiskey, digitalis, strychnine, etc. In one of these cases, after convalescence, on exposure to cold, there was a sharp, decided chill, fever, and pneumonia of the regular type; patient had had valvular disease for several years, and was seventy years of age. Case ended fatally. I used leeches freely. I believe that in all cases of acute congestion or inflammatory disease the most prompt and efficacious remedy is bloodletting. In case of high fever, try the temperature before and after and be convinced.

In pneumonia do not wait until you find a so-called sthenic case with a strong heart and full, bounding pulse; if you do, you may wait forever; but place your finger on the weak, rapid pulse of pneumonia and observe it slow down and become stronger as the tension is relieved; see the dusky veil lifted from the face as if by magic; see the labored breathing become easy; watch the expression of unspeakable relief that steals over the countenance, and the next time you get a similar case go do it again.

Venesection is the most prompt and efficacious remedy at our command in all the acute inflammatory and congestive diseases; also in apoplexy, threatened and developed, puerperal and uræmic convulsions, for weak and irregular labor-pains in plethoric subjects, in threatened abortion, and as a means of relieving the distress and discomfort of pregnant women, due to plethora and general venous congestion. The operation is perfectly simple, and in the majority of cases you have no doubt of the certainty of the result. I have frequently used it in the above-mentioned diseases and conditions.

In ordinary cases of threatened abortion we often find the happiest results. The following case is extraordinary:

Mrs. W., aged thirty-two; married thirteen years and aborted thirteen times at all periods of gestation, generally between the fourth and the sixth months. Several of the children had been born alive and lived from a few minutes to twenty-four hours. She never went beyond the sixth month. There was no history of syphilis; no means used to cause miscarriage; antisyphilitic and all other treatment, under the best counsel I could get, were of no avail. She could tell forty-eight hours in advance that a miscarriage was going to occur by a feeling

of pain and weight across the loins and by a peculiar prickling and tingling sensation over a surface the size of the hand, which she described as within the womb.

*January 10, 1887.*—Is now three months pregnant. Notified her to send me word as soon as a miscarriage threatened. She sent for me February 6. I bled her freely. Sent for again March 3; bled her again. July 13, delivered her of a healthy child at full term; living now.

In 1890 she became pregnant again. Taken with the usual premonitory symptoms while away from home. July 2, miscarried at the fourth month.

In November, 1891, she became pregnant again. She sent for me and I bled her, at her request, on the following dates: February 8, March 1, April 2, May 4, May 18, June 2, June 24. August 31, delivered her at full term; a healthy child; weighed nine and a half pounds. Now living and healthy. She said that as she either had to be bled or have a miscarriage, she preferred the former.

In conclusion, permit me to quote the great and learned author of the "United States Dispensatory," Dr. George B. Wood. He says it is a fatal lesson to teach the inexperienced that we are to treat inflammation always as a friend and never as an enemy. "My own personal experience with venesection is certainly in its favor. Having been in my early professional life opposed to the excessive use of the lancet, then in vogue, I have no prejudices in favor of the remedy, and yet I can most conscientiously declare that I have almost never had occasion to regret using it in inflammation, but, on the contrary, have had frequent occasion to regret that it had not been used more freely. I know as positively as I can know anything from observation, that it is not only capable of relieving inflammation in the early stages, but will often cut it short and lead to prompt convalescence."

The rule is, I think, universal, that in all cases of inflammation so serious from degree or position as to involve life in danger, bleeding should be employed in the early stages, unless forbidden by general delirium or the low grade of the fever.

My dear medical brethren, these are times of therapeutic pessimism,—

"When schizomicetes grin in glee,  
When microbes dig their holes,  
When germs feel free to split in three  
And exult in their septic souls."

When it is considered the mark of a weak intellect to believe that quinine and the salts

of bark are antiperiodics; that there is any use in an emetic or cathartic; that there is such a thing as an expectorant, a diuretic, or a diaphoretic; when it is an unpardonable medical sin to give calomel to act on the liver; when iodides and bromides are prescribed by inhalation or absorption at the sea-side and iron from a spring in the mountains; when, if you are called to see a case of sickness, it is your first duty to examine the drain and prescribe accordingly for the drain; when great is sanitary science, and doctors who would prefer to be paid by the State, and who do not like the care of sick people, are its prophets; I have felt like lifting my voice and recording my testimony in favor of one of the old remedies and of the old way of using anything in heaven above or the earth beneath to help a sick man get well. That while hygiene and sanitation require part of our attention, still, our main duty will always be the care of the individual sick, the alleviation of suffering, and the saving of individual human lives; and that the neglect of all proper means for these ends, even though those means are not found in the therapeutics of the United States Dispensatory, will do more harm and cause more loss of life that can be saved by all the so-called sanitary science now in vogue.

#### THE PREPARATION OF SURGICAL CATGUT.

A GRADUATING THESIS TO WHICH WAS AWARDED THE DR. L. J. C. KIMMEL PRIZES, June, 1894.

BY ARTHUR WOODWARD BOOTH, M.D.,  
Resident Surgeon Howard Hospital, Philadelphia.

**S**URGICAL catgut, properly prepared for employment as a suture, ligature, or drain, deserves a place in the material equipment of the modern clean surgeon. Its non-use by many and limited use by all can be attributed in most part to its unreliability as regards,—

- (a) Its tensile strength.
- (b) Its freedom from septic infection.
- (c) Its persistence in the tissues as a competent suture or ligature.

Theoretically, we have a twisted animal-tissue cord that is clean, strong, flexible, unirritating, and capable of absorption by the living body tissues.

In actual practice, we find it often septic, weak, yielding, sometimes brittle and totally unfit for surgical purposes.

This thesis is, therefore, written to ascertain if there be any absolutely reliable method of preparation to obviate these imperfections.

*History.*—The history of sutures and ligatures from the earliest times down to the present is an interesting one. Formerly, the universal custom of carrying sharp instruments of defence naturally resulted in a necessity for sewing up the flesh wounds. This may in part explain why the suture was known and used long before the ligature. In reviewing the history of the suture, we find that the early surgeons used them made of silk and vegetable fibre, such as hemp, linen, and cotton. Metallic wire was next employed in conjunction with the above. But not until the nineteenth century was animal tissue introduced, although we find some proof of its occasional employment by Rhazes, 900 A.D., and Albucasis about 1100 A.D.

Till the sixteenth century, the barbaric custom of checking hemorrhage by direct applications of boiling oil or red-hot iron was still in vogue; but in the latter half of this period Ambrose Paré suggested the humane and most natural method,—viz., that of tying the severed blood-vessels. Thus the ligature became known. However, Antyllus, in the fourth century, employed a ligature in his operation for aneurism, and there is evidence to show that the ligature was known by others before Paré, but had been forgotten; so Paré may be said to have rediscovered it. Nevertheless, the hot iron was still used by many as late as 1800 A.D.

Paré made ligatures of vegetable material and silk. It remained for Physick, in 1814, nearly two centuries later, to demonstrate the practical advantages of the animal ligature. He made ligatures of chamois leather, cut in narrow strips and rolled between marble slabs until round and smooth. Dorsey followed Physick's example. Sir Astley Cooper, in 1817, was the first to use violin strings, or "catgut," and through his success it was introduced into practice. Owing to the septic character of these animal ligatures, which were not prepared in accordance with the requirements of modern surgical cleanliness, their use was greatly diminished during the following years, until Sir Joseph Lister, in 1869, *very enthusiastically* advocated the use of the catgut strand, and taught the important lesson that catgut ought to be prepared before being buried in the tissues. His original method consisted of soaking the crude catgut in a five-per-cent. carbolic-glycerin solution. This is essentially his "old preparing liquid," and will be referred to later.

Various other animal tissues have from time to time been suggested and used as ligature material. Among these are kangaroo tendons,

tendon of the dog's tail, tendon of the lepus, or mule-eared rabbit, sinews of the deer and whale, strips of the middle coat of ox aorta, sciatic nerve of the calf, horse-hair, etc.

*Manufacture.*—Why catgut is so named remains unexplainable. It might be suggested that surgeons, at first, used violin strings (and, in fact, some still purchase their supply from violin dealers). It is not unreasonable to believe that ancient string-makers employed the feline intestine. Tradition tells us that the choicest Roman strings came from the lions and tigers of the arena.

The etymology of the word casts some light upon the subject. Catgut is supposed to have been originally "kitgut" or "kitstring,"—"kit" meaning a fiddle may have been confused with "kit" meaning a little cat.

Whatever the reason, the trade name "catgut" has survived, notwithstanding that modern catgut is, in reality, sheepgut.

To one starting out to investigate the process of manufacture there is early manifested an element of taciturnity and even suppression of all-important information, on the part of manufacturers and their agents, as to the exact manner in which catgut is made. It was, therefore, with a great deal of gratitude that the writer accepted the kind invitation of one of the few manufacturers in this country to visit his factory and see the actual operation.

The small intestines of the sheep arrive in barrels from the abattoir in as fresh condition as practicable. They are washed in tubs of water, then passed between rollers; this squeezes out all contents of the intestine with some of the villi of the mucous layer. The intestines are next macerated in a weak aqueous solution of potassium hydrate for several hours, the object being to loosen up the muscular and mucous layers.

The muscular layers with the adhering peritoneum are now scraped off by an ingenious set of rapidly revolving blunt knives.

The same thing is sometimes accomplished by hand by scraping the intestine with a single blunt knife over a flat board. This is customary in Europe.

After all muscular fibres are removed, the process of wringing out between rubber drums, similar to the clothes-wringing process, is carried on until all of the mucous layer is squeezed out. This requires alternate washing in water and wringing; usually three or four times suffice to deprive the intestine of all its coats save the submucous connective tissue.

Notwithstanding the very rough treatment accorded this delicate tissue, it is still intact

as a tube, and may be inflated throughout its entire length.

The next step is to twist and dry these tubes. Some makers use only the half-cylinder of the intestine away from that to which the mesentery is attached. They claim that the outer half contains less fat and blood-vessels, and consequently is stronger in connective tissue.

To this end, they use a double-edged knife inserted in a suitable handle to split the tube into two half-cylinders, the thinner one being saved for fine strings.

The various sizes of catgut depend upon the number of tubes or half-tubes taken together and twisted. The medium sizes contain three or four strands and are prepared in the following manner: The cleaned tubes, still wet from the stripping process, are held together at one end in a clamp, while the other end is attached to a revolving spindle. Twenty to thirty revolutions are given, then the free end is also clamped and the gut allowed to partially dry; it is then subjected to sulphur fumes for half an hour; this twisting and bleaching process is repeated, usually three times or until the gut is sufficiently twisted, after which all unevenness is reduced by rubbing with moist cloth and pumice. It is now removed from the "frame," is coiled in small packages, and wrapped in tissue-paper ready for the market. This is essentially the complete process of manufacture of crude catgut.

Catgut factories belong to the class of disagreeable manufactures called by the French "boyauderie." Early in this century, in France, the attention of medical men and legislative bodies was called to the unhealthfulness produced by the boyauderies, and successful steps were taken to abate the nuisance.

The factories are scattered over Italy, France, and Germany, also a few in Great Britain, and there are two in the United States of America. The quality of the gut is influenced by the climate and by the condition of the animal. Thus, the mild and sunny climate of Italy is preferred to the moisture of England. The old and poorly-nourished sheep (in France sometimes the horse) are better, on account of less fat and more connective-tissue matrix in the intestine. It may be of interest to note that out of this same material other articles are made, as the sausage-casings, textile and silk-mill strings, racket and bowstrings, musical gut string, whip-cord, clock-weight cords, one kind of condom (from the submucosa of the cæcum), and recently, Halstead, of Johns Hopkins Hospital, has introduced a "gut-wool," made by shredding the submucosa with

a tobacco-cutting machine. This gut-wool is used to plug bleeding-points in bone.

In reviewing this conversion from the natural fresh intestine, we are at once impressed by the possibilities of infection and contamination. These, at first, seem unnecessary, and may even offend not only our surgical, but our æsthetic sense of cleanliness. However, from the very nature of the article, it is impossible to treat the intestine from beginning to end in an antiseptic manner. No doubt the early treatment by potassium hydrate immersion and sulphur fumes serves a feeble antiseptic purpose, but is far from complete. And this fact emphasizes the necessity for thorough disinfection of the finished product; for to the above objections must be added the possibilities of anthrax bacilli and spores, or other infectious material, pre-existing in the sheep, also infection from exposure of handling in transport to the surgeon's laboratory.

*Desirable Qualities.*—Absolute sterilization is by far the greatest desideratum! But the gut is well-nigh worthless unless as much care be exercised to render it sufficiently strong, flexible, inelastic to stress, non-irritating, and capable of absorption.

These qualities should be tested with a view to the actual condition under which catgut is placed when applied surgically.

*Histology.*—As has been shown, catgut is derived from the submucous coat of the sheep's small intestine. It is therefore connective tissue. This consists of a matrix of inextensible white wavy fibrillæ cemented into bundles, and associated with these are some curved yellow elastic fibres.

It is this matrix, containing the usual fat, that we must consider in our treatment.

*Chemical and Physical Properties.*—Were catgut as simple in structure and use as gauze, there would be no difficulty in finding an appropriate method of preparation. But, on the contrary, it is a rather complex substance, and before we can rationally discuss disinfectant treatment, the chemical and physical properties should be considered.

*Chemical Properties.*—The substance of which the matrix is composed is collagen ( $C_{100}H_{149}N_{31}O_{86}$ ), a complex albuminoid and probably anhydrous gelatin. So these fibres may be said to be organized collagen or gelatin, and must be treated as such.

It is proved chemically that by hydrating agents, as heating by superheated steam, gastric juice, etc., collagen is converted into peptone-like substances. The practical point to be adduced is that sterilization of catgut by

superheated steam is contraindicated in that the gut tends to turn into a peptone-like substance. This was further proved by an actual test in which the gut was very much softened by exposure to superheated steam.

Also, it might be observed that catgut would readily succumb to gastric juice, and therefore, were that substance present, unless the gut were thoroughly tanned by chromic acid, mercuric chloride, or tannin, it should not be used.

Gelatin (the anhydrous collagen) may be obtained by boiling or long soaking catgut or connective tissue in water.

It is, therefore, impracticable to use water in treating catgut. Collagen is insoluble in alcohol, ether, chloroform, xylol, turpentine, juniper oil, clove oil, etc.

The practical point to be noted is, these agents may be employed to dissolve out fat, or may act as media for disinfectant or storage purposes without injury to the tissue substance.

Collagen is insoluble in oil or glycerin; this suggests sterilized or antiseptized oil and glycerin as suitable storage fluids.

Collagen is altered by tannic acid and mercuric chloride. Chromic acid, alum, etc., produce a tanning effect similar to tannic acid and mercuric chloride. This explains how chromicized gut is not so readily absorbed by the tissues.

By actual test I observed that all astringent chemicals, such as chromic acid, permanganate of potassium, strong carbolic acid, and strong bichloride of mercury, lessen the flexibility, render it brittle and weak. D. Braden Kyle (Philadelphia) in studying effect of fluids upon tensile strength, found that all aqueous solutions weakened catgut by as short immersion as twenty minutes. Alcohol and juniper oil had not this effect. This suggests that catgut may be weakened at the time of operation by placing it in an aqueous solution of an antiseptic, such as bichloride of mercury. Alcoholic sublimate solutions are to be preferred, therefore.

*Physical Properties.*—The natural deposit of fat in the meshes of the matrix is disorganized in the drying and contracting of the gut, and soaks through the tissue, interfering with any chemical treatment, such as with mercuric salts, and prevents thorough saturation of fluids.

It should be dissolved out by ether or xylol at the beginning.

Catgut is hygroscopic and swells up in water, becoming opaque and soft.

Raw catgut swells when immersed in serum; this indicates treatment to prevent this absorptibility, for in practice the ligature, suture, or

drain is in the presence of serum, and, unless proof against any great amount of absorption, the knot will become "slimy" and slip, the suture will yield and cause gaping of wound, the drain will become a plug.

Lister early recognized this unfortunate property, and endeavored to change the character of the gut by chemical treatment. He found that carbolic acid in oil would produce the desired end. If unprepared catgut was soaked in *dry* carbolic acid and oil, the knot would slip when steeped in serum.

"However, if, instead of using carbolic acid in crystallized form, it be first liquefied by water, we secure a proper gut that does not slip."

On the contrary, Lister took some very *old* catgut and found it not necessary to use the aqueous solution of carbolic acid. Therefore, mere age was sufficient. Thus, incidentally, we find scientific evidence of "seasoning."

As with all twisted strands, alternate moistening and drying tends to untwist the gut, with consequent weakening of tensile strength. To avoid this and the snarling, it is suggested that, after having cleaned the gut of its gross dirt by strong soap, it be wound moderately tight about glass cylinders (the ordinary test-tube would do); each coil should have free access to the fluid. (This is impossible when gut is wound tightly on spools.) This procedure is doubly convenient in that it checks untwisting and snarling, and also affords an easy way to handle from one solution to another.

When catgut is knotted its strength is considerably lessened, owing to the brittleness at the point of tension in the knot. This is a very important item, and, to my knowledge, has not been advanced before in discussing tensile strength of catgut.

Nor am I aware of any tests in which the gut was knotted before applying tension, it having been considered sufficient to test in the usual unknotted form.

When ligating or suturing we invariably tie a knot, then strain to tighten it, and often come to grief in so doing. It is obvious, therefore, that catgut should *always* be judged and tested as to its behavior when knotted.

By a series of tests it will be demonstrated that catgut is able to withstand much less strain when knotted than when unknotted.

*Methods of Preparation.*—Since Lister first demonstrated the necessity of special preparation of catgut for surgical purposes, innumerable variations and suggestions have been proposed, but of these few have survived the test of practicability. Some methods have been

too laborious to carry out, but the majority have been advocated with the single purpose in view of antiseptis, totally ignoring the physical and chemical properties of catgut. Many have prepared the gut, and by negative results from test-tube cultures have proclaimed their gut sterile.

Results from culture tests are worthless, unless the gut has been shredded and macerated so as to be certain that each particle of the gut has been explored. And, moreover, unless any antiseptic in it has been neutralized, the culture experiments should be checked by implantation in susceptible animals of specifically infected gut subsequently treated by the method of sterilization in question.

In arriving at clinical evidence of the behavior of catgut in wounds, we should bear in mind that it is an albuminoid substance and an excellent culture material.

Mikulicz (*Klinische Jahrbuch von Güttstadt*, 1889) emphasizes this point and says,—

“Suppuration after the use of catgut is not because the gut is not sterile, but because it is an excellent medium for the growth of micro-organisms. Good results can only be obtained when the disinfection of the wound is absolutely certain.”

To further this claim, I quote Landerer (*Congress der Deutschen Gesellschaft für Chirurgie*, 1889), who gives the following method for the treatment of dry wounds: “The preparation of the patient, instruments, the field of operation, the surrounding skin, the preparation of the hands of the operator, are all carried out after the methods of Kummell and Fürbinger. The instruments are placed in a three-per-cent. carbolic acid solution. After each cut of the knife the wound should be filled with sterilized gauze. Pads of gauze are used in place of sponges, these being sterilized in steam. All bleeding-points are stopped by torsion, when possible. No drainage is to be used. To prevent the formation of cavities, the wound is closed with a Neuber's continuous étage suture. The wound is covered with a compress of gauze and cotton and the whole surrounded with a moderately tight bandage. Catgut is used for sutures, and is sterilized after the method of Von Bergmann and preserved in alcohol.”

Cultures were made from all materials used, but gave negative results. Notwithstanding the treatment, many wounds suppurated, especially when the catgut was used.

All the antiseptic apparatus was examined, but nothing could be found wrong.

No changes have been noticed in the wound

until the sixth day, when silk sutures are removed. On the eighth or tenth day the temperature rises, the edges of the wound are swollen and red, and by separating the edges of the wound, deep suppuration can be seen.

The abscess was almost always found in the deeper parts of the wound where the catgut sutures were used.

The suppuration cannot result from a decomposition of blood, because all bleeding has been stopped.

The preparation of the catgut used in the above operations was as follows: The ordinary red gut was wound around large glass spools, and was placed in a five-per-cent. sublimate alcohol (the latter often changed). When this solution remained clear the gut was placed in absolute alcohol. All the catgut used had been many weeks in alcohol. Small pieces of the gut were placed on the various culture media, with, however, negative results, proving that the infection does not arise from the outside of the gut. As the outside of the catgut is absorbed in the wound the central part of the thread comes in contact with the tissues. This probably explains the fact that the abscess generally develops about the eighth or tenth day. The author then took small threads and separated the fibres of the gut with sterilized needles. The fibres thus prepared were dried for two to three hours in order to allow some evaporation of the fluid in the central part of the gut. These were then placed on the culture media as before, and the result was still negative.

Thinking that the germs might still exist in parts that it was impossible to separate, the gut was softened in bouillon and still no result.

Kummell claims that before the wound can be closed it becomes filled with germs, and these act as the source of primary infection. “Possibly the failure to find germs was due to the fact that the sublimate in the gut was not neutralized by ammonium sulphide.”

Robb and Ghrisky (Johns Hopkins University) have shown that, under the most rigid antiseptic treatment, micro-organisms are constantly found attached to sutures when these are removed from wounds made by the surgeon, and that skin abscess frequently results from presence of the most common of the micro-organisms found in skin, the *staphylococcus epidermis albus*. This is of slight virulence.

The authors conclude, “A wound, at some time of its existence, always contains organisms. They occur in the stitches or in the secretions.

“The number of the bacteria is influenced by the constricting action of the ligature or

drainage-tube, or anything interfering with the circulation in the tissues."

The fact that in their experiments even wire and silkworm-gut sutures were not exempt, but much less infected than the catgut, is of much significance. We have every reason to believe that the micro-organisms of the catgut sutures fed and thrived on the softening catgut, which was impossible in case of wire and silkworm-gut. This evidence certainly ought to lead us to suppose that septic wounds, with well-prepared catgut in proximity, are not due to septic infection from the gut, but to the fact that the micro-organisms find even the most aseptic gut a suitable nidus for growth. This, indeed, is most discouraging; to think that after all our extensive sterilization of the gut we have but succeeded in producing a perfect culture media for any stray bacteria in the wound. This is certainly an indication for infiltrating the gut with some antiseptic that will inhibit the growth of bacteria in it, and at the same time not render it weak and brittle. This infiltration should be made after the raw gut has been thoroughly sterilized. With this in view, I experimented with several antiseptics and obtained the following results:

(a) Bichloride of mercury, in germicidal strength as 1 to 1000, weakens the gut when applied for any length of time, by forming an albuminate of mercury.

(b) Carbolic acid renders the heat-sterilized gut brittle. It is to be observed here that the carbolized gut of the instrument-dealers, which is strong, has never been completely sterilized, but simply immersed in carbolic acid and oil, and, as will be shown later, has been proved septic by bacteriological tests.

(c) The oil of juniper would readily mix with the lymph of the surrounding part, and therefore be of no use for infiltration purposes.

(d) Chromic acid renders the gut brittle, and cannot be used in all tissues; however, it is invaluable for purposes of preserving the gut intact in the body tissues for long periods, and will be referred to under topic of "chromicizing."

(e) The double cyanide of mercury and zinc restrains growths of bacteria and is insoluble in the discharges of the wound. This seemingly answers perfectly; but the salt is almost insoluble in alcohol and only slightly soluble in water, consequently I was unable to infiltrate the gut with it.

(f) Many of the newer antiseptics are unobtainable in the American market, else would have been tried.

(g) Iodoform, although strictly speaking not

an antiseptic, might be used, and can be infiltrated to a slight extent in the gut by soaking it in an ethereal solution of iodoform.

(h) Pyoktanin, or methyl-blue, has antiseptic qualities, is non-poisonous and non-irritating. Sternberg quotes Jaenicke as follows:

Staphylococcus pyogenes aureus re-	
strained by solution of.....	1 to 2,000,000
Bacillus anthrax.....	1 to 1,000,000
Streptococci pyogenes.....	1 to 333,300

In blood-serum stronger solutions are required. Thus, for staphylococcus pyogenes aureus, 1 to 500,000, and a solution of 1 to 1000 killed all of them. Methyl-blue is readily soluble in alcohol and permeates into every fibre of catgut, and does not materially lessen its tensile strength or affect it in any deleterious way. Pyoktanin is not a perfect substance for the purpose at hand, but approaches nearer than any other antiseptic obtainable, and possesses sufficient virtue to be mentioned. The method of preparing the gut with pyoktanin is as follows: The crude gut is deprived of its fat by soaking in ether twenty-four hours. The gut is then sterilized by boiling in absolute alcohol for one hour in a closed jar; then put it in alcoholic solution of pyoktanin 1 to 1000 for twenty-four hours. It may be stored in dry jars or stored in juniper oil. It cannot be stored in alcohol, for the alcohol would in time dissolve out the pyoktanin, and, on the other hand, juniper oil fixes the substance so that it will not stain the hands in using.

*Sterilization.*—The general methods of sterilization are as follows: By heat, either dry or moist; by immersion in germicidal solutions, such as carbolic acid, juniper oil, bichloride of mercury, hydronaphtol, chromic acid. The great objection to simply immersing the gut in these solutions is that we cannot be assured of the sterilization of gut clear to the centre. Juniper oil is not capable of destroying the anthrax spore, and all of the others, if of sufficient strength to destroy anthrax, destroy likewise the strength of the gut. Bichloride of mercury forms an albuminate of mercury pellicle and prevents the thorough saturation of the sublimate.

Braatz (Bruns, *Beiträge zur Klinische Chirurgie*, 1891) sterilizes catgut as follows: The raw gut is allowed to soak for two days in ether and is thus deprived of its fat. The ether is removed once or twice. From ether the gut is placed directly in 1 to 1000 aqueous solution of corrosive sublimate and allowed to remain for twenty-four hours. From the sublimate it is transferred to absolute alcohol and

kept there until used. Or, after soaking in ether, the gut is exposed to dry heat at a temperature of 140° C. for four hours, and afterwards kept in absolute alcohol.

Brunner (Bruns, *Beiträge zur Klinische Chirurgie*, 1891) conducted a large number of experiments in regard to the sterilization of catgut, in which the results obtained by growth on artificial culture media were checked by implantation of the gut into tissues of animals, mostly guinea-pigs. He found that catgut which is infected by the anthrax bacillus could be soaked for six hours in a one-tenth-of-one-per-cent. solution of sublimate, and if the sublimate were neutralized by sulphide of ammonium, that inoculation of the gut into the tissues of animals produced death. If the gut was introduced into the tissues without previous neutralization of the sublimate, no bad results followed, this proving that when the antiseptic remained in contact with the gut it inhibited the growth of germs which had not previously been destroyed. It seems clear that the practical point to be deduced from this is that the gut should be impregnated with some antiseptic. A 1 to 500 sublimate solution seemed to destroy all the germs in the catgut after one or two hours' soaking. The catgut employed in these experiments was not deprived of its fat.

Braatz has shown that when the fat is taken out by ether the sublimate acts much more rapidly and powerfully upon the germs contained in the gut.

As a result of his experiments, Brunner found that after soaking the raw catgut in ether for two days and then in 1 to 1000 sublimate for twelve hours, it could be preserved in a solution of sublimate one-tenth of one per cent., absolute alcohol nine hundred parts, glycerin ten parts, and would be found to be absolutely free from living germs.

Reverdin has shown that when catgut is entirely deprived of its fat and is slowly heated so that the hygroscopic moisture is driven out, the temperature can be carried to 140° C., and it is entirely sterile and sufficiently strong for surgical use.

Brunner, believing that dry heat is less penetrating than when employed through a liquid medium, used xylol, a liquid which boils between 136° and 140° C. He was not successful in preventing growths in culture material by two hours' heating of the xylol to boiling-point. A combined method of first heating for three hours in xylol heated to 100° C. and then soaking for three days in a sublimate-alcohol-glycerin solution rendered the gut absolutely sterile. The xylol is heated by placing the jar

containing it and the catgut in an ordinary steam sterilizer. (Brunner, *Beiträge zur Klinische Chirurgie*, 1890.)

Zweifel prepares the raw catgut by soaking it forty-eight hours in a 1 to 500 aqueous sublimate solution, then for eight days in juniper oil, and afterwards storing it in absolute alcohol.

As to the tensile strength of the catgut prepared by the different methods, all the disinfected catguts were weaker than raw gut. Chromicized catgut and that prepared according to Reverdin's method showed the best tensile strength. This last fact is especially interesting as showing that the raw gut bears a temperature of 140° C. without injury.

Brunner remarks that this high temperature always renders a strand somewhat brittle, and it is to be noted that tests were applied with the gut unknotted. The sublimated catgut by no means came at the end of the list, but was about medium grade so far as strength was concerned. He states that catgut which has lain for three years in 1 to 1000 sublimate alcohol has still satisfactory strength.

The bacteriological examination shows that all raw catgut gives growths in nutrient culture materials.

The sublimate catgut, in three hundred experiments, showed, almost without exception, no cultures. This sublimate catgut was taken directly from the instrument-makers' samples, and not prepared by the surgeon. Even when the gut was taken out of the alcohol-sublimate solution and passed through the non-sterilized fingers and then placed on culture surfaces, no growths developed. And when fresh cultures of pyogenic micro-organisms were rubbed on the surface of the catgut, growths often did not occur. The carbolyzed, chromicized, and juniper catgut all showed growth in a considerable percentage of the experiments. The bacillus which is most commonly found in catgut, which in these experiments was found in the culture material, is, however, not pathogenic.

Reverdin's catgut was found completely germ free. The result of all these experiments on catgut obtained directly from the market showed that sublimated and Reverdin's catgut were sterile, but that the carbolyzed, chromicized, and juniperized catguts frequently contained micro-organisms.

As a result of all his experiments, Brunner concluded that the best methods of preparing catgut is to thoroughly scrub it with a potash soap; then, either directly or after half an hour's soaking in ether, store it for twelve hours in watery sublimate solution 1 to 1000;

then to store it in sublimate one part, absolute alcohol nine hundred parts, glycerin one hundred parts, and immediately before use it should be dipped in watery sublimate solution.

Brunner's final method, published a year later in the same journal, consists in depriving the gut of fat by a two days' soaking in ether, in putting it in a jar which is then filled with xylol and closed (the ordinary preserve jar answers best for this), then heating it for three hours in a steam sterilizer. The xylol is washed out with absolute alcohol and the catgut is preserved in the alcohol-glycerin-sublimate solution already given, and in three days is ready for use.

At the University of Pennsylvania Hospital ligature gut is prepared as follows:

The raw gut is allowed to soak in juniper oil for thirty-six hours, then transferred to absolute alcohol, then wound by sterilized hands on glass spools and put in closed jars of absolute alcohol, and boiled in a steam sterilizer for half an hour; stored in absolute alcohol.

Dr. George R. Fowler, of Brooklyn, has devised an ingenious U-shaped glass tube, each arm being four inches in length. Pieces of gut of ligature length are inserted, the tube filled with alcohol, and ends hermetically sealed. They are then put in a water-bath and boiled for half an hour. Alcohol, under pressure, can be heated to 93.3° C. over the water-bath. These tubes are convenient in private practice. When ligatures are required, the tube is broken by separating the two arms.

When prepared this way, anthrax-infected gut was afterwards sterile.

The late Dr. William Goodell dissolved out fat by commercial ether in twenty-four to forty-eight hours, changed once; gut now immersed for forty-eight hours in 1 to 1000 alcoholic bichloride of mercury, then wound on glass spools and preserved in a mixture of juniper oil two parts, alcohol one part.\*

**Chromicizing.**—The benefits of chromicized catgut in certain cases are well known and appreciated. It, however, is somewhat irritant, and cannot be used in brain and eye surgery. The principle underlying the process of chromicizing is one of tanning, so that the living tissue will not so readily absorb the gut. Care must be taken not to carry the process too far, else the gut will be too brittle for use.

Brunner has shown that chromic acid, of strength taken for chromicizing, does not *per se* sterilize the gut. We are then to infer that the gut must be sterilized by some other means.

Heat affords the best means; but it is to be noted that catgut sterilized by heat does not tolerate chromic acid, carbolic acid, or subli-

mate up to the degree that it would previous to heating.

Professor Doderlin, Leipsic, first soaks the gut in chromic acid solution 1 to 10,000 for ten minutes; then, after evaporating in the air to dryness, sterilizes the gut after Reverdin's method of slowly heating up to 130° C. for two hours. Stores the chromicized and sterilized gut in absolute alcohol.

The method usually pursued in America is: Take a given weight (w.) of dried juniperized gut, put in jar and cover with water, 20 w.; then add carbolic acid, 1 w., and chromic acid,  $\frac{w}{20}$ , and leave to soak for forty-eight to seventy-two hours, according to size of gut. The threads must be free and loose so as to give free access to every portion of gut. Store in alcohol.

Juniperized catgut has been proved bacteriologically not free from micro-organisms.

No doubt the good clinical results from use of this last chromicizing method can be attributed to the facts that the raw gut happened to be exceptionally free from virulent bacteria, and that the central portion of the gut, which probably contained unsterilized material, was not exposed to softening and culture influences until the surrounding tissues had regained their normal power.

**Storage.**—By experiment I found that bichloride of mercury and carbolic acid were unsuitable for storage purposes, but that alcohol or juniper oil was to be preferred.

Sterilized glycerin or olive oil does not materially lessen the strength. The following tabulation shows the relative strengths of the same sample of catgut after having been stored in different solutions.

Method.	Strength in alcohol.	In juniper oil and alcohol.	Alcohol-glycerin sublimate.	1 to 20 carbolic.
	Pounds.	Pounds.		
Brunner.....	18	12	6%	7
Reverdin.....	14	14	6	8
Pyoktanized.....	18	12	4%	5%

**Tests.**—The bacteriological tests of catgut prepared by the various methods have been extensively and successfully carried out by many eminent bacteriologists and surgeons. It is, therefore, not my province to repeat this mode of testing in the hope of either agreeing or disagreeing with them. However, one of the practical tests—that of the tensile strength, *especially when knotted*—has not been fully investigated.

**Methods.**—The methods for testing the tensile strength were as follows:

The tensile strength in all was ascertained on a slow, continuous-strain testing-machine.

- 1. Tensile strength ascertained of raw gut.
- 2. Tensile strength ascertained of raw gut, knotted.
- 3. Tensile strength ascertained of prepared gut.
- 4. Tensile strength ascertained of prepared gut, knotted.
- 5. Tensile strength ascertained of prepared and knotted gut after implantation in the body tissues for different lengths of time.

*Experiment.*—Under antiseptic precautions, pieces of knotted catgut, prepared after Goodell, Reverdin, Brunner, University of Pennsylvania Hospital, Zweifel, pyoktanized, and chromicized methods, were implanted in definite order in the lumbar muscles of a dog. The first implantation was followed by a period of three days, after which the operation was repeated on each of the three succeeding days. The dog was chloroformed twenty-four hours after last implantation, wounds examined, the pieces of catgut removed in reversed order of implantation and carefully arranged according to time and method. Those implanted last, therefore, remained one day. Those implanted first remained for six days. These pieces were then labelled and tested for tensile strength. The results should be considered as relative. The same size raw gut was used in all these experiments. The following tabulations show results:

Tensile Strength Tests.

Method.	Strength un-knotted.	Strength knotted.	Loss when knotted.	Loss when prepared and knotted.

*Conclusions.*—In the surgical preparation of catgut:

- (a) The gross dirt should be quickly removed by potash soap.
- (b) As little water as possible (better if none) should come in contact with the gut.
- (c) The fat should be removed by ether, juniper oil, or xylol, for fat interferes with any subsequent antiseptic treatment.
- (d) The gut will be stronger if, before sterilization, it be wound moderately tight around glass cylinders, such as test-tubes or beakers. Each part of coil should have free exposure to the fluids.
- (e) We can never be absolutely certain that gut is sterile unless heat of germicidal degree has been applied.

A temperature of 140° C. for three hours does not materially lessen its tensile strength. Hence the two absolutely reliable methods of sterilization are: 1. Dry heat slowly carried up to 130° to 140° C. and continued for two or three hours. 2. Boiling in absolute alcohol or xylol, in closed jars, in steam sterilizers, continued for one to two hours.

(f) Storage solution should not contain any antiseptic that weakens the gut, such as bichloride of mercury and carbolic acid. Absolute alcohol and juniper oil are the best solutions for storage. Pyoktanized gut may be stored in juniper oil or dry sealed jars.

(g) Better results are obtained if the gut is taken directly from some antiseptic solution. Hence just before use it should be placed in sublimate alcohol 1 to 1000.

(h) In testing prepared catgut, test cultures should be thorough,—i.e., every particle of gut should be explored, and antiseptics, such as bichloride of mercury, should be neutralized. Cultures should be checked by implantation in susceptible animals.

(i) The tests for tensile strength should be made with knotted gut. By the tabulations, it will be seen that there is considerable loss of strength when the gut is knotted. Thus, the relative brittleness of gut by methods in which heat was used is as follows:

Reverdin the least, then University of Pennsylvania Hospital, Brunner, pyoktanized, and chromicized in their order of brittleness, chromicized being the most so.

(j) That catgut prepared by chromic acid, bichloride of mercury, and pyoktanin is retained longer in tissues, and chromicized longest.

(k) Sterilized gut may be infiltrated with the antiseptic pyoktanin without deleterious effect upon the gut. This infiltration is done

to inhibit micro-organismal growth in the gut itself.

#### POSSIBLE RELATIONSHIP BETWEEN THE TUBERCULAR DIATHESIS AND NITROGENOUS METABOLISM.

VERBAL COMMUNICATION MADE TO THE ACADEMY OF NATURAL SCIENCES OF PHILADELPHIA, NOVEMBER 6, 1894.

BY SAMUEL G. DIXON, M.D.,

Curator in Charge, and Professor of Microscopic Technique and Histology, Academy of Natural Sciences of Philadelphia; Member of the American Philosophical Society, and of the College of Physicians of Philadelphia.

THE present seems to be an auspicious time to review the work that has been already done looking towards the securing of immunity from, and the cure of, tuberculosis, and to suggest the lines along which further success in the quest will be most probable. The task may seem futile to some; to others the frequent announcement of the details of our experiments may be tiresome; but so long as this dread malady or group of maladies remains the scourge of humanity that it now is, and so long as there is evident a single untried method or procedure which offers the least hope of ultimate victory, I feel that there should be no cessation of our efforts, and that periodical reports should be made in order that other co-workers may be aided, and in the hope that the ensuing inquiries and discussions may possibly clear up obscure points or indicate new lines of research.

Therefore I may be pardoned if I briefly review once again the results of my work thus far and the suggestions I have made, especially as they lead up to the announcement of a series of new suggestions, the consideration of which, it seems to me, must be very important in the further pursuit and investigation of this great subject.

When, in the *Medical News* of October 19, 1889, antedating by nine months the discovery of tuberculin by Professor Koch, I reported that I had found a changed form of the tubercle-bacillus, and that I had been able to render certain animals insusceptible, for a time at least, to the dread disease, I believed and still do believe that these discoveries, since happily corroborated by others, were of special importance. For, since that which has been accomplished once can be done again, if I really had produced immunity, though but in the slightest degree, there must be underlying my work a germ or essence of truth which, when once revealed, would make the repetition of that result upon the human being obtainable at will. And, as the bacilli had altered in form without human interference, it was evident that they themselves were in some way able to change the condi-

tions of their environment or to produce something therein or within themselves that was hostile to their normal growth and development.

In this connection I would like to state that, whether the credit be ultimately given to Professor Koch or myself, I feel that the discovery of the active principle of tuberculin was most important, for, though I have not as yet felt justified in using it in experimentation upon human beings, and will not until we have more positive knowledge concerning its precise action upon the economy, it has some value for diagnostic purposes, and also has, by its peculiar action upon tubercular tissues, opened the way to a new field of investigation and discussion.

In the course of my attempts to discover the nature of the active principle of the so-called "tuberculin," I produced from the cultures of the bacilli, including their nidus, a substance that strongly suggested a relationship to the amide group of metabolic products,—viz., glycocin, creatin, creatinin, taurin, tyrosin, uric acid, urea, etc. Realizing that the systems of animals suffering from wasting diseases and with defective excretory organs were in an abnormal condition as regards these products of metabolism, I began at once, with the kindly assistance of Professor W. L. Zuill, M.D., D.V.S., a series of physio-pathological experiments, injecting hypodermically certain members of this amide group, such as urea, creatin, taurin, etc., into both healthy and tuberculous animals.\* The results from this line of clinical experiments by Zuill, reported by the professor and myself in the *Times and Register* of September 26 and October 17, 1891, are remarkable, to say the least, inasmuch as they so closely correspond in many respects to the results from similar experiments with tuberculin. Moreover, I have used similar injections of certain members of this group in the treatment of a marked case of lupus, with a result of very decided improvement and apparently of practical cure, it being now several months since the patient was discharged, and there being no report as yet of any relapse.† Since these experiments were inaugurated by me a substance—thiosinamin—closely similar to urea in formula has also been used abroad with apparent success in the treatment of lupus.

More recently, Professor Vaughan and Dr. McClintock, of the University of Michigan, have shown that certain nucleins are germicidal,

and that there is one of these germicidal nucleins in the serum of the blood.‡ Professor Vaughan has, further, been able to produce by means of yeast nuclein a temporary immunity, at least, to tuberculosis in certain animals, to retard the progress of the disease, and to decrease the virulence of the germ.§ Moreover, hypodermic injections of 40 drops of a two-per-cent. solution of yeast nuclein invariably produced a rise of temperature of from two to four degrees in a patient who had a local tuberculosis.

As to the nature of nucleins, Vaughan states that they are "the chief chemical constituents of the living parts of cells," "the chemical basis of the nucleus of the cell;" "that these nucleins are complex, proteid bodies, consisting of nucleinic acid (which contains a high percentage of phosphorus), in combination with highly complex basic substances; that the nucleinic acid of all nucleins is probably constant, but that the basic substance differs in the respective nucleins;" that these "basic substances yield as decomposition products one or more of the so-called xanthin bodies,—adenin, guanin, sarkin, and xanthin;" and, finally, that the nucleins are "insoluble in dilute acids, soluble in dilute alkalies, and that they resist peptic digestion, by which means they may be separated from most other proteid bodies."

Now, there must be apparent to every one the close relationship existing between the amide group of metabolic products to which I have referred and the nucleins, and possibly tuberculin, especially as we may infer from Vaughan's statements that the active principle of the tubercle-bacillus cell (tuberculin?) is a nuclein, as the nuclein bases yield xanthin bodies which are closely related to uric acid and the above-mentioned amide group,|| and as "Horbaczewski has ascertained that uric acid is produced from the nuclein of spleen pulp, which contains the antecedent or mother substance of uric acid, this mother substance yielding not only uric acid, but the other xanthin substances."¶ Is it any wonder that the clinical results from the introduction of these bodies into tuberculous subjects are so remarkably similar in character?

The question that naturally first arises in the

† *Ibid.*, February 21, 1893.

mind of the investigator is, What is the real nature of tubercular inflammation and of the peculiar action or reaction of the above substances upon tubercular tissues and tuberculous subjects?

I have already stated that I believed that where the lithæmic and tubercular diatheses or conditions were present at the same time in any individual, it was an exception to the rule, and have suggested that it might possibly be advisable to endeavor to produce, by hypodermic injections of certain members of this amide group of metabolic products or otherwise, a temporary condition of gout or lithæmia in our tuberculous subjects, hoping thereby to possibly supply that in which the pathological tissues are deficient or to alter the inflammatory condition of the tissues either in kind or degree,—to change the soil, as it were,—so that either the hostile pathogen could no longer find in those tissues a suitable nidus, habitat, or environment, or that the vital activities and resisting agencies of the body would be increased and strengthened sufficiently to overcome the disease germ before it could multiply and produce its harmful effects in the body.\*

To strengthen this suggestion, I need only remind you that the lithæmic condition is one assumed by general consent to be in some way due to or connected with excessive assimilation and metabolism of proteid substances, together with increased oxygenation; while the tuberculous diathesis is manifestly one dependent upon deficient proteid assimilation and decreased oxygenation. Are we not all familiar with the fact that those predisposed to tuberculosis generally resist the disease as long as they can maintain growth or while their metabolic activities furnish *more* than enough pabulum for mere sustenance, and that as soon as that excess of assimilation ceases, tuberculosis develops and eventually overcomes the subject?

I would also like to call your attention to the fact that, so far as I know, no one has attempted to explain the cause or rationale of the noted reactions of tuberculin, nucleins, and the members of the amide group mentioned upon tubercular tissues and tuberculous subjects; but that there is some rational and reasonable connection between these reactions and the facts of the foregoing statements must be patent to

every one. If not, these additional remarks concerning the experiments of Horbaczewski, which I quote from Professor Vaughan's article, may serve to emphasize the argument.

"The mother substance from spleen nuclein yields not only uric acid, but the other xanthin substances, as xanthin, sarkin, guanin, and adenin. Uric acid is formed when the antecedent or mother substance is split up in the presence of an oxidizing agent, while the other substances result when the process is carried out in the absence of such agents. This is in complete harmony with the facts which have been ascertained by the conversion of one of these xanthin bodies into other members of the same group. Certain other nucleins as well as that of the spleen serve as antecedents to uric acid. This discovery makes clear a hitherto most perplexing problem which has concerned the chemist, the physiologist, and the clinician. In short, it explains the origin of uric acid in the mammalian body. The chemist had taught us to look upon uric acid as the result of imperfect oxidation, the completed product of which is urea; but the physiologist has been unable to demonstrate this supposed relationship between urea and uric acid. The experiments of Horbaczewski show that the amount of uric acid and other xanthin bodies formed is a measure of nuclein metabolism; in other words, it indicates the number of cells which are suffering disintegration processes. Normally, the white blood-corpuscles constitute the most important and probably the most numerous nucleated cells daily undergoing destructive changes. Therefore any condition which induces an abnormal leucocytosis increases the amount of uric acid. In infants the number of nucleated cells is proportionately larger than in adults and the amount of uric acid formed is correspondingly larger. In the fasting state the white blood-corpuscles are reduced and the uric acid is also diminished. Meat diet increases the number of white corpuscles and consequently the formation of uric acid. Quinine and atropine diminish the number of these corpuscles, and by so doing lessen the amount of uric acid formed; while pilocarpine, antifebrin, and antipyrin have been found to increase both. The increased formation of uric acid and xanthin in leukæmia, phosphorus-poisoning, acute febrile diseases, especially pneumonia, cirrhosis of the liver, and pernicious anæmia now finds an explanation."

I might go further and show how glycosin, leucin, tyrosin, urea, etc., are closely related to the fatty acid series, the amidogen radicle

\* *Medical and Surgical Reporter*, September 6, 1890; "Proceedings of Academy of Natural Sciences," November 18, 1890, and February 21, 1893; *Medical Bulletin*, May, 1893.

NH<sub>2</sub>, taking the place of H in a hydrocarbon radicle, or a hydrocarbon radicle replacing H in the amidogen radicle,\* at the same time recalling to your attention the fact that the abundant administration of fat is essential in the treatment of tuberculosis, and that I have secured some apparently good results by the injection of glycerin, which not only readily combines with the various fatty acids to form fats, but has a decided influence upon the metabolic activity of the liver. Or I might mention that recent investigations seem to indicate that the efficacy of cod-liver oil as a reconstructive in these wasting diseases largely, if not altogether, depends upon its contained alkaloids, three of which have a direct connection with urea in construction and formula, and the others evidently being closely related to a combination of the amidogen with the glycerin radicle.

However, I think that sufficient has been said to open up the very broad question as to whether the conditions that predispose to or favor the development of tuberculosis are not those of faulty, deficient, or abnormal nitrogenous metabolism, and whether the truly scientific method of obtaining immunity against this dread malady will not necessarily come through a thorough understanding of the processes involved and the changes that take place in the various cells and tissues of the body, in so far as they are related to the assimilation, secretion, and excretion of nitrogen and nitrogenous compounds.

Believing that this is largely so, I would, therefore, suggest that future work carried on along the following lines promises to return good results and to lead to substantial ground on which we may base our hopes of eventually securing positive immunity. Such work should include, I think,—

1. A systematic investigation as to the amount of nitrogen secreted by the healthy, the tuberculous, and the lithæmic, and the relative proportion of the various nitrogenous products in each case.

2. A tabulation of the clinical results from the systematic *hypodermic* administration of tuberculin, nucleins, and members of the amide group of metabolic products to healthy, tuberculous, and lithæmic subjects, preferably the same, if possible, as those in the first series of experiments; the results to include full reports as to temperature, secretion and excretion of nitrogen and nitrogen compounds, increase or decrease in white blood-corpuscles,

condition of subject, etc. Considerable of this work has been done, but far more is needed. Collateral experiments upon animals would also have their place here and would be of value.

3. Experimentation as to special treatment or diets as would be indicated by a study of the results of the above series of experiments.

Confident that such a work as indicated will be rich in returns to those who undertake it, and trusting that others may be induced by these remarks to join with me in carrying it out, either in general or in detail, I am sure that in whatever way immunity against tuberculosis is eventually secured, it will be, in very truth, a blessing to humanity whose magnitude is almost inconceivable, and which will be measured least of all by the undying fame of its discoverers.

*AMPUTATION OF BOTH LEGS AT THE  
KNEE-JOINT FOR PARALYTIC CLUB-  
FOOT IN A CASE OF SPINA BIFIDA  
AND COMPLICATED BY CON-  
GENITAL INGUINAL  
HERNIA,*

IN WHICH THE TESTIS AND APPENDIX VERMIFORMIS WERE REMOVED DURING  
AN OPERATION FOR ITS  
RADICAL CURE.

READ BY TITLE AT THE MEETING OF THE AMERICAN ORTHOPÆDIC ASSOCIATION, WASHINGTON, 1894.

BY WILLIAM J. TAYLOR, M.D., PHILADELPHIA, PA.,  
Professor of Orthopædic Surgery in the Philadelphia Polyclinic  
and College for Graduates in Medicine; Attending Surgeon  
to St. Agnes's Hospital; Assistant Surgeon to the  
Orthopædic Hospital and Infirmary for  
Nervous Diseases.

**A**MPUTATION at the knee-joints of both lower extremities for congenital paralytic club-foot is seldom found to be necessary as an orthopædic measure, for conservative methods of treatment by means of braces and, if need be, tenotomy, with some one or more of the operations upon the tarsal bones, usually accomplish good and lasting results. Occasionally, however, the deformity is of such a character, and the resulting disability is so great, that no form of appliance or conservative operative procedure will give the desired results. Under these conditions, amputation, followed by properly fitting and accurately adjusted artificial limbs, is our only means of positively benefiting the patient, and the more radical procedure is, therefore, the one to be selected.

A detailed account of one case where this

\* Waller's "Human Physiology."

mode of treatment was carried out with the happiest results will, I trust, prove of interest.

This little patient, a boy aged six years, was admitted into the Orthopædic Hospital and Infirmary for Nervous Diseases, under the care of Dr. W. W. Keen, and it is through his kindness that I am able to make this report.

As assistant surgeon to the hospital, I have been enabled to assist Dr. Keen in the performance of all of the operative procedures here described, and much of the subsequent care and treatment has been intrusted to me.

I have nowhere been able to find recorded an instance of similar deformities, and the remarkable number of serious surgical operations which this patient has passed through in perfect safety and with comparatively little shock and suffering marks his case as unique.

His father, mother, three sisters, and one brother are all living and in good health, and there have been no other cases of deformity in the family. He is the third child born to the mother, and during pregnancy she remembers having had a severe fall, and suffered a great deal of pain during the remainder of the time she was carrying him. Labor was normal, but very painful, and the boy was born with the deformities about to be described. He has always been well, with the exception of an attack of chicken-pox and one of la grippe. All parts of the body, with the exception of the lower limbs, developed as in other children, and he began to crawl at about the average age. His mind developed as rapidly as in the case of the other children. He is a well-nourished child; all the organs are in good condition, except, however, incontinence of urine and fæces. The head, chest, and upper extremities are normally developed. The laminae and spines of two of the lumbar vertebrae are absent, and there is a small, soft tumor over this site,—a spina bifida.

He has also a complete congenital inguinal hernia on the right side.

The right hip is normal in size and shape; the right femur is normal at the hip-joint, but gradually tapers towards the lower end to a mere blunt point, with an absence of the condyles. The muscles of the thigh are poorly developed, especially towards the knee-joint. There are two bony knobs on the inner side, about the middle third of the thigh; these were thought not connected with the femur, and the skin moves freely over them. The patella is absent. The tibia is dislocated backward and upward upon the femur. It may be completely flexed, but can only be extended to a right angle. The fibula is absent, and the

muscles of the leg are much wasted. At the ankle-joint there is a dislocation backward and upward. The foot is inverted and the toes point inward. The great toe is absent. The pulse in the dorsalis pedis is easily distinguished.

The left hip-joint is normal, and the femur is normal to its lower third, where it bifurcates, and there is a knob of bone projecting down and inward. The external portion takes the course of the natural bone to form the knee-joint. The condyles are very small and the patella absent. The knee is dislocated backward and upward, and is flexed, making an angle of about sixty degrees when fully extended. There is a small fibula which turns around the tibia until it comes in front of it at the ankle, the external malleolus being in front. The foot is in extreme talipes varus, the toes pointing inward, while the sole of the foot is turned upward. The left leg is a little larger than the right, and there is slight motion in the left knee-joint. The ankle-joints have no motion on either side, while the motion at the hips is almost perfect. Sensation in both limbs is good, and the electrical conditions of the muscles are normal. (See Fig. 1.)

His manner of moving from place to place is to sit upright upon the floor with all parts of the lower extremities flexed. He then leans his body forward and places his hands upon the floor as far as he can reach, and brings his body up to his hands. In fact, he swings his body, using his arms as one would a pair of crutches.

As his legs and feet were perfectly useless appendages, with no possible hope of their ever becoming serviceable, either with the aid of appliances or by operative measures, it was decided, after very careful consultation, to remove them by amputation and apply in their stead accurately fitting artificial limbs.

It was at first thought that amputation in the middle of the legs would be best, as being the most favorable point for the fitting of artificial limbs; the internal knob of bone, or bifurcation of the femur, and the pieces of bone on the right thigh to be removed at the same time, as they would interfere with the adjustment of the artificial limbs. It was deemed best to operate in instalments, and to permit the patient to recover thoroughly from one operation before attempting another. Accordingly, the first operation was performed January 4, 1893. An incision was made over the knob of bone which projected from the inner side of the left femur, and the skin and fascia dissected off. This was found to be a

pear-shaped piece of bone, projecting from the femur about three inches above the knee, on the inner side, and united to it by bony union. This projection of bone was three and one-eighth inches long by one and one-sixteenth inches in diameter. The portion which was attached to the femur was about three-quarters of an inch in diameter and narrowed to form a neck; a small bursa covered the tip of this prominence. This was removed by sawing through the neck and smoothing the ends with cutting forceps. The artery passed behind this knob of bone and was exposed in the incision, but was not wounded. In view of the character of the tissues, it was found impossible to amputate through the leg as at first proposed. An incision was therefore made over what would ordinarily be the external condyle of the femur, down and around the front of the tibia and up to the inner condyle. This flap was dissected back, the tibia disarticulated at the knee, and a smaller posterior flap cut from the skin. The wound was dressed with sterilized gauze, while a small piece of gauze was introduced between the lips of the wound, for drainage. This wound healed without special incident other than a considerable discharge of serum, which came apparently from a portion of the synovial membrane of the bursa which had not been thoroughly removed at the time of operation.

On March 3, 1893, the stump of the left leg having thoroughly healed and being in perfectly healthy condition, the right leg was amputated at the knee-joint by a similar incision to that used at the former operation. Two knobs of bone about three-quarters of an inch in diameter were found on the inner and middle third of the thigh. The incision was enlarged from its inner angle, and these projections of bone removed by a chisel and rongeur forceps. They were found to be connected with the femur by ligamentous attachments only, and the abductor magnus muscle was attached to them. They were removed with great difficulty, and in so doing the deep femoral artery was cut, as it lay immediately in contact with them. This was, however, easily ligated, and the amount of blood lost was small. A drainage-tube was inserted, and the wound closed and dressed with aseptic gauze. He made a perfect recovery, with no ill effects whatever, from these two severe operations.

It was found impossible to reduce completely the hernia and to apply any sort of truss which did not give pain by its pressure. As artificial limbs were to be worn, a further appliance in

the shape of a truss encircling the waist was not to be thought of. Therefore, on May 24, 1893, after thorough preparation of the parts, Dr. Keen operated upon the hernia, his intention being to use Halsted's modification of Bassini's method. An incision was made four inches long, parallel to and three inches above Poupart's ligament, and the sac opened. Several organs were found in the sac,—the appendix vermiformis, bowel, testicle, and cord. The appendix was three and one-eighth inches long. It was ligated with silk and the lumen of the stump disinfected with pure carbolic acid. The stump was then invaginated and covered by bringing the serous surfaces of the bowel together over it. The testicle was then removed, as it was much atrophied and adherent to the sac, and the sac torn loose and sewed together, the excess of the sac having first been cut off. The appendix, when removed, was much longer than normal, and was attached at its tip to the wall of the hernial sac. When examining it after its removal, a small piece of tough vegetable material was squeezed out of its interior. This appeared to be a small bit of apple skin, but there were no evidences of inflammatory mischief to its lining mucous membrane. The pillars of the ring were sutured, and, lastly, the skin. A gauze and iodoform collodion dressing, thoroughly sealing the wound, was applied, with an ample covering of gauze dressing. An inverted Y-shaped splint was then applied to the spine, extending downward; to this both thighs were firmly bandaged, to prevent all movement and enable the wound in the loin to close by primary union. From this operation also he recovered without a bad symptom. There was very little shock, from which he rapidly reacted, and his convalescence has been perfect.

From all of these serious and necessarily prolonged operations his rapid recovery was truly remarkable. At no time was his condition such as to cause any alarm, and his temperature chart showed a most gratifying absence of fever. He was perfectly calm and cool throughout, never crying when taken to the operating-room, or manifesting that fear so common to all children, as, indeed, to most adults.

On July 13, 1893, artificial legs were fitted, and by July 25, by a little careful adjustment, he was able to walk around the ward by the aid of a chair which he pushed in front of him, and in a short time with the aid of crutches, and then a cane.

He can now walk alone and without the aid

of crutch or cane, although as a measure of precaution, in moving about upon our polished floors in the hospital, he uses one crutch for security.

These cuts are from photographs taken in part by me and in part by Dr. Boyer, the resident surgeon.

Fig. 1 was taken while he was lying upon his back in bed, as it was impossible to extend the legs farther than a right angle.

Fig. 2 shows the condition of the legs and feet after their removal.

Fig. 3 shows the condition of the stumps after complete recovery from the amputations, with the scars made in the removal of the projections of bones. It also shows very accurately the hernia.

Fig. 4 shows the application of the artificial limbs, which were only made after the most careful and painstaking adjustment by Mr. Osborne, their maker. As will be seen, it was necessary to bring the knee-joint much farther forward than is usual, to compensate for the want of complete control of some of the muscles of the thigh and to enable him to balance perfectly. Elastic running down the shin-bones (?) was necessary to provide sufficient resistance to permit of the extension of the legs in walking.

Fig. 5 shows the three bony projections removed, as well as the atrophied testicle and the enlarged and thickened appendix vermiformis.

#### THE INFLUENCE OF ATROPINE UPON RESPIRATORY VOLUME.

DR. ALFRED LEVISON (*Berliner Klinische Wochenschrift*, September 24, 1894) declares that the effect of atropine upon respiration is to make it hurried, to increase its size, and to make it spasmodic. Morphine opposes this action. He quotes at some length and with approval the paper by Wood and Cerna on morphine and chloral as respiratory depressants, and atropine, strychnine, and cocaine as respiratory stimulants. Three points, he thinks, need further study:

1. How is the respiratory volume affected when small doses of atropine are brought directly in contact with the respiratory centre?

2. How is the respiration affected when morphine and atropine pass simultaneously into the blood?

3. How is the respiratory volume affected after the administration of atropine when the vagi are cut?

Vollmer has already referred to the first point, and Levison has confirmed his results by injecting atropine into the carotid. There was a marked and immediate increase of the respiratory volume depressed by morphine. This increase was not maintained at its greatest height, but remained always and for the most part considerably above the point at which it was when the atropine was administered. A primary fall, such as is observed when atropine is injected under the skin, was never observed; hence it is assumed that such a fall is due to an action upon the peripheral endings of the vagus in the lungs,—a partial paralysis, which is more than compensated a few minutes subsequently by a central action.

2. Two rabbits of the same litter and about equal weight received, the one morphine alone, the other morphine and atropine. The stronger rabbit received .02 morphine, the weaker .02 morphine and .04 atropine in a vein; proportionately, therefore, more morphine than atropine. In one and a half hours the respiratory volume in the animal which received only morphine had reached only a third of the initial, whereas in the other animal, which received morphine and atropine, the initial number was already reached. Therefore there is here again a clear proof of the antagonism of both alkaloids, when atropine is not given in absolutely poisonous dose.

3. After section of one vagus, the respiratory volume depressed by morphine was raised, but depressed after section of the other vagus. If now, as in both the first experiments, the atropine be injected into a vein, spasmodic respiration, from the intense irritation of the atropine upon the respiratory centre, appears, and the respiratory volume sinks for a moment, but quickly rises again.

Levison maintains:

1. There results from experiments on animals the possibility that atropine in moderate doses is of value in morphine-poisoning in men, the respiration being raised in frequency.

2. This rise is the result of an irritation of the central organ in the brain.

3. The improvement of the heart's activity through atropine is likewise of therapeutic significance.

4. The exciting action even of moderate doses of atropine can easily become paralyzing if it passes directly into the blood.

Levison concludes his paper by referring to reported cases in which atropine had been of service in opium-poisoning.

### THE TREATMENT OF APPENDICITIS.

AT a recent meeting of the College of Physi-  
cians of Philadelphia, Dr. John B. Deaver  
read a paper upon "The Treatment of Appen-  
dicitis," in which he reported a large number  
of operations with a great number of recov-  
eries.

In the discussion which followed, and which  
was opened by Dr. McBurney, of New York,  
views were expressed which cannot fail to have  
an influence in the treatment of this disease  
hereafter.

Dr. Deaver took the rather advanced stand  
that practically every case of prolonged acute  
pain in the right iliac fossa was appendicular  
in origin, indicated the presence of an appen-  
dicitis more or less acute, and that the presence  
of appendicitis indicated an operation: first,  
because, if operated upon very early, the mor-  
tality is almost *nil*; second, because, if opera-  
tion is deferred, it becomes more difficult after

several attacks, and for this reason and because  
attacks generally increase in severity, the dan-  
ger to the patient's life is enhanced. In the  
early stages of the inflammation the operation  
may be resorted to, or, if the symptoms are  
not pressing, it is preferable to wait until the  
acute symptoms have subsided and then to  
operate before another attack is superimposed  
upon the first.

Dr. Deaver also advised the administration  
of a saline purgative or castor oil in full dose  
to all cases of appendicitis, with the double  
object of removing from the bowel indigestible  
food which may be producing the pain, or, if  
operation is required, emptying the bowel of  
fecal matter.

In the discussion which followed, Dr. McBur-  
ney emphasized very strongly the fact, in his  
opinion, that medical treatment of these cases  
is always and invariably futile, and that in  
many instances an attempt at such treatment  
places the surgeon eventually at a distinct dis-  
advantage, because of the ravages which have  
been produced by the disease before he has  
had an opportunity to operate. He disagreed,  
however, with Dr. Deaver as to the advisabil-  
ity of administering purgatives, as he did not  
believe that the pains of indigestion were diffi-  
cult of separation from the pains of appen-  
dicitis, and did not regard the emptying of the  
bowel, except in extraordinary cases, as a  
necessary preliminary measure to operation.  
He asserted most emphatically that the appen-  
dix was the source of septic infection from the  
very beginning of appendicular inflammation;  
that it provided a fertile field for growth of  
those micro-organisms which, while benign in  
the healthy intestine, speedily become malig-  
nant when, by reason of pathological changes,  
their growth is more active. He expressed the  
belief that the septicæmia arising from this  
local point of infection varied in different in-  
dividuals, according to their power of septic  
resistance, just as one man resists the septic in-  
fection of a severe post-mortem wound and an-  
other dies of a pin-prick while making an  
autopsy. For these reasons he strongly urged  
operation upon every appendix which seemed  
to be in trouble, and, because of his belief in  
its being a source of infection, urged its re-  
moval as early as possible before the general  
system had become infected. Later in his re-  
marks he admitted that he preferred in the ma-  
jority of cases to wait twenty-four to forty-eight  
hours until the acute symptoms had passed by  
before operating, as the results were usually  
better under these circumstances, though,  
should symptoms become fulminating during

this period, operation should not be delayed. After reiterating again and again that all medicinal means were wretched makeshifts in cases of appendicitis, and challenging any medical man present to offer a plan of treatment which could be shown to have any distinctly favorable influence upon the disease, he ceased speaking.

He was followed by Dr. William Osler, of Baltimore, who, as a medical clinician, took the ground that too many appendices were removed and that the operation for appendicitis was passing through the excessive stages which operations upon the tubes and ovaries passed through a few years since. He believes that, while many cases do require operation, many are unnecessarily operated on, and recalled the results of a large number of "post-mortems" made by him in which persons died of other diseases than appendicitis, but in whom evidences of appendicitis having previously existed were present, proving that acute appendicitis could occur with entire cure, without operative interference.

Dr. Hare inquired of Dr. Deaver whether there was not danger in administering active purgatives to patients in whom a perforated appendix possibly existed, on the ground that through this perforation fecal matter might be swept out into the abdominal cavity, and he quoted a paper of Dr. McBurney's, in which that gentleman had asserted that in all his operations he had never found fecal matter in the *caput coli*, and that for this reason the administration of a purgative was not needed.

Dr. John Ashhurst then took the ground that Dr. Deaver and Dr. McBurney were far too advanced in their views in regard to operations for appendicitis. He quoted a number of cases in which he had seen active medicinal measures produce cures, and he protested in the name of conservative surgery against the extreme views entertained by the first two speakers, stating that, in his experience, the application of ice over the right iliac fossa and the administration of opium until the respirations dropped to 12 a minute had removed acute inflammations of the appendix in a large proportion of cases. He did not for a moment deny that operation was often needed, but he did assert that it was by no means indicated as a measure of first resort in every case.

Dr. A. V. Meigs, in his remarks, practically agreed with those made by Dr. Ashhurst, and while expressing his willingness to call in a surgeon as a consultant in all cases of appendicitis, declined to admit that surgical aid was necessary in all instances.

In closing the discussion, Dr. Deaver stated that he had seen instances in which the administration of purgatives in cases of perforated appendices had resulted in the escape of fecal matter into the peritoneal cavity.

As a result of this and other interesting discussions upon this most important topic, we think that fairly definite ideas as to what the general practitioner should do in such cases have been obtained.

In the first place, in many instances he will relieve himself of some responsibility if, from an early stage of the disease, he call to his aid in diagnosis a surgical consultant, who will be called in not to operate, but to watch the case from a surgical stand-point, to determine at its various stages whether an operation is necessary. A surgeon should be chosen who is neither ultra-radical nor ultra-conservative, who will neither urge operation too soon nor postpone it too late; and he should be a man who, while skilled in surgery, has enough regard for the opinion of the medical clinician to permit his own judgment to be influenced by medical opinions, should good reasons be adduced why an operation should not be done, for it is evident that we are rapidly approaching a time when the operation for appendicitis will not be so frequently performed by those who are now reaping a harvest of appendices.

It is also evident that cases of appendicitis may be divided into three classes: those which are fulminating or gangrenous from the moment of their invasion, and which in the majority of the cases are fatal—whether operated upon or not; second, those in which medicinal measures or measures applicable by a medical man, such as the application of cold and leeches and opium, are to be tried, and, these failing, operation resorted to soon or late, according to the rapidity of development of the attack; and, third, those cases of appendicitis which, with perfect safety and with entire cure, may remain untouched by the knife, and in which purely medical measures bring about the results desired.

While an attack of appendicitis may predispose a patient to subsequent attacks, operations to avoid attacks cannot be considered as advisable, since they simply deal with the possibilities and not certainties of the future, and it is only after a man has had one severe or several rapidly succeeding attacks of appendicitis that an operation should be resorted to during the period of quiescence as a prophylactic measure.

An interesting part of the discussion was the statement by Dr. S. Weir Mitchell that in some

cases of appendicitis post-operative neuroses or other nervous complications sometimes occur, and that he knew of a case, or cases, in which, following operation, the pain and discomfort in the abdomen were so excessive as to incapacitate the patient from all employment and to render the remedy worse than the disease.

Dr. Deaver also called attention to the fact that the removal of a chronically diseased appendix relieved chronic intestinal dyspepsia and diarrhoea in many cases, a fact first insisted upon by Dr. J. H. Musser, of Philadelphia.

#### OPERATION FOR CURE OF CARCINOMA OF THE BREAST.

**T**HIS subject, always a live one from the frequency with which the disease is encountered and from its almost uniform fatality, whether operation be performed or not, has again been revived by Halsted ("Johns Hopkins Hospital Reports," vol. iv., No. 6), who claims as the result of more thorough operation, than is generally performed, results so very much better than those usually obtained that his paper merits most careful attention.

Of forty-five cases in which full details of the post-operative course were obtainable, there was local recurrence in three, regional recurrence in eight more. By local recurrence is meant a return of the disease in an apparent or buried scar. Billroth, by regional recurrence, designated a return of the cancer in or about a scar after a long time, explaining these cases on the basis of the cancer diathesis.

Halsted reserves this term for skin metastases at a greater or less distance from the scar, holding that the surgeon has no guide for the so-called lenticular and apparently discrete metastases of the skin, since one may literally flay the patient's chest and side only to find some weeks or months later one or more cancer nodules in the skin of the neck, back, or abdomen. He states that these lenticular skin metastases are distinguished from local recurrences in that they are believed to have formed against the lymphatic current and to have no connection either with the original tumor or with each other. So far as local and regional recurrence is concerned, seventy-three per cent. (thirty-four) are entirely free; there has been a true local recurrence in six per cent. In all of the fifty cases the axillary glands were more or less involved. In seventeen cases the highest intracavicular glands were also infiltrated. In only seven cases was it recorded that this gland

was healthy. In at least five cases the supra-clavicular glands were also diseased.

Halsted acknowledges the service rendered to surgery by Volkmann when he showed that, even though cancer was apparently not attached to the pectoral muscle, nevertheless the malignant growth quickly penetrates to the fascia. Heidenheim claims, indeed, that when carcinomata have involved the lymphatic channels, they invariably send rootlets to the surface of the muscle, no matter what the thickness of the layer of fat between the breast and muscle may have been; the muscle itself remains healthy for a long time. Necessity for cleaning out the axilla, even when palpation through the healthy skin shows no glandular enlargement, is now pretty generally recognized, and in contrasting the results in his cases with those of others, Halsted tabulated the work of those who recognize this general principle.

Volkmann excised the pectoralis major and sometimes the minor muscles in thirty-eight of his worst cases. In thirteen of these there was neither local nor regional recurrence. In the milder cases the muscles were not removed, and in these the percentage of local recurrence was larger than in the more serious cases.

On the basis of three years' immunity after operation for radical cure, Halsted quotes the operative results in the practice of some distinguished surgeons as follows: Bergmann (Eichel), 30.2 per cent.; Billroth (V. Winnivarter), 4.7 per cent.; Fisher (Henry), 9 per cent.; Gussenbauer (Fink), 16.7 per cent.; König (Hildebrand), 22.5 per cent.; Küster (Schmidt), 21.5 per cent.; Lucke (Dietrich), 16.2 per cent.; Volkmann (Sprengel), 14 per cent.

Halsted's operative technique is as follows: An incision is made around the breast, going wide of any infiltrated skin. This incision is continued upward and outward just below the level of the clavicle to a point on the anterior surface of the shoulder corresponding to the head of the humerus. The cut is carried at once and everywhere through the fat, the skin is dissected outward and to the lower edge of the pectoralis major muscle at the position where the fat forming the superficial fascia of the chest is continuous with that of the axilla.

The costal insertions of the pectoralis major muscle are severed, and the splitting of the muscle, usually between its clavicular and costal portions, is begun, and continued to a point opposite the scalenus tubercle on the clavicle. At this point the clavicular portion of the pectoralis major muscle and the skin overlying it

are cut through hard up to the clavicle; this cut exposes the apex of the axilla. The loose tissue under the clavicular portion (the portion usually left behind) of the pectoralis major is carefully dissected from this muscle as the latter is drawn upward by a broad, sharp retractor; this tissue is rich in lymphatics and is sometimes infiltrated with cancer,—an important fact.

The splitting of the muscle is continued out to the humerus, and the part of the muscle to be removed is now cut through close to its humeral attachment. The whole mass—skin, breast, areolar tissue, and fat circumscribed by the original skin incision—is raised up with some force, to put the submuscular fascia on the stretch, so that it is stripped from the thorax close to the ribs and pectoralis minor muscle. It is well to include the delicate sheath of the minor muscle when this is practicable. The lower outer border of the minor muscle having been passed and clearly exposed, this muscle is divided at right angles to its fibres and at a point a little below its middle. The tissue—more or less rich in lymphatics and often cancerous—over the minor muscle near its coracoid insertion is divided as far out as possible and then reflected inward, in order to liberate or prepare for the reflection upward of this part of the minor muscle.

The upper, outer portion of the minor muscle is drawn upward with a broad, sharp retractor. This liberates the retractor, which, until now, has been holding back the clavicular portion of the pectoralis major muscle.

The small blood-vessels under the minor muscle, near its insertion, must be separated from the muscle with the greatest care. These are embedded in loose connective tissue which seems to be rich in lymphatics and contains more or less fat; this fat is often infiltrated with cancer. These blood-vessels should be dissected out very clean and immediately ligated close to the axillary vein. The ligation of these very delicate vessels should not be postponed, for the clamps occluding them might of their own weight drop off or accidentally be pulled off, or the vessels themselves might be torn away by the clamps. Furthermore, the clamps,—so many of them,—if left on the veins, would be in the way of the operator.

Having exposed the subclavian vein at the highest possible subclavicular point, the contents of the axilla are dissected away with scrupulous care, also with the sharpest possible knife. The glands and fat should not be pulled out with the fingers. The axillary vein should be stripped absolutely clean. Not a particle of

extraneous tissue should be included in the ligatures which are applied to the branches—sometimes very minute—of the axillary vessels. In liberating the vein from the tissues to be removed, it is best to push the vein away from the tissues rather than, holding the vein, to push the tissues away from it. It may not always be necessary to expose the artery, but it is well to do so. Sometimes the tissue above the large vessels is infiltrated. It is best to remove all the loose tissue above the vessels and about the axillary plexus of nerves.

Having cleaned the vessels, we may proceed more rapidly to strip the axillary contents from the inner wall of the axilla,—the lateral wall of the thorax. We must grasp the mass to be removed firmly with the left hand and pull it outward and slightly upward with sufficient force to put on the stretch the delicate fascia which still binds it to the chest. This fascia is cut away close to the ribs and serratus magnus muscle.

When we have reached the junction of the posterior and lateral walls of the axilla, or a little sooner, an assistant takes hold of the triangular flap of skin and draws it outward, to assist in spreading out the tissues which lie on the subscapularis, teres major, and latissimus dorsi muscles. The operator, having taken a different hold of the tumor, cleans from within outward the posterior wall of the axilla. Proceeding in this way, we make easy and bloodless a part of the operation which used to be troublesome and bloody. Each bleeding-point is stopped as quickly as possible with an artery forceps. The edges of the wound are approximated by a buried purse-string suture of silk. The triangular flap of skin is used as a lining for the fornix of the axilla; hence the apex of this flap is shifted to a new and lower position. The axilla is never drained and invariably heals by first intention. The uncovered wound often heals by the so-called organization of the blood-clot.

As to the possible disability produced by the operation, it is in most cases so slight as to be absolutely inappreciable. In the majority the arm of the side operated upon has been quite as useful as before the operation.

A study of Halsted's tables shows that of the forty-five cases in which the results as to local recurrence are known, in ten but six months or less have passed since operation. Of the thirty-five remaining cases, there was local or regional recurrence in eleven; also, it must be noted that the period of three years or over without local recurrence has been passed by but four. In one of these, knowledge as to

local or general recurrence was not obtainable. Considering these points, it is still evident that Halsted's results are very much better than any heretofore published. It is true, as he states, that many surgeons of large experience have never seen a cancer of the breast cured. It is also true that the operation as performed by the majority of surgeons in this country offers absolutely no hope of permanent cure and but little chance of non-recurrence *in loco*.

Aside from the figures he gives, the operation he proposes is from theoretical grounds clearly indicated. The tabulation of his cases proves the practical working of this procedure. It is probable that, even with an operation as thorough as that of Halsted's, the ultimate mortality of cancer will still be large, since, before the patients present themselves, the disease will often extend far beyond the reach of his knife; yet, if we can hope for a cure in even twenty per cent. of the cases, this represents an enormous advance in our surgical attainment.

## Reports on Therapeutic Progress.

---

### GERMAIN SÉE ON FERRATIN.

The distinguished French savant, PROFESSOR GERMAIN SÉE, reported his views on the therapeutic value and place of ferratin to the Academy of Medicine of Paris, August 21, 1894.

Professor Germain Sée said that he had found occasion during his attendance at the Hôtel-Dieu to employ ferratin and to study its effects on various clinical cases, which he took pleasure in reporting. Ferratin seemed to have a direct significance in the nutrition of the tissues, and even after prolonged use it produced no derangement of the stomach or intestines. It had a pronounced curative effect. Its action was mildly astringent, without causing hurtful excitement or constipation, disturbances commonly following the use of ordinary ferruginous preparations; but, as a remarkable fact, it caused a strong increase of appetite—always precarious and capricious in anæmic patients—and also regulated the movements to a normal condition. Its administration was free from any unpleasant side- or after-effects.

Ferratin, .5 to 1.5 grammes per day in divided doses, was primarily a valuable food-product; it excited appetite and thereby offered a powerful adjuvant in permitting the absorption of food, and it contained a fixed

proportion of iron which was highly assimilable, and thus replaced a vital insufficiency.

The administration of ferratin, said Professor Germain Sée, was indicated in those suffering from anæmia from hard work, though the patients have the appearance of good health; those of both sexes affected with chlorosis; those weakened by too rapid growth and puberty; those fatigued by study; and, in short, all in whom a diminution of red blood-corpuscles had ensued, due no matter to what causes.

Professor Germain Sée concluded his report by promising that he would keep the Academy informed as to his further studies of ferratin, which he was conducting simultaneously at the Hôtel-Dieu, in his medical clinic, and in his physiological laboratory.—*American Therapist*.

---

### POTASSIUM NITRATE IN THE TREATMENT OF PHLEGMASIA ALBA DOLENS.

HOVNANIAN describes his use of nitrate of potassium in this affection in the *Medical News* of July 28, 1894.

It has fallen to his lot to treat three well-marked cases of phlegmasia alba dolens with potassium nitrate with such gratifying results as to seem to justify publication.

Mrs. H., twenty-three years old, was delivered of her first child by her family physician with instruments, and sustained extensive lacerations of the cervix uteri and perineum, which at the time were not repaired, but were left for a secondary operation. Twelve days after delivery she complained of pain and heaviness in the left leg, and within three days there developed well-marked phlegmasia. On the fourth day of this complication the writer saw the patient in great agony, with a temperature of 105.2° F., a pulse of 130, and respirations 25. The limb was so turgid and swollen that there seemed to be great danger of gangrene or rupture. The woman was at once given morphine sulphate ( $\frac{1}{3}$  grain) hypodermically, and her limb was wrapped with cotton and placed on a feather pillow at a very obtuse angle. Hovnanian then prescribed a solution of potassium nitrate in water, representing 5-grain doses, to be given every hour until his return. Seven hours later he found his patient in better condition, with a temperature of 103° F., a pulse of 112, and respirations 22, and with less pain and discomfort. The swelling seemed to be less tense and the veins less engorged. The nitrate was continued as before until morning, when he found her in yet better condition. She had slept well during the night, although

she had been wakened regularly for her medicine. Her temperature was 100° F., her pulse 95, her respirations 20. The swelling was reduced to less than half, and the returning circulation was fairly well established. There was no pain whatever and but slight tenderness on pressure. The medicine was continued every two hours during the day, until the author saw her late in the evening, with a temperature of 99° F., a pulse of 90, and respirations 18. The swelling had almost entirely gone and everything was in good condition. The nitrate was continued for two days in smaller doses and at longer intervals, and then discontinued.

Two other equally typical cases are also recorded in this paper.

#### TREATMENT OF HERNIA IN CHILDREN.

The *Post-Graduate* for September, 1894, contains an article by DE GARMO, in the course of which he asserts that the knife is seldom needed in the cure of hernia in early life. There may be reasons in some cases when it is better to obtain a cure in two or three weeks by operation, rather than have the child wear a truss for one or two years. If, however, the matter is honestly placed before the parents, it will be found that in almost every instance they would prefer bringing the child regularly to the physician for a year or more until cured, to having the operation.

These are tempting cases to the over-ambitious young surgeon, as almost any operation is followed by cure.

Mechanical treatment can be begun at any time after the child is ten days or two weeks old; the earlier the better. It is an erroneous and unfortunately common idea that children will "outgrow" this defect.

There is no bandage or makeshift of any description that will take the place, either for comfort or efficiency, of a carefully applied truss containing a metallic spring.

What style of truss, of the many on the market, shall we select, for there are many good ones and many bad ones. All infant trusses should be condemned which are made to apply from the same side of the rupture; this includes all German or French styles, also all of those whose pad is placed upon a descending arm at a level lower than the pelvic spring, and all trusses cushioned or padded with soft material.

The springs should be so tempered that they may be bent to the exact shape of the child's body, and the entire truss should be imper-

vicious to moisture, that it may be frequently washed.

The more simple it is in construction the better. For the treatment of a single inguinal hernia in childhood, the spring, which from the pad crosses the front of the abdomen, passes around the hip of the opposite side and across the back, is one of the most valuable appliances that can be used; it can be found in almost every drug-store in the land. Covered either with hard rubber or celluloid, it is known in the trade as a "cross-body" truss. The celluloid have the advantage of being readily shaped without heating the spring, but are not as durable as those covered with rubber; both are excellent trusses.

The author uses in his private practice and clinic a German-silver spring made on the "Hood" pattern, which has given him great satisfaction. A similar truss has been made with celluloid covering and is known to the trade as the celluloid Hood truss.

The measure for selecting the size of the truss should begin just above where the hernia is seen,—i.e., over the internal ring,—and pass around the hips midway between the crest of the ilium and the trochanter major, to point of starting, giving the circumference in number of inches.

The method of taking the shape by means of a strip of sheet-lead, as taught by the writer for many years, is a great aid. It consists of securing a tracing on paper of the exact shape of the hips at the point covered by the truss-spring. A piece of sheet-lead one-sixteenth of an inch thick, about half an inch wide, and long enough to go at least two-thirds around the child, is used for this purpose. Place one end of the lead over the inguinal canal, with the strip resting across the abdomen. Mould the lead to the shape of the abdomen and pass it around the hip opposite to the hernia and across the back. Press the lead to the exact shape of the hip and back, and then slip it off, place on a sheet of paper, and make a tracing of its inner surface with a pencil. The shape of the other hip may be taken in the same way, giving an approximately correct diagram of the pelvis. In shaping the spring, this diagram is used instead of the child. If a spring covered with hard rubber is used, it should be passed through the flame of a spirit-lamp until it is quite warm, and it can then be bent to the exact shape required.

In locating the truss-pad, see that its lower edge does not come below the external ring; its pressure should be well over the internal ring.

## LOCAL ANÆSTHESIA.

This subject is one especially interesting to the practitioner who does any minor surgery, and who does not? It is written of by CARR in the *Virginia Medical Monthly* for August, 1894. He says that in the gum or mouth  $\frac{1}{4}$  grain of cocaine is a perfectly safe dose given hypodermically, and it may be repeated safely in ten minutes if no disagreeable symptoms appear. In the neck, face, and scalp  $\frac{1}{2}$  grain may be given as a safe dose, and in the trunk and extremities 1 grain. In these doses no unpleasant effects will be observed unless the patient is very susceptible, and even in the extremely susceptible there will be no danger. If there is any suspicion of the existence of marked idiosyncrasy, and the operation can be put off for a few days, it is a good plan to try the effect of the drug in gradually increasing doses by the mouth. A tolerance for it can in this way be rapidly established.

Whenever the anatomy of the part will permit, a rubber band or ligature should be applied above the seat of operation. This will prevent absorption, and the dose may be largely increased without danger. In operations upon the extremities this can always be done, and 2 grains can be given with safety and to the average individual without unpleasant effect.

The author has given in this way  $4\frac{1}{2}$  grains for the synchronous amputation of three toes, with no effect except some mental exhilaration and talkativeness. He gives no rule as to the safe dose in small children. He has never had occasion to use it hypodermically in any patient under eight years of age.

The following rules should be observed:

1. Keep the syringe in good working order, clean and aseptic. Use a small, sharp needle and boiled water.

2. Use a four- to eight-per-cent. solution.

3. Disinfect the part with a sublimate solution (1 to 1000 or 1 to 500) before using.

4. In making the first injection, choose the least sensitive spot central to the site of operation, or even two inches distant. Inject at first only a third or a fourth of the quantity you expect to give.

5. If possible, put a rubber ligature around the part above your injection. Make this ligature just tight enough to stop the circulation and prevent bleeding while you are operating; it need not be tight enough to cause much discomfort. This prevents constitutional symptoms and prolongs the local effects.

6. Wait until you get the effect of the first injection, which may be five minutes, or even ten or twelve minutes if it was placed deeply.

Then make all subsequent injections by passing the needle through the skin where it has lost sensation and running it along under the skin in the direction indicated.

7. Before beginning to operate, pass the needle all around and beneath the field of operation to see if all parts have been thoroughly anæsthetized. If not, inject a little more at the sensitive spots.

8. If sutures are needed, place them before removing the rubber band, but do not tie them until the band is removed and the bleeding checked. Sensibility soon returns after removing the ligature.

9. If a large dose has been used and constitutional effects are feared, put the ligature back after the operation and leave it for an hour or so. He has found that whiskey intensifies the effects, but that strychnine relieves them promptly, and he considers a hypodermic of strychnine the best antidote to cocaine-poisoning. Cocaine must be used hypodermically on all parts covered by sound skin, but on mucous membranes this is, as a rule, unnecessary and unadvisable. In the mouth and nose, it is best applied by a spray or by rubbing a cocaine tablet over the part to be affected. The latter method is more effective if the tablet can be held against the part for several minutes without producing cough or gagging. Anæsthesia thus produced is incomplete, superficial, and of short duration, but sensation in the mouth is not acute, and it answers a good purpose. Its hypodermic use in the mouth gives no better results. 2 or 3 grains placed in tablet form in the uterus and cervical canal will render dilating and curetting painless, provided we give it fifteen or twenty minutes for absorption, and do not pull the uterus down to do the operation. In operating for lacerated cervix, it is better to inject it into the cervix. Pulling down the uterus for either of these operations is usually unnecessary and Carr thinks is to be condemned. For chancroids and ulcers, it is only necessary to lay a tablet on the surface and allow it to dissolve in the secretion, or, if the surface is large, powder one or two tablets and sprinkle over it; this is much more efficacious than a solution. The same rule holds in the urethra. For passing the sound in a very sensitive urethra, it is only necessary to inject enough of a two-per-cent. solution to distend the urethra; but for cutting strictures, a few drops of a saturated solution, or, better still, a tablet, should be carried back to the stricture. For enlarging the meatus, it is only necessary to place a tablet just within the opening and let it dissolve.

There are many uses for local anæsthesia that are not surgical. The pain of incurable cancers may often be greatly palliated by local applications of cocaine, and carbolic acid in the form of an ointment or of suppositories; and a similar ointment will be found efficacious in superficial neuralgias and other painful affections of the skin. In all chronic affections, however, we should use it cautiously, for fear of inducing the cocaine habit.

In this connection may be mentioned a fact well worth knowing, that chordee may be entirely and promptly relieved by putting on a condom containing 2 or 3 drachms of a two-per-cent. solution of carbolic acid, and that any pain in the penile portion of the urethra or pendulous penis may be controlled in this way. The writer had a patient with a mixed chancre in the meatus who suffered great pain upon mic-turition. He recommended the condom, and he experienced the greatest relief from putting it on for fifteen or twenty minutes before urinating.

#### *BENZONAPHTHOL AND BISMUTH SALICYLATE IN SUMMER DIARRHŒA.*

The term summer diarrhœa is here used to include the various forms of gastro-intestinal disturbance occurring during warm weather, and especially characterized by frequent, loose, or even fluid discharges from the bowel, sometimes attended with pain, sometimes attended with fever, sometimes associated with nausea and vomiting.

While the pathology and etiology of these various forms of disturbance of the alimentary canal vary in particulars, the general factors are the same: an indiscretion in diet, special or general, remembered or forgotten; over-heating or over-exertion in the heat; irritation or inflammation of the gastro-intestinal mucous membrane in whole or in part; bacterial activity; intoxication by absorption of noxæ from the intestines. After the alimentary canal has been cleansed of irritating materials by the most available means, which may be, according to circumstances, lavage of the stomach, irrigation of the bowel, or the administration of a purge, usually calomel, or a mixture of castor oil and spiced syrup of rhubarb (equal parts), and after the diet has been duly regulated, Cohen has observed very satisfactory results from the administration of the following combination:

**R** Benzonaphthol,  
Bismuth salicylate,  
Dover's powder, of each, gr. v.  
In capsule. cachet. or powder.

To an adult, 1 capsule is given every three hours, or as necessary. It is rarely needful to exceed four doses in the twenty-four hours. To children, the same preparation may be given in reduced dosage; thus, to a child of two years he has given,—

**R** Benzonaphthol, gr. ii;  
Bismuth salicylate, gr. ii;  
Dover's powder, gr. ss.

In the mildest cases benzonaphthol alone has proved efficient, and in many cases the opium is unnecessary; but, as a rule, the combination of the three ingredients in the proportions stated is more promptly efficacious, if present experience can be relied upon, than any other routine treatment he has used. The past season is the second one during which he has employed it.

A word may be added as to diet. It is best, under the conditions stated, to make a complete change in the food, whether of child or of adult. If a child is taking milk in any form,—sterilized, boiled, predigested, or plain,—all milk should for the time being be cut off. It will not harm a child to go without food for a day or two, but as parents cannot readily be brought to see this, it is best to give some substitute. Barley-water and (home-made) beef-juce are the most available. They may be given alternately in small amounts,—from 2 to 4 ounces of barley-water; from 1 to 4 drachms of beef-juce, freshly prepared, every third or fourth hour. If a child has been sick for some time and is much run down, alcohol (from 10 to 20 drops of brandy or whiskey) may be added, or given with water between food-times. Smaller quantities of beef-juce, given more frequently, may sometimes be called for by the special conditions of a particular case. If a child is taking various kinds of food, but not much milk, boiled milk with pancreatic powder may be given, as with adults. As a rule, however, it is advisable to avoid milk until the alimentary canal is rendered aseptic, for milk is quite liable to undergo deleterious change after being swallowed as well as before,—a point that is frequently overlooked.

In the case of adults, it is usually safe to give boiled milk, in some instances adding sufficient pancreatin and sodium bicarbonate to accomplish artificial digestion in the stomach. He usually prescribes 2½ grains of pancreatin and 7½ grains of sodium bicarbonate (*i.e.*, 1 drachm and 3 drachms respectively, divided into twenty-four powders, in waxed papers), to be dissolved in an ounce of cold water, and the solution added to

a teacupful of warm (previously boiled) milk; this is taken every third hour. When the patient refuses milk, or it is for other reasons objectionable, beef-juice, barley-water, tea, coffee, sherry and water, whiskey and water, claret and water, and the like may be given in small quantities. In most cases the whole question of 'alimentation' is a negative rather than a positive one,—to avoid food that will ferment or decompose, or otherwise give rise to irritating products or toxins, for recovery is usually so prompt that the problem of maintaining nutrition does not arise. It is usually best to give water freely, aerated water being preferable.—COHEN, *Medical News*, July 28, 1894.

### CONJUNCTIVITIS, ACUTE AND CHRONIC.

MOORE contributes an article on this subject to the *Post-Graduate* of September, 1894. This is, perhaps, one of the most obstinate forms of acute or subacute conjunctivitis to deal with, unless the cause is appreciated. It is best in all cases of conjunctivitis to examine the tear-passages and ascertain their condition. If there is obstruction, treat the nasal end of the lachrymal duct by sprays or powders, and use mercuric bichloride (1 to 8000) on the conjunctival cul-de-sac. If this does not remedy the lachrymal obstruction, then open the canaliculus by the Bowman operation, thus giving free drainage. This, with the use of the antigermicide, will cure the condition. These cases, treated in the ordinary way by the application of astringents to the eyelids, will, as a rule, avail nothing, but speedily respond to the treatment outlined above.

Nasal conjunctivitis, by which we mean inflammation of the mucous membrane of the eyelids, due not to obstruction of the lachrymal duct, but to an interference in the free nasal breathing and ventilation of the head through the nose, due in most instances to a hypertrophic rhinitis, and, perhaps, to enlarged tur-nated bodies. The symptoms of these cases persist even when the most approved method of treatment have been used for simple conjunctivitis, and the redness of the eyelids and the blepharitis only gives way when the nasal obstruction and rhinitis is under control. We could cite many cases where this cause had been overlooked, and which speedily recovered on the treatment of the nose and throat.

Traumatic conjunctivitis is frequently met with as the result of the injury of the mucous membrane by the entrance of foreign substances, and which speedily gives way on the

removal of the exciting cause. After exposure to the sun's rays, or the impact of air in sailing or rapid driving, we frequently observe a form of conjunctivitis, which we justly call traumatic. We have all seen, doubtless, the conjunctiva sun-burnt and air-inflamed. For these forms we use the application of cold compresses ten minutes at a time, four times a day, together with protecting colored glasses and moderate out-door exercise; in fact, most all the simple forms of conjunctivitis do much better in the air than when housed. Occasionally, in traumatic conjunctivitis, with moderate secretion, an eye lotion of alum and boracic acid, three grains each to the ounce of water, will be found efficient and soothing. Electric-light conjunctivitis comes under this class, and is now quite often seen, especially in those engaged in works where the arc light is used. Protection of the eyes by colored glasses and abstinence from the usual employment for a few days will usually rectify this difficulty.

In the treatment of all the forms of simple, acute, or subacute conjunctivitis, we are in the habit of prescribing applications to be made to the closed eyelids of cold water, by means of cloths or pieces of old linen. These dipped in cold water or, better still, placed on a piece of ice and then transferred to the eyelids, make a very soothing and beneficial form of treatment. Then a solution of alum and boracic acid, as mentioned above, is given the patient to use at home, 2 drops in each eye, twice daily.

Purulent conjunctivitis is the most serious of all the inflammations of the membrane we have to deal with, and we know of nothing more sad than the picture so frequently seen of the helpless infant, but a few days old, presented for our care, with both corneæ infiltrated, the eyelids bathed with pus, and the eyes hopelessly destroyed, when, if the appropriate remedies had been used, the child would have been saved a lifetime of misery. Another form seen in the adult is the purulent conjunctivitis caused by the germ of gonorrhœa,—an exceedingly disastrous inflammation, and one that will destroy the eye within forty-eight hours unless treatment is very promptly inaugurated. The eyelids are very much swollen, and the skin red and glossy, and the secretion copious. In either the infant or the adult, if only one eye is affected, the non-affected should be protected and shielded from inoculation by means of "Buller's shield," which is simply a watch crystal held in position by means of adhesive plaster. Thorough cleanliness is godliness in this instance, and should be rigorously carried

out; in fact, this class of patients should only be treated as in-door patients, and then isolated. All things used in removing the secretion from the eyelids should be promptly incinerated, and thus all further danger of contagion removed. The eyes should be cleaned as often as the secretion accumulates,—every half-hour, if necessary. The eyelids should also be opened and the secretion removed by the use of a small syringe, injecting through the cul-de-sac and over the eyeball a solution of mercuric bichloride (1 to 8000), in order to cleanse and, at the same time, act as an antiseptic. If the secretion is considerable and there is not much bleeding from the palpebral conjunctiva, applications should be made by the medical attendant to the everted eyelids of a solution of silver nitrate, ten grains to the ounce of water. This should be in many cases applied twice daily, and continued until the secretion begins to diminish, when the strength of the solution may be reduced to five grains and the applications made once daily. It is extremely important that applications of iced cloths should be kept up in the adult continuously for the first few days and in the infant as frequently as tolerated. The best way is to take a large piece of ice, wrapped in flannel, and upon this place small squares of old linen, and when they are thoroughly cold transfer them to the closed and inflamed eyelids. When the cold becomes too intense, the applications may be interrupted for a time, or when the cornea shows signs of lack of nutrition, they may be altogether omitted, and even warm compresses applied; this, however, is rare. After cleaning and making the silver-nitrate applications, it is best to fill the conjunctival cul-de-sac with vaseline, as it has been found to lessen the secretion and probably render the propagation of the germs more difficult.

#### CHOICE OF ANÆSTHETIC FOR REMOVAL OF NASO-PHARYNGEAL ADENOIDS.

In the *Medical Chronicle* for August, 1894, MORITZ goes carefully over this subject, which has lately been discussed at a joint meeting of the London Laryngological Society and the Anæsthetists' Society, and, considering the frequent occurrence of cases of naso-pharyngeal adenoids, it must be acknowledged that the subject is one of considerable interest.

Wyatt Wingrave, in a letter to the *British Medical Journal*, drew renewed attention to this subject. He says that he has administered anæsthetics for tonsillotomy and removal of

adenoids upward of eleven hundred times. In about ninety per cent. of these cases he has given nitrous oxide gas alone, administered through a modified Clover's gas and ether inhaler, the patient being in a sitting posture, a mouth-prop being inserted before applying the face-piece, while the whole operation was usually completed in less than forty seconds. The supplementary administration of a few whiffs of ether was not always satisfactory, as it increased the struggling and bleeding. In less than twelve cases a second administration of gas was required. He warns against the use of chloroform in these operations, and collates five cases of death under chloroform for removal of adenoids, recorded in the *British Medical Journal* and *Lancet* since May, 1892. He remarks that the use of gas was prompted more "by humanitarian" reasons than with the object of combating serious pain.

Holloway draws attention to two more deaths which had occurred within a fortnight from the administration of chloroform for the removal of adenoids, and he urges again the advisability of being satisfied with the anæsthesia obtainable by nitrous oxide, as generally done at the Central London Throat Hospital. Mr. G. C. Wilkin also uses nitrous oxide, while Dr. Storry administers ether. Mr. Grant Morris, anæsthetist at St. Thomas's, prefers chloroform. He keeps the patient on his back, with the head hanging over the end of the table, and he does not push the anæsthetic, so that the cough reflex will not be abolished.

At the meeting of the Laryngological Society, held on April 11, 1894, of the sixteen gentlemen whose speeches are reported, six are in favor of nitrous oxide alone; but two of these let the inhalation of  $N_2O$  be followed by an inhalation of oxygen, and three of them by the administration of ether in more severe cases. Two gentlemen always administer  $N_2O$  and ether; one,  $N_2O$ , ether, and chloroform; and four give chloroform at once, two giving it until deep anæsthesia, while two others do not push the anæsthetic quite so far.

Considering the diversity of these predilections, Dr. Semon, the president, was therefore justified in pointing out that the discussion had proved the impossibility of laying down arbitrary laws on this question. He considers the practice of performing such operations on out-patients very deplorable, and he objects strongly to the induction of complete anæsthesia; the ocular reflex should be abolished, but the cough reflex should not.

Latterly, the writer has followed the plan advocated by Wroblowski, of Warsaw, who

either paints the parts to be operated upon with a solution of antipyrin (2 parts), cocaine (1 part), and water to 10 parts; or, better still, paints with a ten-per-cent. cocaine solution, and injects a few minutes after in two or three places, under the mucous membrane in each place, 2 minims of a fifty-per-cent. antipyrin solution. Wroblowski was able to remove in this way, painlessly, lamellæ of a deviated nasal septum, operations which lasted half an hour; and the author confirms Wroblowski's statement that not only tonsils and adenoid vegetations may in this way be removed without pain, but that there is no pain afterwards. Wroblowski applies these solutions with similar good results in removal of the lingual tonsil,—a very painful procedure,—and after injecting a few drops of the antipyrin solution under the mucosa with a Heryng's laryngeal syringe, he is able to do painlessly prolonged laryngeal operations. The same application he has made in cases of tubercular ulceration of the larynx where deglutition has become painful and for solid substances impossible. In a patient of this sort, who had not been able to take solid food for about six months, one hour after the injection of a fifty-per-cent. antipyrin solution into the region of each arytenoid body (one division of a Heryng's syringe, equal to  $1\frac{1}{2}$  grains of antipyrin, being applied in each place), the patient was able to eat a beefsteak. Soon after the injection a slight burning sensation is felt. This lasts about fifteen minutes; then the local anæsthesia commences, and the loss of sensation lasts from six to twelve hours. The ulcerative tubercular process itself seemed to be favorably influenced by these injections. The author is applying at present, with similar favorable results, a paint (ten per cent. cocaine and thirty per cent. of antipyrin) twice a day to the larynx of a tubercular patient, in whom the deglutition of the saliva even had become extremely painful, and who is now able to take food and to swallow for six to eight hours after each application.

The local application of strong solutions of antipyrin to mucous membranes deserves, therefore, a much wider trial.

Where general anæsthesia is indicated for the removal of adenoids, attention might also again be drawn to bromide of ethyl, so ardently recommended by Hollaender at the Berlin International Medical Congress. This fluid,  $C_2H_5Br$ , has its boiling-point at  $105^{\circ} F.$ ; it therefore evaporates quickly; its odor is similar to chloroform. It was first used as a general anæsthetic by Thomas Nunneley, of Leeds, in 1869, who for some time did all his eye opera-

tions at the Leeds Infirmary with this anæsthetic. Since then it has been extensively used both in America and in France, mostly for dental operations. Unfortunately, several deaths have been recorded, but Hollaender and others ascribe these to the use of an impure preparation, as until recently it was somewhat difficult to obtain the pure drug, "ethyl bromide,"  $C_2H_5Br$ , owing to the frequent admixture of ethylene bromide,  $C_2H_4Br_2$ , a very poisonous drug. Hollaender administers ethyl bromide with an Esmarch chloroform inhaler, holding it closely over the mouth and nose to exclude air, and continually dropping the fluid on until anæsthesia is established, which takes place in thirty to forty seconds, and frequently in ten to twenty seconds. The anæsthesia so obtained is not complete, but is sufficient for small operations. The cornea reflex is not abolished, and it is not advisable to wait for its abolition, but only until the uplifted arm falls powerlessly down. Hollaender then at once proceeds to operate; the anæsthesia lasts two to three minutes, and the patient is in another minute fully awake. The pulse remains unaltered; it sometimes becomes even fuller; the pupils are not influenced; vomiting, a stage of excitement, headache, and other bad effects are said to be rare. From 1 to 3 drachms (3 to 10 grammes) of the drug are usually sufficient for an administration. A slow or continued administration of large doses causes considerable excitation and prevents a narcosis altogether. Though bromide of ethyl is said not to influence the heart, it should not be administered to patients with heart-disease. Schmidt also recommends this drug for anæsthesia in removal of adenoids and tonsils, but he finds that he usually requires a larger quantity of the anæsthetic. He has never seen any serious after-effects; but vomiting, he says, takes place occasionally. He therefore prefers to operate early in the morning, and not to give solid food previous to the operation. Schmidt also mentions that frequently the mouth is tightly closed, through contraction of the masseter muscles, so that a gag becomes requisite.

#### THE MANAGEMENT OF FACE PRESENTATION.

DAVIS, of the Jefferson College, in the *Medical News* of July 14, 1894, tells us that the treatment best adapted to secure spontaneous labor in face presentations consists in retaining the membranes unbroken until the time of spontaneous rupture; in sustaining the patient's

strength and conserving her energies by suitable feeding, stimulation, and anodynes, and in placing the patient in such a posture as to favor the rotation of the chin anteriorly. When the face looks towards the left side of the mother's pelvis, she should lie upon the left side, her thighs flexed, and the uterus brought as nearly as possible with its long axis corresponding to the axis of her body during labor-pains. Should the foetal face look towards the right side of her pelvis, she should lie upon her right side. The relation of cause and effect that has been found to exist between obliquity of the uterus in the mother's abdomen and face presentation renders the maintenance of the uterus in a favorable posture during this complication a matter of considerable moment. It is quite possible in such cases for a face presentation to be spontaneously changed into an occipital one, and for the occiput even to rotate spontaneously to the front, if these precautions are observed. The administration of such substances as tend to maintain efficient uterine contractions is certainly indicated in these cases before the membranes rupture. As soon as dilatation is complete, the obstetrician is to choose between radical interference by version, or an effort by the methods of Badoque and Schatz to correct the face presentation by converting it into an occipital one. His choice in this decision should depend upon the size and shape of the mother's pelvis, the comparative size of the foetal head, and the condition of the pelvic floor. When no disproportion exists between the head and the pelvis, and when the pelvic floor, although elastic and resistant, offers no undue obstacle to the mechanism of labor, it is certainly proper to allow the head, under good labor-pains and with good extension, to come down upon the pelvic floor in face presentation, and thus an opportunity be given for the mechanism of labor to proceed spontaneously. When, however, there is a disproportion between the head and the pelvis, as evidenced by pelvic proportions less than the average, ascertained by pelvimetry or a large foetal head, as ascertained by palpation and a thorough vaginal examination under an anæsthetic, the case becomes quite different.

The results of forcible delivery in face presentations under these conditions are anything but satisfactory and encouraging. The literature of the subject abounds in illustrations of difficult deliveries by forceps, craniotomy, and, in some cases, by version, in which the life of the child has been lost and the mother seriously injured. In the light of our present knowledge,

the duty of the obstetrician lies in completely changing the presentation, if the pelvis be roomy, by podalic version under anæsthesia by chloroform, or in so enlarging the pelvis that the mechanism of labor in face presentation can continue.

Podalic version for face presentation is familiar as an expedient, and is, in well-selected cases, a prompt and efficient method of treatment. Symphyseotomy is a procedure of too recent date to occupy an established place in these cases in the resources of obstetric art. His resources for considering this a rational procedure are as follows: Personal observation in four symphyseotomies done for disproportion between the head and the pelvis has led him to remark the decided increase of the oblique diameters of the pelvis that follows the separation of the pubic joint. In three of the four cases the foetal head presented in an occipito-posterior position, in two cases the right occipito-posterior, in one the left. In one of these cases the head presented by the right parietal bone before the pelvis was opened. Remembering the observation by many obstetricians that face presentations are often developed out of occipito-posterior positions, it seems to the author rational that any surgical procedure which should enlarge the oblique diameters of the pelvis, and which naturally favors the descent of the occiput in the arc of the pelvic curve lying between the sacro-iliac joint and the spine of the pubes, would afford rectification of this abnormal presentation. The three cases of occipito-posterior position following symphyseotomy were readily delivered without injury to mother or child.

Obstetricians are familiar with the facility with which faulty presentations of the head and shoulders may be remedied when two conditions are present: first, complete anæsthesia of the mother; and, second, a pelvis of good size in its oblique diameters. Reasoning from the author's experience in the cases cited, these conditions are present after symphyseotomy; and were the spontaneous progress of labor in this presentation to fail, he should much prefer, if the pelvis were of good size and the head not impacted, to perform podalic version; or, if the head were impacted and disproportion existed between the head and the pelvis sufficient to occasion difficulty in labor, the face presentation persisting, the writer should hope for a favorable result from symphyseotomy, converting the face presentation into a vertex presentation, and delivering the occiput in the manner most easily available after the pubic joint had been opened.

## TREATMENT OF TYPHOID FEVER.

In the *Medical News* for July 14, 1894, FISK, of Denver, describes his treatment as follows; he has certainly obtained very good results:

Absolute rest. If the patient is seen early in the attack, as gauged by the absence of rose spots and other constitutional symptoms, the writer gives 5 grains of calomel at night, and follows it with a Seidlitz powder or some saline in the morning, and this is the only administration of calomel during the progress of the disease. He then puts the patient on an absolute milk diet, giving a tumblerful every three hours. As a rule, the writer is not influenced by the patient's ideas that it is impossible to take milk, but determines that by his own observation. When he finds this to be true, he has the milk peptonized, and sometimes changes to buttermilk. Extractive matters in the way of broths and extracts are not used, as they always seem to be harmful.

The turpentine mixture used is becoming well known in our hospitals and is meeting with great favor. It is constituted as follows:

R. Ol. terebinthinæ, ℥ii;  
Ol. ricini, ℥ii;  
Bismuth subnit., ℥iii;  
Mucil. acaciæ, q. s. ad ℥iv. M.

This must be shaken well, and a teaspoonful given in a little water twenty minutes after the goblet of milk.

The turpentine in this formula seems to be sufficient to keep the tongue moist and to stimulate the bowels; the castor oil keeps up the secretions, and the bismuth acts, as is well known, as a dressing to the inflamed mucous surface; the last also has a constipating effect, which is overcome by the administration of castor oil (from a dessertspoonful to a table-spoonful) every other morning. For the restlessness of the first few days, which is especially marked at night, he uses either 5 grains of Dover's powder, to be repeated once or twice during the night, or 10 drops of McMunn's elixir of opium, to be repeated once or twice, if needed. Water, iced, if preferred, is given freely; lemonade, not too sweet, is allowed, but not to conflict with the taking of the milk. Antipyretics, like antipyrin, antifebrin, acetanilid, phenacetin, and even quinine (for its antipyretic effects), are absolutely forbidden. Stimulation he reserves for necessity, as indicated by marked nervousness, a rapid and feeble pulse, and for the stage of convalescence. In both instances whiskey is preferred, care being taken to secure a good quality. Of heart-tonics, strophanthus is given rather a preference, and at times he resorts to hypo-

dermic injections of strychnine. He has never used the cold baths of Brand; at the utmost, sponging with tepid water seems to be sufficient, though not often employed.

He believes that great care must be taken in feeding a patient in the stage of convalescence. He thinks it is well to keep him on the milk diet indicated, increasing, however, the amount, if needed, for a week after the temperature has come to the normal. He then begins to feed very gradually, preferring animal to starchy diet.

It will be seen that the methods employed are quite different from those advocated by others. The strict adherence to a milk diet is, of course, nothing new, and as far back as 1866 we find Dr. Cotting, of Roxbury, Mass., reporting in the London *Lancet* three hundred and seven cases of typhoid fever treated without drugs of any kind and a mortality of only ten per cent.

Professor Osler, in his recent publication, says, "Milk is the staple article of diet, of which from 3 to 4 pints are given in the twenty-four hours." This is about the amount the writer used.

Dr. Hutchinson says, "Milk as an article of diet is unquestionably to be preferred to all others in typhoid fever."

The administration of turpentine was advocated by the late Professor George B. Wood and indorsed by Dr. Hutchinson, though the dose employed was greatly in excess of that found in the turpentine mixture.

#### THE COLD POULTICE AS AN ANTI-PYRETIC IN HIGH GRADES OF FEVER.

BEDFORD BROWN, in the *Virginia Medical Monthly* for September, 1894, advises the use of the cold poultice. He orders that a sufficient quantity of flaxseed meal to prepare a poultice of suitable dimensions be placed in a common earthen bowl, and over this is poured boiling water, while the meal is constantly stirred with a large spoon until cooked to the consistency of soft mush. This material is then spread on a piece of soft cotton cloth, for an adult, about eighteen inches long and twelve or fourteen wide, or sufficiently long to cover the entire abdomen, from the pubis upward, extending at least half-way up the chest, well over the cardiac region, so as to fully cover the heart and half of the chest. This poultice is now covered with another piece of cotton of corresponding dimensions. After being spread and covered, the entire surface to be applied

to the person is frequently besprinkled with ice-water until its temperature goes down to 68° or 70° F., when it is ready for application. At this point the author suggests that the poultice be not spread too thick, as in that case it would prove oppressive to the patient.

The poultice as thus prepared is applied over the chest, from above the cardiac region to the pubis. In the writer's experience with it, which dates back fifteen years, he has never known it produce shock to the nervous system or discomfort to the patient. On the contrary, patients with high fever, who have learned its advantages, will often request it when they feel sensations of rise of temperature. Its work, different from that of the cold bath, is accomplished slowly, gradually, gently, and effectually. The cold poultice applied in this way is a good substitute for the cold bath, without its many disadvantages, dangers, and difficulties of application.

In cases of fever, with a dangerous degree of hyperpyrexia, say 106° or 106.5° F., with delirium, insomnia, constant restlessness, contracted pupil, scanty, high-colored urine, these symptoms clearly indicate that this intense degree of temperature is exerting a destructive influence on the great nervous centres,—the brain and spinal cord; and if prompt measures are not taken to reduce this hyperpyrexia to a safe degree, the brain and spinal cord will be overwhelmed in hopeless ruin. This can only be accomplished either by the cold bath, internal antipyretics, or the cold poultice. In certain cases in the author's practice the latter measure, applied over the entire spinal column, from the cervical vertebræ to the sacrum, with these symptoms, has exerted a marvellous effect in relieving the nervous system, in subduing inordinate nervous erethism, relieving delirium and restlessness, and in promoting sleep.

In a case of this kind, during a relapse from a four weeks' illness, where the temperature approached 106° F., pulse 130, utter sleeplessness, and constant restlessness, a long poultice, at 70° F., was applied from above the cardiac region to the pubis; another, at the same temperature, ten inches wide, was applied over the nucha to the sacrum, and the head having been shaved, an ice-bag was applied over the head. In two hours there was a reduction of two degrees; in twelve hours a reduction of five degrees, with copious warm perspiration, with the result of refreshing sleep, nervous composure, relief of delirium; and reduction of the pulse to 100. On one or two occasions subsequently, when there was manifested a disposition of these symptoms to return, the same remedies were applied, with identical

results, and under the usual treatment the case terminated in recovery.

In the treatment of acute peritonitis the powers of the cold poultice have not been tested by him as an antipyretic and antiphlogistic. He believes that in this class of cases poultices, at a temperature of 70° F., applied systematically at intervals of one hour, would exert a beneficial influence.

There is a certain degree of art to be observed in the preparation of these poultices. They should not be spread so thick and heavy as to weight down the patient and cause a sense of oppression; not over a quarter of an inch in thickness, and then reduced to a uniform temperature, as tested by the clinical thermometer. In cases of temperature not exceeding 102° F., Brown often orders a cold poultice at first made with hot water, and then permitted to cool either by the atmosphere or application of ordinary hydrant- or pump-water, and obtains excellent results.

#### *SOME POINTS IN THE TREATMENT OF TYPHOID FEVER.*

In the *Medical Press and Circular* for August 22, 1894, BROADBENT writes on this topic. In intestinal hemorrhage the treatment on which the author has come to rely is the placing of a large ice bag over the right iliac fossa, the administration of a full dose of some liquid preparation of opium, and the subcutaneous injection of ergotin. 10 or 15 minims of turpentine may also be given every three or four hours. The object of the opium is to paralyze the bowel. The blood poured out into the intestinal canal excites peristalsis, and the peristalsis, in turn, tends to prevent the formation of clot on the bleeding surface, which might seal up the vessels. It must, therefore, be arrested; and it is because opium given by the mouth appears to effect this better than morphine hypodermically that this method of administration is preferred.  $\frac{1}{2}$  drachm of laudanum, or its equivalent of liquor opii, may be given at once. Opium, again, seems to have a certain sustaining power. Astringents, supposed to act directly on the bleeding vessels, are useless; long before they have traversed the twelve or sixteen feet of bowel to reach the ulcers they will have expended their power of coagulating blood or astringing tissues. When the medical man lives at a distance from the patient, the nurses should be provided with an ice bag, laudanum, and hypodermic pellets of ergotin, and have instructions to employ them immediately on the occurrence of serious hemorrhage.

Great caution must be exercised in administering stimulants. The half-fainting condition affords the best opportunity for the bleeding to cease, and the longer the patient can be kept in this state with safety the greater is the chance of the arrest being final. Perforation of the bowel is almost always fatal, but the writer has seen at least two cases of recovery in which, from the symptoms at the time and the formation of a dense mass of thickening between the umbilicus and the right iliac fossa, he has had no doubt of its occurrence. The one chance for the patient is the administration of a large dose of opium or morphine for the double purpose of minimizing the terrible shock which attends perforation and of arresting intestinal peristalsis, and so minimizing the extravasation of the contents and affording an opportunity for adhesions. The writer should not hesitate to inject  $\frac{1}{2}$  grain of morphine under the skin and give 30 or 40 minims of laudanum by the mouth.

We come now to the third great source of danger in typhoid fever,—the protracted high temperature. One of Sir William Gull's pregnant sayings was that the removal of symptoms is not the same thing as the relief of disease. The antipyretics not only knock down the temperature, but the patient also, sometimes fatally. The writer's conclusions are based entirely upon observation, but it is interesting to learn that Roque and Weill have found out that antipyrin arrests the elimination of toxins by the urine without preventing their formation. Quinine has done good in large doses as against high temperature. The most efficacious means of controlling the heat of fever, however, is the application of water to the surface of the body. The good results of the bath treatment have long been known to the profession in this country, but it has not come at all into general use. The principal reason, no doubt, is that cold bathing is usually very distressing to the patient, that the labor involved is great, and that in the general hospitals it is difficult to make the special provision required and to supply the additional number of nurses.

---

*ON THE EFFECT OF GIVING LEVULOSE  
AND INULIN TO PATIENTS SUFFERING FROM DIABETES  
MELLITUS.*

HAYCRAFT records the results obtained in three cases of diabetes by giving levulose as a carbohydrate food. The patients were placed on a fixed diet, from which the carbohydrates

were excluded as far as possible and the sugar estimated in the urine. In alternate periods of three days, fifty-five grammes of levulose were given per diem in six doses. The quantity of sugar excreted was determined by Fehling's solution and by polarization.

In the first case (one of acute diabetes) the average increase of sugar excretion in the urine produced by the administration of levulose was one hundred and six grammes for the period of three days. During this period the patient had taken fifty-five multiplied by three equals one hundred and sixty-five grammes of levulose. Of this, nine grammes (equals five per cent.) were excreted again as levulose; ninety-seven grammes (equals fifty-nine per cent.) were excreted as glucose; fifty-nine grammes (equals thirty-seven per cent.) remained in the organism. Similar results were obtained in a second case of acute diabetes.

In a third case (one of chronic diabetes in an old person) all the levulose taken was utilized in the organism, and there was no increase in the glucose excreted.

Experiments on rabbits showed that glycogen can be formed from levulose. A rabbit was kept without food for six days. (At the end of this time one may assume that all the glycogen in the liver would have disappeared.) Then a solution containing 15 grammes of levulose was injected into the stomach; four hours later the animal was killed. A large quantity of glycogen was found in the liver. In four other rabbits the experiment was repeated; they were kept for seven days without food. Two were killed, and to the two others were given 15 grammes each of levulose, and both were killed four hours later. No glycogen was found in the liver of the first two rabbits, but it was present in the liver of the two which had received the levulose.

From the above observations and experiments the author draws the following conclusions:

1. A patient suffering from chronic diabetes can utilize fifty grammes or more of levulose daily.

2. In some acute cases a part of the levulose taken with the food is excreted as such, a part is utilized in the body, and a part is transformed into glucose.

3. In rabbits, glycogen is formed from the levulose taken, and is stored up in the liver.

Hale White records the result of a number of careful experiments on eight diabetic patients with regard to the effect of giving levulose and inulin. Levulose prepared by Von Schering was employed, and inulin in the form of dahlia

tubers was given. The following are the conclusions at which he arrives:

1. If large amounts of levulose are given, some of it appears in the urine.
2. In none of these cases did levulose have the pernicious effect—often seen with ordinary carbohydrates—of increasing the output of sugar beyond the extra quantity given.
3. When levulose is given, the excretion of sugar is usually increased, but it may be diminished.
4. In most cases much less sugar is passed in the urine after giving levulose than would have been excreted if the previous excretion of sugar had remained stationary and all the levulose had appeared in the urine. This result seems to indicate that in these cases some of the levulose given was retained and used up in the body.
5. There is some evidence that the larger the amount of levulose the less will be the increase of sugar in the urine.
6. While, therefore, some of these cases show that levulose can be utilized better than dextrose, none of them show that dextrose can be utilized better than levulose.
7. None of the patients felt worse for taking levulose; indeed, some felt better and gained in weight.
8. Probably a moderate amount of dahlia tubers, taken as a vegetable by patients suffering from diabetes, would do no harm.
9. The effects of levulose on the excretion of urea is unimportant.
10. The amount of urine passed when levulose is given varies with the quantity of sugar passed.—*Medical Chronicle*, September, 1894.

#### MALARIA AND ITS THERAPEUTICS.

Previous to entering upon a short discussion as to the therapeutic value of the various drugs described as useful in malaria, FORBES, writing in the *Medical Press and Circular* of July 4, 1894, prefaces his statements by laying down as an axiom "that no single drug should be looked upon as a specific." Before passing to antipyretics, about which so much has been written of late, there is one drug—namely, "opium"—of the utmost use in prevention and cure of many malarious states. It has been stated, on what grounds we cannot conceive, that opium is useless in malaria, except to cure the pains. Not only the author's Indian and African experience proves this to be a false basis and a remark that could not be made truthfully by any practitioner with extended clinical

knowledge, but opium is acknowledged by the natives of India and many eminent Indian medical specialists to be of extreme value not only as a prophylactic, but also as a curative agent, by means of its sedative, anodyne, and perhaps most of all by its stimulant properties. These latter are contained in narcotine, which may be termed an extractive of opium; it has been used with some effect in these fevers. Opium is a wonderful stimulant in premonitory stages of fever, and in the case of those who have acquired the opium habit properly, so as to become regular consumers, it acts as a marvellous safeguard against dangerous attacks of fever, and even cholera, dysentery, etc. This is confirmed on all hands by Indian medical officers, some of whose evidence given before the Royal Commission on Opium has been published as extracts in the late numbers of the *British Medical Journal*. A full dose of morphine—say 1 drachm of liq. morphine acetatis—is reported by Surgeon-Lieutenant-Colonel Edward Lawrie, of Hyderabad, to have cut short cases of malarious remittent, the temperature in a few hours becoming normal or almost so, with the best results to the patient. Personally, the writer's experience was the same, having a severe attack of African remittent, temperature varying from 104° to 108° F., in spite of antipyrin and aconite. He took three hypodermic tabloids of morphine ( $\frac{1}{4}$  grain), one every thirty minutes, and next morning, after sleeping two hours, his temperature was much reduced and he felt almost well. At this juncture it must be premised that each drug does not appear, by observations noted in the tropics, to act in the same fashion as has been observed in temperate climates. And also that residence and practice in the tropics should be deemed the basis on which any knowledge of tropical disease can be acquired or that can enable the surgeon or physician to speak with any authority on these at all times obscure complaints, such as "sleeping sickness" of the Congo, etc. As an initial treatment,  $\frac{1}{16}$  grain of pilocarpine nitrat. will generally drench the patient with perspiration and will certainly abort an ordinary attack. He then reviews briefly the medicines generally used in treating these fevers: As antipyretic and anodyne, (1) antipyrin or phenazone is a most valuable drug in both senses, although the writer has to report one death in the Gold Coast Colony from its use; still, the dosage was high; the surgeon in attendance gave upward of one hundred grains in less than twenty-four hours. In this case it was also suspected that the patient had some fatty degeneration of the cardiac fibres. In any case,

in moderate doses, the remedy is most frequently valuable and non-toxic. The author's plan is to give never more than 10 grains, or even 5 grains repeated frequently, say every hour, and if temperature after a few hours shows no sign of fall, the drug should be stopped and recourse had to some other treatment.

Salicinum is a safe and reliable antipyretic; especially in those attacks which exhibit so-called rheumatic symptoms it is a perfect substitute for salicylate of sodium, without any of its dangerous properties.

Phenacetin he has used much and successfully, especially in India, but it is not so sure as antipyrin, and is much more liable to cause unpleasant and even dangerous symptoms. Care should be taken not to employ it in patients with organic heart-disease.

Antifebrin has been lauded as an antipyretic. His experience and that of others does not approve its use, as it is exceedingly liable to cause cardiac troubles and cyanosis.

Aconite in the form of tabloids of tinctura aconiti is reliable, which is more than can generally be said of the British Pharmacopœia tincture, and is undoubtedly the most successful remedy we have in both Indian and African remittents. It can be used when even antipyrin fails, as an anodyne, antipyretic, and analgesic; it is unsurpassed in these complaints by any other drug, and used in remittent fever may be termed "our sheet-anchor." It is poisonous, truly, but its control of the neuro-vascular mechanism is great, and it is, besides, the most powerful drug we have available in this class of disease.

Dover's powder, pulv. ipecac co., may be classed partly as a sudorific anodyne and partly as an antipyretic, and may be given, starting from the initial stage of fever, every hour in 5-grain doses.

Warburg's tincture, an empiric formula (containing opium, quinine, and aromatics), is without its equal in persistent and protracted agues, and can be used, as the author has done before antipyrin, etc., were known, with striking success in some of the worst forms of fever. It is also prophylactic against the return, when expected, of intermittent attacks. Those patients who can take it readily can be sure of great benefit accruing from its occasional use, but its taste is nauseous, unless taken in the tabloid form, quickly swallowed (dose,  $1\frac{1}{2}$  to 3 drachms). Should the administration of any or all of the above, given in succession, prove of no avail, our last resource, in strictly speaking antipyretic (it might here be almost called revulsant) treatment, is the cold bath or cold

wet pack. These, in skilful hands, have saved many lives, and even in the hands of tyros marked success has resulted.

Potassii bromidum is exceedingly useful in 10-grain doses, when severe headache marks initial stage; it is again useful in delirium, phrenetic symptoms which occur in the sanguine temperament, especially in those giving to overeating and heavy drinking. When vomiting supervenes, and this is common, especially in dysenteric and choleraic remittents, almost all drugs must be given hypodermically, as there is continuous vomiting and diarrhoea every few minutes. In one case the writer made considerable impression on the patient by repeated doses of chlorodyne in one of these choleraic attacks, giving  $\frac{1}{2}$ -drachm doses. Some of these were rejected, but some were retained, and the patient recovered, although his pulse was subnormal four hours after commencement of attack."

Hazeline, a distilled product from twigs of witch-hazel, is an almost unfailing hæmostatic; it also seems to act as an astringent to intestinal mucous membranes. It is pleasant to take internally, and can be given with good effect in hæmaturia, hæmatemesis, etc., which are frequent in pernicious attacks, both intermittent and remittent, the dose being 1 to 2 drachms. Should this fail, however, inject subcutaneously  $\frac{1}{16}$  grain of ergotin citrat.; this might be a specific. Ice, when it can be obtained, is also extremely useful, and also in acute dysentery.

Apomorphine hydrochlorate, in doses of  $\frac{1}{4}$  grain, would cut short an attack of bilious remittent by inducing vomiting. It is sometimes, but rarely, a good practice, vomiting being often only too persistent when once established.

Digitalis tincture has proved useful where heart shows signs of failure, and can be combined with advantage with liquor ferri perchloridi.

*Calomel.*—In one dose, from 5 to 10 grains, given at beginning of fever, when there is constipation.

*Methylene-Blue.*—Thayer, in 1892, tried small doses (2 or 3 grains for a dose) on several patients in intermittent fever, with satisfactory results; the drug in no wise gave rise to any unpleasant symptoms, and a cure (temporarily, at all events) resulted. Dr. Pucci says clinically he believes that quinine is responsible for many sequelæ of fever and for the development also of those ictere hæmaturic forms which are so fatal, whereas he used methylene-blue with far different and more successful results. Dr. Rosin confirms this.

Arsenous acid is useful in obstinate intermittents which are often rendered worse by quinine; dose,  $\frac{1}{100}$  grain of tabloids of acid arsenosi.

Quinine (quinine bisulphas) has been up till quite a recent date regarded as a specific, especially in the tropical forms of malarial fever, by even the most eminent and experienced practitioners. Its value as a specific in malaria is confirmed by the dicta of Laveran, Golgi, Hehir, Binz, Manson, and Baccelli (who considers it more powerful as a remedy when subcutaneously injected, and more likely to act directly on the "plasmodium malariae"). Dr. Beaven Rake says the intracorpular pigmented bodies are specially characteristic of acute forms of malaria, and are readily affected by quinine. This can hardly be substantiated by proof adequate against accumulated clinical evidence to the contrary from Europe (Rosin and Pucci), from equatorial Africa (Parke), and from India, wide enough fields for investigation. In his own clinical experience of hundreds of cases of tropical malaria, extending over years, Forbes finds that quinine given in acute malaria is almost as deadly as the disease.

#### THE HYPODERMIC ADMINISTRATION OF MERCURY.

The number of compounds of mercury which have been used by injection into the tissues is very large, and the author formulates the following rules for their safe employment:

All irritant or caustic preparations are, of course, inadmissible. The liquid injected must be chemically pure and sterile. The syringe must be sterilized in all its parts, and an unoxidizable needle (such as iridized platinum), not less than one and a half inches long, must be used. All injections must be given deeply into the tissues, the needle being inserted perpendicularly to the surface.

The lumbar portion of the back and the gluteal region are the best positions. Care must be taken not to introduce the syringe into a vein. Subsequent injections ought to be two to two and a half inches distant from a previous one.

The interval between each injection varies with the effect produced and the preparation employed,—from twice a day with small quantities of soluble preparations to once a month with large injections of insoluble preparations, such as calomel.

*Soluble Injections.*—Corrosive sublimate.

Corrosive sublimate, 1 part;  
Chloride of sodium, 6 parts;  
Sterilized water, 100 parts.

A Pravaz syringeful (about 15 minims) to be injected every day.

To avoid such frequent injections, M. Luke-siewicz injects  $\frac{1}{2}$  to 1 syringeful of a stronger solution every four or eight days. Corrosive sublimate can also be dissolved in sterilized oil, so that fifteen minims contain one-sixth of a grain, which is the usual dose.

Periodide of mercury is also well borne and causes little pain.  $\frac{1}{8}$  grain may be injected, dissolved in 15 minims of sterilized oil, and repeated every day or every other day, as the case may require.

*Succinimide of Mercury.*— $\frac{1}{8}$  grain in sterilized water may be given every day.

Sozoiiodolate of mercury is very active, but causes much pain. The following is Schwimmer's formula:

Sozoiiodolate of mercury, 8 parts;  
Iodide of potassium, 14 parts;  
Distilled water, 100 parts.

About 6 minims are injected every week, and the dose may be carefully increased.

#### Insoluble Injections.—Calomel.

Sublimated calomel, 1 part;  
Liquid vaseline, 10 parts.

15 minims to be injected every fifteen days.

Yellow oxide may be given in the same dose and manner as calomel.

Gray oil is less active than calomel.

Mercury (purified), 20 parts;  
Ethereal tincture of benzoin, 5 parts;  
Liquid vaseline, 40 parts.

$1\frac{1}{2}$  to 3 minims are injected every eight days.

Thymolate of mercury, 1 part, mixed with 10 parts of liquid vaseline, and 7 to 15 minims given every eight days.

Salicylate of mercury may be used like the thymolate.—MANNIAC, abstract from the *Medical Chronicle*, September, 1894.

#### SYMPHYSEOTOMY FOR THE RELATIVE INDICATION, WITH COMPLICATIONS.

DAVIS contributes to the *Boston Medical and Surgical Journal* of August 23, 1894, a paper upon this interesting topic. He thinks that in undertaking symphyseotomy in women older than thirty the operator must not trust wholly to the knife; this is the second case in the author's experience in which a condition of partial ossification has resisted the Galbiati

knife and probe-pointed bistoury. The occurrence of thrombosis during convalescence may be explained by the dislodgement of septic thrombi in the uterine sinuses, although it is not perfectly clear how such infected thrombi could cause no disturbance before the patient turned. A more rational explanation to the writer lies in mechanical injury in the sudden turn done to vessels predisposed to thrombosis by long recumbent posture, a retention dressing about the hips, and recovery from a surgical procedure of moderate severity. There was no evidence of abscess in any part of the thighs, which might readily have followed septic thrombosis. This illustrates well the importance of good nursing after symphyseotomy, without which the writer's patient's complicated labor would have been far more dangerous and trying.

The patient's pelvic measurements were such that delivery, possibly with forceps, was all that was anticipated; symphyseotomy was performed for the relative indication. The case impressed upon the operator and upon the class in clinic the futility of attempting to deliver a living child by forceps without symphyseotomy, when a relative disproportion in size between head and pelvis sufficient to prevent engagement exists.

#### NOTE ON THE PAST AND FUTURE OF VENESECTION.

When to let blood has from the earliest days of medicine been a burning question. The Saxon Leeches were divided on it, their difficulty being the phase of the moon most suitable for the operation. Two or more centuries later, rival schools of medicine held different views as to which side the patient should be bled, some contending that the side on which the inflammation existed was the proper one for venesection; the opponents of this view of the site for bleeding adduced many and learned arguments to prove that venesection was not efficacious unless performed on the side opposite to the inflammation. All this time, however, no physician questioned the value of venesection. The first shock to the medical profession practising this time-honored custom came from a layman, Alaric Renc le Sage, who caricatured the Sagredo of Espinal by the great doctor of Valladolid, Sangrado, who informed his pupil, Gil Blas, that "other physicians make the healing art consist in the knowledge of a thousand different sciences, but I go a shorter way to work, and spare the trouble of studying pharmacy, anatomy, bot-

any, and physic. Know, then, that all which is required is to bleed the patient copiously."

Patients appear to have enjoyed the operation. We read that Mary Anne, daughter of Don Jerome, of Quito, was bled, according to M. Guérin, five hundred times in the space of two years.

In the British Islands phlebotomists travelled the country, thatching houses, spaying sows, and bleeding. A spring and autumn venesection was considered a necessity. Young and old underwent the operation. Nor was the custom confined to this country. Italian families kept their bleeding vessels, and it was an accident of phlebotomy that gave Anel the opportunity for testing his operation for aneurism.

The operation was grossly abused for ages, and, as a consequence, the medical profession and the public became prejudiced against the lancet; it fell into disuse, and thus a useful and efficient therapeutic agent was disregarded.

We are now, however, coming to recognize that venesection has a place in practical medicine, and that the abstraction of a few ounces of blood is sometimes one of the most efficacious measures we can adopt. There is a general consensus of opinion in favor of a careful clinical study of the value of venesection.

The paper on venesection read by Dr. Pye-Smith before the Royal Medical and Surgical Society, in January, 1891, attracted much attention, and in the discussion that followed it was felt that Sir George Humphry voiced the opinion of every thoughtful member of the profession, "that bleeding was one of the most important agents in the treatment of disease." That, as stated by Dr. Pye-Smith, "the accumulation of experience would soon lead to the formation of an opinion as to the cases in which this measure was desirable," will meet with approval of the great majority of the profession at home and abroad, is noticeable from the discussions and papers on the subject appearing in foreign journals.

In the Royal Academy of Medicine in Madrid, Señor Iglesias recently made venesection the subject of a paper, which produced an animated discussion, in which Señor Palido fairly stated that not from any bad results of the operation, but from its abuse it became discredited, an opinion which re-echoes the view of the French Academy.

The operation also forms the subject of a valuable paper by Dr. Stone, in a late number of the THERAPEUTIC GAZETTE, in which, after reviewing at length the conditions which call for venesection, he concludes that he "sin-

cerely hopes that he has convinced some of his audience of the great therapeutic value of the remedy."

Sooner or later the lancet will again come to be a valued weapon in contending with inflammatory diseases.—FRY, in the *Medical Press and Circular*, July 4, 1894.

*THE TREATMENT OF CERTAIN SYMPTOMS OF CROUPOUS PNEUMONIA, PARTICULARLY IN ADULTS.*

ROBINSON has written an able clinical paper with this title. We append extracts from the more important passages, believing the article to be well worth careful study.

The two symptoms in connection with the first stage of croupous pneumonia which are of special interest as regards the efficacy of treatment are pyrexia and pulmonary congestion.

Personally, the writer has not thought it wise to give the modern antipyretic drugs, except in occasional doses. Of these, phenacetin is the most satisfactory. It diminishes fever somewhat and promotes sleep and the general comfort of the patient, without great risk of depression in a marked degree. Acetanilide, in doses of 2 to 3 grains, lowers temperature a degree or two, but without promoting the comfort of the patient or producing sleep. In doses of 5 grains or more it is evidently depressing. Neither of these drugs should be given continuously, and, as a rule, only when the temperature is over 103° F. Robinson relies very much more upon the use of spirits of Mindererus, citrate of potassium, and sulphate of magnesium to reduce temperature by action on the different emunctories of the economy—skin, kidneys, and bowels—than upon the former remedies. He believes still that 3 to 5 grains of quinine every four to six hours tend to diminish fever, while strengthening somewhat the heart, through diminution of local hyperæmia of the lungs, promotion of absorption of the fibrino-corpuscular exudation into the alveoli, and a possible antiseptic action on the blood itself.

As to the use of cold sponging, the ice coil, cold pack, or cool baths for the purpose of reducing temperature, he has come to the conclusion that they do not act in this manner with any special efficacy, as they are usually employed. In this country, at least, treatment of croupous pneumonia with cold baths has not yet become frequent. Occasionally, when the temperature passes beyond 104° F., and is accompanied with delirium, rapid and feeble pulse, frequent respiration, and other

evidences of intense poisoning or adynamia, the tub bath at a temperature of 80° or 90° F. may be usefully employed. Not that the temperature always falls much after the use of these baths, but, combined with continuous frictions during the bath, they certainly quiet delirium, awaken latent nervous energy, and stimulate capillary circulation over the surface of the body.

While these effects are customary, according to those who have made frequent use of cold tub-baths in the treatment of croupous pneumonia, until lately the author has been very doubtful as to their beneficial action. More than once he has seen bad rather than good results follow immersion. The patient has become more cyanosed, dyspnoea more marked, and, if anything, the pulmonary congestion more intense. He is inclined to believe that sponging is a decidedly wiser method than the tub-baths in many cases, if it be combined, too, with friction to help improve the patient's condition through its combined action in lowering the temperature slightly and in increasing nervous energy.

At St. Luke's Hospital the writer has had the opportunity to observe and carefully inquire into the use of aconitine when given at this stage, and often at a later period, with respect to its action on the temperature and pulse. After many trials of this drug, he has been led to believe that its use by itself may often be injurious by diminishing the energy of cardiac contractions, so that they are with some difficulty again strengthened. Even when combined in its use with digitalin, or digitalin and strychnine, it is not free at times from grave objections. Aconite or aconitine seems to act mainly by reducing the tension of the radial pulse and lessening the number of heart-beats, while it diminishes their strength by its paralyzing effect on the ganglia and nerves controlling cardiac contractions. This poisonous effect of aconite upon the heart through its motor ganglia may be shown by direct applications of the drug. As a result of these, the heart is slowed in a very threatening manner, and may stop in diastole.

The author has never seen any drug act as well in this stage of pneumonia as small repeated doses of antimony. The salt he has given most frequently is not tartar emetic, but kermes mineral, or the oxysulphuret of antimony. He has given it in a mixture with syrup of gum and orange-flower water, usually in doses of  $\frac{1}{2}$  grain every two hours, or every hour for a while; employed in this manner, fever and pulmonary congestion diminish at times in a very obvious manner. Expectora-

either paints the parts to be operated upon with a solution of antipyrin (2 parts), cocaine (1 part), and water to 10 parts; or, better still, paints with a ten-per-cent. cocaine solution, and injects a few minutes after in two or three places, under the mucous membrane in each place, 2 minims of a fifty-per-cent. antipyrin solution. Wroblowski was able to remove in this way, painlessly, lamellæ of a deviated nasal septum, operations which lasted half an hour; and the author confirms Wroblowski's statement that not only tonsils and adenoid vegetations may in this way be removed without pain, but that there is no pain afterwards. Wroblowski applies these solutions with similar good results in removal of the lingual tonsil,—a very painful procedure,—and after injecting a few drops of the antipyrin solution under the mucosa with a Heryng's laryngeal syringe, he is able to do painlessly prolonged laryngeal operations. The same application he has made in cases of tubercular ulceration of the larynx where deglutition has become painful and for solid substances impossible. In a patient of this sort, who had not been able to take solid food for about six months, one hour after the injection of a fifty-per-cent. antipyrin solution into the region of each arytenoid body (one division of a Heryng's syringe, equal to  $1\frac{1}{2}$  grains of antipyrin, being applied in each place), the patient was able to eat a beefsteak. Soon after the injection a slight burning sensation is felt. This lasts about fifteen minutes; then the local anæsthesia commences, and the loss of sensation lasts from six to twelve hours. The ulcerative tubercular process itself seemed to be favorably influenced by these injections. The author is applying at present, with similar favorable results, a paint (ten per cent. cocaine and thirty per cent. of antipyrin) twice a day to the larynx of a tubercular patient, in whom the deglutition of the saliva even had become extremely painful, and who is now able to take food and to swallow for six to eight hours after each application.

The local application of strong solutions of antipyrin to mucous membranes deserves, therefore, a much wider trial.

Where general anæsthesia is indicated for the removal of adenoids, attention might also again be drawn to bromide of ethyl, so ardently recommended by Hollaender at the Berlin International Medical Congress. This fluid,  $C_2H_5Br$ , has its boiling-point at  $105^\circ F.$ ; it therefore evaporates quickly; its odor is similar to chloroform. It was first used as a general anæsthetic by Thomas Nunneley, of Leeds, in 1869, who for some time did all his eye opera-

tions at the Leeds Infirmary with this anæsthetic. Since then it has been extensively used both in America and in France, mostly for dental operations. Unfortunately, several deaths have been recorded, but Hollaender and others ascribe these to the use of an impure preparation, as until recently it was somewhat difficult to obtain the pure drug, "ethyl bromide,"  $C_2H_5Br$ , owing to the frequent admixture of ethylene bromide,  $C_2H_4Br_2$ , a very poisonous drug. Hollaender administers ethyl bromide with an Esmarch chloroform inhaler, holding it closely over the mouth and nose to exclude air, and continually dropping the fluid on until anæsthesia is established, which takes place in thirty to forty seconds, and frequently in ten to twenty seconds. The anæsthesia so obtained is not complete, but is sufficient for small operations. The cornea reflex is not abolished, and it is not advisable to wait for its abolition, but only until the uplifted arm falls powerlessly down. Hollaender then at once proceeds to operate; the anæsthesia lasts two to three minutes, and the patient is in another minute fully awake. The pulse remains unaltered; it sometimes becomes even fuller; the pupils are not influenced; vomiting, a stage of excitement, headache, and other bad effects are said to be rare. From 1 to 3 drachms (3 to 10 grammes) of the drug are usually sufficient for an administration. A slow or continued administration of large doses causes considerable excitation and prevents a narcosis altogether. Though bromide of ethyl is said not to influence the heart, it should not be administered to patients with heart-disease. Schmidt also recommends this drug for anæsthesia in removal of adenoids and tonsils, but he finds that he usually requires a larger quantity of the anæsthetic. He has never seen any serious after-effects; but vomiting, he says, takes place occasionally. He therefore prefers to operate early in the morning, and not to give solid food previous to the operation. Schmidt also mentions that frequently the mouth is tightly closed, through contraction of the masseter muscles, so that a gag becomes requisite.

#### THE MANAGEMENT OF FACE PRESENTATION.

DAVIS, of the Jefferson College, in the *Medical News* of July 14, 1894, tells us that the treatment best adapted to secure spontaneous labor in face presentations consists in retaining the membranes unbroken until the time of spontaneous rupture; in sustaining the patient's

strength and conserving her energies by suitable feeding, stimulation, and anodynes, and in placing the patient in such a posture as to favor the rotation of the chin anteriorly. When the face looks towards the left side of the mother's pelvis, she should lie upon the left side, her thighs flexed, and the uterus brought as nearly as possible with its long axis corresponding to the axis of her body during labor-pains. Should the foetal face look towards the right side of her pelvis, she should lie upon her right side. The relation of cause and effect that has been found to exist between obliquity of the uterus in the mother's abdomen and face presentation renders the maintenance of the uterus in a favorable posture during this complication a matter of considerable moment. It is quite possible in such cases for a face presentation to be spontaneously changed into an occipital one, and for the occiput even to rotate spontaneously to the front, if these precautions are observed. The administration of such substances as tend to maintain efficient uterine contractions is certainly indicated in these cases before the membranes rupture. As soon as dilatation is complete, the obstetrician is to choose between radical interference by version, or an effort by the methods of Badelocque and Schatz to correct the face presentation by converting it into an occipital one. His choice in this decision should depend upon the size and shape of the mother's pelvis, the comparative size of the foetal head, and the condition of the pelvic floor. When no disproportion exists between the head and the pelvis, and when the pelvic floor, although elastic and resistant, offers no undue obstacle to the mechanism of labor, it is certainly proper to allow the head, under good labor-pains and with good extension, to come down upon the pelvic floor in face presentation, and thus an opportunity be given for the mechanism of labor to proceed spontaneously. When, however, there is a disproportion between the head and the pelvis, as evidenced by pelvic proportions less than the average, ascertained by pelvimetry or a large foetal head, as ascertained by palpation and a thorough vaginal examination under an anæsthetic, the case becomes quite different.

The results of forcible delivery in face presentations under these conditions are anything but satisfactory and encouraging. The literature of the subject abounds in illustrations of difficult deliveries by forceps, craniotomy, and, in some cases, by version, in which the life of the child has been lost and the mother seriously injured. In the light of our present knowledge,

the duty of the obstetrician lies in completely changing the presentation, if the pelvis be roomy, by podalic version under anæsthesia by chloroform, or in so enlarging the pelvis that the mechanism of labor in face presentation can continue.

Podalic version for face presentation is familiar as an expedient, and is, in well-selected cases, a prompt and efficient method of treatment. Symphyseotomy is a procedure of too recent date to occupy an established place in these cases in the resources of obstetric art. His resources for considering this a rational procedure are as follows: Personal observation in four symphyseotomies done for disproportion between the head and the pelvis has led him to remark the decided increase of the oblique diameters of the pelvis that follows the separation of the pubic joint. In three of the four cases the foetal head presented in an occipito-posterior position, in two cases the right occipito-posterior, in one the left. In one of these cases the head presented by the right parietal bone before the pelvis was opened. Remembering the observation by many obstetricians that face presentations are often developed out of occipito-posterior positions, it seems to the author rational that any surgical procedure which should enlarge the oblique diameters of the pelvis, and which naturally favors the descent of the occiput in the arc of the pelvic curve lying between the sacro-iliac joint and the spine of the pubes, would afford rectification of this abnormal presentation. The three cases of occipito-posterior position following symphyseotomy were readily delivered without injury to mother or child.

Obstetricians are familiar with the facility with which faulty presentations of the head and shoulders may be remedied when two conditions are present: first, complete anæsthesia of the mother; and, second, a pelvis of good size in its oblique diameters. Reasoning from the author's experience in the cases cited, these conditions are present after symphyseotomy; and were the spontaneous progress of labor in this presentation to fail, he should much prefer, if the pelvis were of good size and the head not impacted, to perform podalic version; or, if the head were impacted and disproportion existed between the head and the pelvis sufficient to occasion difficulty in labor, the face presentation persisting, the writer should hope for a favorable result from symphyseotomy, converting the face presentation into a vertex presentation, and delivering the occiput in the manner most easily available after the pubic joint had been opened.

## TREATMENT OF TYPHOID FEVER.

In the *Medical News* for July 14, 1894, FISK, of Denver, describes his treatment as follows; he has certainly obtained very good results:

Absolute rest. -If the patient is seen early in the attack, as gauged by the absence of rose spots and other constitutional symptoms, the writer gives 5 grains of calomel at night, and follows it with a Seidlitz powder or some saline in the morning, and this is the only administration of calomel during the progress of the disease. He then puts the patient on an absolute milk diet, giving a tumblerful every three hours. As a rule, the writer is not influenced by the patient's ideas that it is impossible to take milk, but determines that by his own observation. When he finds this to be true, he has the milk peptonized, and sometimes changes to buttermilk. Extractive matters in the way of broths and extracts are not used, as they always seem to be harmful.

The turpentine mixture used is becoming well known in our hospitals and is meeting with great favor. It is constituted as follows:

R. Ol. terebinthinæ, ℥jii;  
Ol. ricini, ℥jii;  
Bismuth subnit., ℥iii;  
Mucil. acaciæ, q. s. ad ℥iv. M.

This must be shaken well, and a teaspoonful given in a little water twenty minutes after the goblet of milk.

The turpentine in this formula seems to be sufficient to keep the tongue moist and to stimulate the bowels; the castor oil keeps up the secretions, and the bismuth acts, as is well known, as a dressing to the inflamed mucous surface; the last also has a constipating effect, which is overcome by the administration of castor oil (from a dessertspoonful to a table-spoonful) every other morning. For the restlessness of the first few days, which is especially marked at night, he uses either 5 grains of Dover's powder, to be repeated once or twice during the night, or 10 drops of McMunn's elixir of opium, to be repeated once or twice, if needed. Water, iced, if preferred, is given freely; lemonade, not too sweet, is allowed, but not to conflict with the taking of the milk. Antipyretics, like antipyrin, antifebrin, acetanilid, phenacetin, and even quinine (for its antipyretic effects), are absolutely forbidden. Stimulation he reserves for necessity, as indicated by marked nervousness, a rapid and feeble pulse, and for the stage of convalescence. In both instances whiskey is preferred, care being taken to secure a good quality. Of heart-tonics, strophanthus is given rather a preference, and at times he resorts to hypo-

dermic injections of strychnine. He has never used the cold baths of Brand; at the utmost, sponging with tepid water seems to be sufficient, though not often employed.

He believes that great care must be taken in feeding a patient in the stage of convalescence. He thinks it is well to keep him on the milk diet indicated, increasing, however, the amount, if needed, for a week after the temperature has come to the normal. He then begins to feed very gradually, preferring animal to starchy diet..

It will be seen that the methods employed are quite different from those advocated by others. The strict adherence to a milk diet is, of course, nothing new, and as far back as 1866 we find Dr. Cotting, of Roxbury, Mass., reporting in the London *Lancet* three hundred and seven cases of typhoid fever treated without drugs of any kind and a mortality of only ten per cent.

Professor Osler, in his recent publication, says, "Milk is the staple article of diet, of which from 3 to 4 pints are given in the twenty-four hours." This is about the amount the writer used.

Dr. Hutchinson says, "Milk as an article of diet is unquestionably to be preferred to all others in typhoid fever."

The administration of turpentine was advocated by the late Professor George B. Wood and indorsed by Dr. Hutchinson, though the dose employed was greatly in excess of that found in the turpentine mixture.

## THE COLD POULTICE AS AN ANTI-PYRETIC IN HIGH GRADES OF FEVER.

BEDFORD BROWN, in the *Virginia Medical Monthly* for September, 1894, advises the use of the cold poultice. He orders that a sufficient quantity of flaxseed meal to prepare a poultice of suitable dimensions be placed in a common earthen bowl, and over this is poured boiling water, while the meal is constantly stirred with a large spoon until cooked to the consistency of soft mush. This material is then spread on a piece of soft cotton cloth, for an adult, about eighteen inches long and twelve or fourteen wide, or sufficiently long to cover the entire abdomen, from the pubis upward, extending at least half-way up the chest, well over the cardiac region, so as to fully cover the heart and half of the chest. This poultice is now covered with another piece of cotton of corresponding dimensions. After being spread and covered, the entire surface to be applied

to the person is frequently besprinkled with ice-water until its temperature goes down to 68° or 70° F., when it is ready for application. At this point the author suggests that the poultice be not spread too thick, as in that case it would prove oppressive to the patient.

The poultice as thus prepared is applied over the chest, from above the cardiac region to the pubis. In the writer's experience with it, which dates back fifteen years, he has never known it produce shock to the nervous system or discomfort to the patient. On the contrary, patients with high fever, who have learned its advantages, will often request it when they feel sensations of rise of temperature. Its work, different from that of the cold bath, is accomplished slowly, gradually, gently, and effectually. The cold poultice applied in this way is a good substitute for the cold bath, without its many disadvantages, dangers, and difficulties of application.

In cases of fever, with a dangerous degree of hyperpyrexia, say 106° or 106.5° F., with delirium, insomnia, constant restlessness, contracted pupil, scanty, high-colored urine, these symptoms clearly indicate that this intense degree of temperature is exerting a destructive influence on the great nervous centres,—the brain and spinal cord; and if prompt measures are not taken to reduce this hyperpyrexia to a safe degree, the brain and spinal cord will be overwhelmed in hopeless ruin. This can only be accomplished either by the cold bath, internal antipyretics, or the cold poultice. In certain cases in the author's practice the latter measure, applied over the entire spinal column, from the cervical vertebræ to the sacrum, with these symptoms, has exerted a marvellous effect in relieving the nervous system, in subduing inordinate nervous erethism, relieving delirium and restlessness, and in promoting sleep.

In a case of this kind, during a relapse from a four weeks' illness, where the temperature approached 106° F., pulse 130, utter sleeplessness, and constant restlessness, a long poultice, at 70° F., was applied from above the cardiac region to the pubis; another, at the same temperature, ten inches wide, was applied over the nucha to the sacrum, and the head having been shaved, an ice-bag was applied over the head. In two hours there was a reduction of two degrees; in twelve hours a reduction of five degrees, with copious warm perspiration, with the result of refreshing sleep, nervous composure, relief of delirium; and reduction of the pulse to 100. On one or two occasions subsequently, when there was manifested a disposition of these symptoms to return, the same remedies were applied, with identical

results, and under the usual treatment the case terminated in recovery.

In the treatment of acute peritonitis the powers of the cold poultice have not been tested by him as an antipyretic and antiphlogistic. He believes that in this class of cases poultices, at a temperature of 70° F., applied systematically at intervals of one hour, would exert a beneficial influence.

There is a certain degree of art to be observed in the preparation of these poultices. They should not be spread so thick and heavy as to weight down the patient and cause a sense of oppression; not over a quarter of an inch in thickness, and then reduced to a uniform temperature, as tested by the clinical thermometer. In cases of temperature not exceeding 102° F., Brown often orders a cold poultice at first made with hot water, and then permitted to cool either by the atmosphere or application of ordinary hydrant- or pump-water, and obtains excellent results.

#### *SOME POINTS IN THE TREATMENT OF TYPHOID FEVER.*

In the *Medical Press and Circular* for August 22, 1894, BROADBENT writes on this topic. In intestinal hemorrhage the treatment on which the author has come to rely is the placing of a large ice bag over the right iliac fossa, the administration of a full dose of some liquid preparation of opium, and the subcutaneous injection of ergotin. 10 or 15 minims of turpentine may also be given every three or four hours. The object of the opium is to paralyze the bowel. The blood poured out into the intestinal canal excites peristalsis, and the peristalsis, in turn, tends to prevent the formation of clot on the bleeding surface, which might seal up the vessels. It must, therefore, be arrested; and it is because opium given by the mouth appears to effect this better than morphine hypodermically that this method of administration is preferred. ½ drachm of laudanum, or its equivalent of liquor opii, may be given at once. Opium, again, seems to have a certain sustaining power. Astringents, supposed to act directly on the bleeding vessels, are useless; long before they have traversed the twelve or sixteen feet of bowel to reach the ulcers they will have expended their power of coagulating blood or astringing tissues. When the medical man lives at a distance from the patient, the nurses should be provided with an ice bag, laudanum, and hypodermic pellets of ergotin, and have instructions to employ them immediately on the occurrence of serious hemorrhage.

every other day, or oftener. For a child one year old, the dose is from  $\frac{1}{16}$  to  $\frac{1}{8}$  grain in distilled water every evening at bedtime; for a child from two to three years old, the dose is from  $\frac{1}{8}$  to  $\frac{1}{4}$  grain [!—ED.]. By administering the alkaloid gradually—feeling one's way, as it were—no untoward accident should be anticipated. Adults, however, seem to be more susceptible to its influence than children. A good precaution is to remain with the patient from fifteen to twenty minutes after exhibiting the medicine, and when given to children, mothers should be instructed to use a little red wine or claret should the child show signs of weakness. He has seen only one man that complained of marked weakness after a hypodermic injection, and two patients were severely salivated. The first was restored by a little claret, and the other two were relieved by holding ice in the mouth.

It seems that in order for pilocarpine to be palliative or curative in acute or chronic urticaria, it must make the patient sweat freely. Free perspiration is promptly produced in an adult, and with a comparatively smaller dose than in a child, and herein is the guide to increase or diminish the dose.

To sum up:

1. Pilocarpine in urticaria is the drug *par excellence*.
2. Be sure of the diagnosis.
3. Before instituting your treatment, clear off complicating lesions.
4. Get a pure drug.
5. Have patience.
6. Push the drug to the point of tolerance.

In two cases of jaundice where the itching was quite annoying, pilocarpine proved useful; it also allays the burning and tingling sensations in other affections of the skin.

#### TREATMENT OF CYSTITIS IN WOMEN.

While in men the cause of cystitis is nearly always due to prostatic or urethral affections, in women it is due to inflammation following labor or operative traumatism. It may be acute or it may be chronic, and the following formulæ proposed by LUTAUD (*Revue Obstetricale et Gynécologique*, August, 1894) may be found useful in the acute form:

Morph. muriat., gr.  $\frac{1}{6}$ ;  
Extract, hyoscyamus, gr.  $\frac{1}{8}$ ;  
Coca butter, gr. xl.

For one suppository; 3 or 4 in twenty-four hours.

Irrigations of laudanum are soothing.

For the insomnia, chloral given as an injection:

Chloral hydrate,  $\mathfrak{z}$ i;  
Yellow of one egg;  
Water or milk,  $\mathfrak{f}\mathfrak{z}$ iiss.

The hypodermic injection of morphine (the patient never being permitted to make the injection herself) is still the best means of calming the paroxysms of pain. Cataplasms, baths, and hypogastric fomentations are useful. Topical applications in the vagina assist in allaying inflammation about the neck of the bladder:

Camphorated lanolin,  $\mathfrak{z}$ ii;  
Extract of belladonna,  $\mathfrak{z}$ i.

Saturate a tampon with the above and introduce night and morning into the vagina.

When the pain is intense, apply in the same way—

Muriate of cocaine, gr. xv;  
Distilled water,  $\mathfrak{f}\mathfrak{z}$ vi.

Internally, for the acute form:

Oxalic acid, gr. viii;  
Distilled water,  $\mathfrak{f}\mathfrak{z}$ iii;  
Syrup bitter orange-peel,  $\mathfrak{f}\mathfrak{z}$ i.

A dessertspoonful every four hours.

*Chronic Cystitis*.—Here the general as well as the local treatment should be employed, and only when the inflammatory phenomena and pain have subsided should one commence the irrigations.

The mild antiseptics hold first rank, as—

Boric acid,  $\mathfrak{z}$ i;  
Sodium bichlorate,  $\mathfrak{z}$ iss;  
Distilled water, Oii.

$\mathfrak{z}$ i to  $\mathfrak{z}$ ii are injected rapidly and allowed to flow away.

If the bladder is still irritable, use smaller amounts.

Injections of silver nitrate are but rarely employed; instead, iodoform is preferred, especially in cystitis of gonorrhoeal origin.

In such cases an injection of the boric-acid solution above mentioned is given; then follows an injection of 5 ounces of tepid water, containing a coffeespoonful of the following emulsion:

Iodoform powder, 30 parts;  
Glycerin, 40 parts;  
Distilled water, 20 parts;  
Gum tragacanth, .25 part.

Pyoktanin is also recommended in gonorrhoeal-cystitis, in the proportion of,—

Pyoktanin, gr. xv;  
Boiled and distilled water, Oii.

Inject morning and evening for from ten to fifteen days.

Constitutionally, in gonorrhoeal cystitis, extract of pichi is proposed by Wyman, and is thus employed:

Extract of pichi, 10 parts;  
Tr. cannabis indica, 2 parts;  
Lime-water, 90 parts.  
A dessertspoonful every four hours.

Or the following may be employed:

Bromide of ammonium, 10 parts;  
Tr. hyoscyamus, 5 parts;  
Fluid extract buchu, 10 parts;  
Distilled water, 60 parts.  
A coffeespoonful every four hours.

If there is pus in the urine, the following is useful:

Benzoic acid, 1 part;  
Orange-flower water, 50 parts;  
Boiled water, 900 parts;  
Sugar, 100 parts.  
Take by the glass between meals.

#### ICHTHYOL-ZINC PASTE AS A TREATMENT FOR ECZEMA OF THE FEMALE GENITALS.

In an article on eczema of the mucous membranes, VON SEHLEN (*Monatshfte für Praktische Dermatologie*, July, 1894) says that the inside of the vaginal sheath is especially subject to eczema, which continues outward to the labia, causing excessive itching. For the relief of this condition he proposes the following:

Ichthyol ammon.,  $1\frac{1}{2}$  to 2 parts;  
Amyli tritici,  
Zinc flor, of each, 12 parts;  
Vaseline, 25 parts.  
M. et fiat pasta.  
Sig.—Zinc-ichthyol paste.

Also calomel ointment of a high per cent. will often be useful in preventing the intense itching.

#### TREATMENT OF FURUNCULOSIS.

W. VAN HOORN (*Monatshfte für Praktische Dermatologie*, July, 1894) for many years has used the following method in cases of multiple furuncles, based upon general disinfection of the skin and isolation and disinfection of the affected area.

A general bath in warm water and soft soap is given; then the furuncles and the region about them are washed with a 1 to 1000 sublimate solution, dried with wadding (Bruns), and over the furuncle is applied a mercury-carbol mull plaster, after which the patient puts on a fresh suit of underclothing. Each day, or twice a day, the plaster is renewed; any soft points or perforations are lightly pressed, and contents washed away with the sublimate

solution. If there is no fluctuation, the infiltrate is rapidly reabsorbed; but if fluctuation is clear, perforation is the rule, but the healing is much hastened.

What is of especial importance is the non-appearance of new groups of furuncles, and when a single one now and then does break out, it is quickly reabsorbed.

#### TREATMENT OF PUERPERAL INFECTION.

BONNAIRE thus treats puerperal infection (*La Tribune Médicale*, July, 1894).

In all manipulations before, during, and after labor, scrupulously cleanse everything, from hands and instruments to bedlinen, that in any way may come in contact with the genitals of the patient.

Those who claim that the cause is always hetero-infection rely upon asepsis alone, but those who claim that the source of the microbes may be both hetero- and auto-infection rely upon antiseptics.

The author believes with others that auto-infection may be occasioned by the streptococcus, staphylococcus, gonococcus, or the colon bacillus, etc., and for that reason proposes antiseptics.

To avoid the entrance of the microbes, and their destruction when present after labor, a very feeble stream should be used in washing out the vagina, and the olive-tipped glass instrument used for the injections should be perforated only on the side.

Great care should be exercised that the canula contains no air, and from 3 to 4 quarts of a solution of sublimate (1 to 10,000) should be injected.

Carbolic acid is also a good antiseptic to use in these cases, in strength of at least two-per-cent. solutions.

Sulphate of copper is also a good drug, but possesses the same danger as the carbolic, in that they may both cause rapid poisoning when absorbed.

Bonnaire especially recommends the iodide and permanganate of potassium, iodoform, and phenosalyl. The following is an excellent way of using iodine:

R. Iodide of potassium,  $\text{ʒiiss}$ ;  
Metallic iodine,  $\text{mxxlv}$ ;  
Water,  $\text{ʒiijii}$ .  
Mix the whole in a quart of water.

Potassium permanganate is a good disinfectant, but less energetic than iodine.

in moderate doses, the remedy is most frequently valuable and non-toxic. The author's plan is to give never more than 10 grains, or even 5 grains repeated frequently, say every hour, and if temperature after a few hours shows no sign of fall, the drug should be stopped and recourse had to some other treatment.

Salicinum is a safe and reliable antipyretic; especially in those attacks which exhibit so-called rheumatic symptoms it is a perfect substitute for salicylate of sodium, without any of its dangerous properties.

Phenacetin he has used much and successfully, especially in India, but it is not so sure as antipyrin, and is much more liable to cause unpleasant and even dangerous symptoms. Care should be taken not to employ it in patients with organic heart-disease.

Antifebrin has been lauded as an antipyretic. His experience and that of others does not approve its use, as it is exceedingly liable to cause cardiac troubles and cyanosis.

Aconite in the form of tabloids of tinctura aconiti is reliable, which is more than can generally be said of the British Pharmacopœia tincture, and is undoubtedly the most successful remedy we have in both Indian and African remittents. It can be used when even antipyrin fails, as an anodyne, antipyretic, and analgesic; it is unsurpassed in these complaints by any other drug, and used in remittent fever may be termed "our sheet-anchor." It is poisonous, truly, but its control of the neuro-vascular mechanism is great, and it is, besides, the most powerful drug we have available in this class of disease.

Dover's powder, pulv. ipecac co., may be classed partly as a sudorific anodyne and partly as an antipyretic, and may be given, starting from the initial stage of fever, every hour in 5-grain doses.

Warburg's tincture, an empiric formula (containing opium, quinine, and aromatics), is without its equal in persistent and protracted agues, and can be used, as the author has done before antipyrin, etc., were known, with striking success in some of the worst forms of fever. It is also prophylactic against the return, when expected, of intermittent attacks. Those patients who can take it readily can be sure of great benefit accruing from its occasional use, but its taste is nauseous, unless taken in the tabloid form, quickly swallowed (dose,  $1\frac{1}{2}$  to 3 drachms). Should the administration of any or all of the above, given in succession, prove of no avail, our last resource, in strictly speaking antipyretic (it might here be almost called revulsant) treatment, is the cold bath or cold

wet pack. These, in skilful hands, have saved many lives, and even in the hands of tyros marked success has resulted.

Potassii bromidum is exceedingly useful in 10-grain doses, when severe headache marks initial stage; it is again useful in delirium, phrenetic symptoms which occur in the sanguine temperament, especially in those giving to overeating and heavy drinking. When vomiting supervenes, and this is common, especially in dysenteric and choleraic remittents, almost all drugs must be given hypodermically, as there is continuous vomiting and diarrhœa every few minutes. In one case the writer made considerable impression on the patient by repeated doses of chlorodyne in one of these choleraic attacks, giving  $\frac{1}{2}$ -drachm doses. Some of these were rejected, but some were retained, and the patient recovered, although his pulse was subnormal four hours after commencement of attack."

Hazeline, a distilled product from twigs of witch-hazel, is an almost unailing hæmostatic; it also seems to act as an astringent to intestinal mucous membranes. It is pleasant to take internally, and can be given with good effect in hæmaturia, hæmatemesis, etc., which are frequent in pernicious attacks, both intermittent and remittent, the dose being 1 to 2 drachms. Should this fail, however, inject subcutaneously  $\frac{1}{10}$  grain of ergotin in citrat.; this might be a specific. Ice, when it can be obtained, is also extremely useful, and also in acute dysentery.

Apomorphine hydrochlorate, in doses of  $\frac{1}{10}$  grain, would cut short an attack of bilious remittent by inducing vomiting. It is sometimes, but rarely, a good practice, vomiting being often only too persistent when once established.

Digitalis tincture has proved useful where heart shows signs of failure, and can be combined with advantage with liquor ferri perchloridi.

*Calomel.*—In one dose, from 5 to 10 grains, given at beginning of fever, when there is constipation.

*Methylene-Blue.*—Thayer, in 1892, tried small doses (2 or 3 grains for a dose) on several patients in intermittent fever, with satisfactory results; the drug in no wise gave rise to any unpleasant symptoms, and a cure (temporarily, at all events) resulted. Dr. Pucci says clinically he believes that quinine is responsible for many sequelæ of fever and for the development also of those ictere hæmaturic forms which are so fatal, whereas he used methylene-blue with far different and more successful results. Dr. Rosin confirms this.

Arsenous acid is useful in obstinate intermittents which are often rendered worse by quinine; dose,  $\frac{1}{100}$  grain of tabloids of acid arsenosi.

Quinine (quinine bisulphas) has been up till quite a recent date regarded as a specific, especially in the tropical forms of malarial fever, by even the most eminent and experienced practitioners. Its value as a specific in malaria is confirmed by the dicta of Laveran, Golgi, Hehir, Binz, Manson, and Baccelli (who considers it more powerful as a remedy when subcutaneously injected, and more likely to act directly on the "plasmodium malarie"). Dr. Beaven Rake says the intracorporeal pigmented bodies are specially characteristic of acute forms of malaria, and are readily affected by quinine. This can hardly be substantiated by proof adequate against accumulated clinical evidence to the contrary from Europe (Rosin and Pucci), from equatorial Africa (Parke), and from India, wide enough fields for investigation. In his own clinical experience of hundreds of cases of tropical malaria, extending over years, Forbes finds that quinine given in acute malaria is almost as deadly as the disease.

#### THE HYPODERMIC ADMINISTRATION OF MERCURY.

The number of compounds of mercury which have been used by injection into the tissues is very large, and the author formulates the following rules for their safe employment:

All irritant or caustic preparations are, of course, inadmissible. The liquid injected must be chemically pure and sterile. The syringe must be sterilized in all its parts, and an unoxidizable needle (such as iridized platinum), not less than one and a half inches long, must be used. All injections must be given deeply into the tissues, the needle being inserted perpendicularly to the surface.

The lumbar portion of the back and the gluteal region are the best positions. Care must be taken not to introduce the syringe into a vein. Subsequent injections ought to be two to two and a half inches distant from a previous one.

The interval between each injection varies with the effect produced and the preparation employed,—from twice a day with small quantities of soluble preparations to once a month with large injections of insoluble preparations, such as calomel.

*Soluble Injections.*—Corrosive sublimate.

Corrosive sublimate, 1 part;  
Chloride of sodium, 6 parts;  
Sterilized water, 100 parts.

A Pravaz syringeful (about 15 minims) to be injected every day.

To avoid such frequent injections, M. Luke-siewicz injects  $\frac{1}{2}$  to 1 syringeful of a stronger solution every four or eight days. Corrosive sublimate can also be dissolved in sterilized oil, so that fifteen minims contain one-sixth of a grain, which is the usual dose.

Periodide of mercury is also well borne and causes little pain.  $\frac{1}{16}$  grain may be injected, dissolved in 15 minims of sterilized oil, and repeated every day or every other day, as the case may require.

*Succinimide of Mercury.*— $\frac{1}{80}$  grain in sterilized water may be given every day.

Sozoiodolate of mercury is very active, but causes much pain. The following is Schwimmer's formula:

Sozoiodolate of mercury, 8 parts;  
Iodide of potassium, 14 parts;  
Distilled water, 100 parts.

About 6 minims are injected every week, and the dose may be carefully increased.

*Insoluble Injections.*—Calomel.

Sublimated calomel, 1 part;  
Liquid vaseline, 10 parts.

15 minims to be injected every fifteen days.

Yellow oxide may be given in the same dose and manner as calomel.

Gray oil is less active than calomel.

Mercury (purified), 20 parts;  
Ethereal tincture of benzoin, 5 parts;  
Liquid vaseline, 40 parts.

$1\frac{1}{2}$  to 3 minims are injected every eight days.

Thymolate of mercury, 1 part, mixed with 10 parts of liquid vaseline, and 7 to 15 minims given every eight days.

Salicylate of mercury may be used like the thymolate.—MANNIAC, abstract from the *Medical Chronicle*, September, 1894.

#### SYMPHYSEOTOMY FOR THE RELATIVE INDICATION, WITH COMPLICATIONS.

DAVIS contributes to the *Boston Medical and Surgical Journal* of August 23, 1894, a paper upon this interesting topic. He thinks that in undertaking symphyseotomy in women older than thirty the operator must not trust wholly to the knife; this is the second case in the author's experience in which a condition of partial ossification has resisted the Galbiati

knife and probe-pointed bistoury. The occurrence of thrombosis during convalescence may be explained by the dislodgement of septic thrombi in the uterine sinuses, although it is not perfectly clear how such infected thrombi could cause no disturbance before the patient turned. A more rational explanation to the writer lies in mechanical injury in the sudden turn done to vessels predisposed to thrombosis by long recumbent posture, a retention dressing about the hips, and recovery from a surgical procedure of moderate severity. There was no evidence of abscess in any part of the thighs, which might readily have followed septic thrombosis. This illustrates well the importance of good nursing after symphyseotomy, without which the writer's patient's complicated labor would have been far more dangerous and trying.

The patient's pelvic measurements were such that delivery, possibly with forceps, was all that was anticipated; symphyseotomy was performed for the relative indication. The case impressed upon the operator and upon the class in clinic the futility of attempting to deliver a living child by forceps without symphyseotomy, when a relative disproportion in size between head and pelvis sufficient to prevent engagement exists.

#### *NOTE ON THE PAST AND FUTURE OF VENESECTION.*

When to let blood has from the earliest days of medicine been a burning question. The Saxon Leeches were divided on it, their difficulty being the phase of the moon most suitable for the operation. Two or more centuries later, rival schools of medicine held different views as to which side the patient should be bled, some contending that the side on which the inflammation existed was the proper one for venesection; the opponents of this view of the site for bleeding adduced many and learned arguments to prove that venesection was not efficacious unless performed on the side opposite to the inflammation. All this time, however, no physician questioned the value of venesection. The first shock to the medical profession practising this time-honored custom came from a layman, Alaric Renc le Sage, who caricatured the Sagredo of Espinal by the great doctor of Valladolid, Sangrado, who informed his pupil, Gil Blas, that "other physicians make the healing art consist in the knowledge of a thousand different sciences, but I go a shorter way to work, and spare the trouble of studying pharmacy, anatomy, bot-

any, and physic. Know, then, that all which is required is to bleed the patient copiously."

Patients appear to have enjoyed the operation. We read that Mary Anne, daughter of Don Jerome, of Quito, was bled, according to M. Guerin, five hundred times in the space of two years.

In the British Islands phlebotomists travelled the country, thatching houses, spaying sows, and bleeding. A spring and autumn venesection was considered a necessity. Young and old underwent the operation. Nor was the custom confined to this country. Italian families kept their bleeding vessels, and it was an accident of phlebotomy that gave Anel the opportunity for testing his operation for aneurism.

The operation was grossly abused for ages, and, as a consequence, the medical profession and the public became prejudiced against the lancet; it fell into disuse, and thus a useful and efficient therapeutic agent was disregarded.

We are now, however, coming to recognize that venesection has a place in practical medicine, and that the abstraction of a few ounces of blood is sometimes one of the most efficacious measures we can adopt. There is a general consensus of opinion in favor of a careful clinical study of the value of venesection.

The paper on venesection read by Dr. Pye-Smith before the Royal Medical and Surgical Society, in January, 1891, attracted much attention, and in the discussion that followed it was felt that Sir George Humphry voiced the opinion of every thoughtful member of the profession, "that bleeding was one of the most important agents in the treatment of disease." That, as stated by Dr. Pye-Smith, "the accumulation of experience would soon lead to the formation of an opinion as to the cases in which this measure was desirable," will meet with approval of the great majority of the profession at home and abroad, is noticeable from the discussions and papers on the subject appearing in foreign journals.

In the Royal Academy of Medicine in Madrid, Señor Iglesias recently made venesection the subject of a paper, which produced an animated discussion, in which Señor Palido fairly stated that not from any bad results of the operation, but from its abuse it became discredited, an opinion which re-echoes the view of the French Academy.

The operation also forms the subject of a valuable paper by Dr. Stone, in a late number of the THERAPEUTIC GAZETTE, in which, after reviewing at length the conditions which call for venesection, he concludes that he "sin-

cerely hopes that he has convinced some of his audience of the great therapeutic value of the remedy."

Sooner or later the lancet will again come to be a valued weapon in contending with inflammatory diseases.—FRY, in the *Medical Press and Circular*, July 4, 1894.

*THE TREATMENT OF CERTAIN SYMPTOMS OF CROUPOUS PNEUMONIA, PARTICULARLY IN ADULTS.*

ROBINSON has written an able clinical paper with this title. We append extracts from the more important passages, believing the article to be well worth careful study.

The two symptoms in connection with the first stage of croupous pneumonia which are of special interest as regards the efficacy of treatment are pyrexia and pulmonary congestion.

Personally, the writer has not thought it wise to give the modern antipyretic drugs, except in occasional doses. Of these, phenacetin is the most satisfactory. It diminishes fever somewhat and promotes sleep and the general comfort of the patient, without great risk of depression in a marked degree. Acetanilide, in doses of 2 to 3 grains, lowers temperature a degree or two, but without promoting the comfort of the patient or producing sleep. In doses of 5 grains or more it is evidently depressing. Neither of these drugs should be given continuously, and, as a rule, only when the temperature is over 103° F. Robinson relies very much more upon the use of spirits of Mindererus, citrate of potassium, and sulphate of magnesium to reduce temperature by action on the different excretories of the economy—skin, kidneys, and bowels—than upon the former remedies. He believes still that 3 to 5 grains of quinine every four to six hours tend to diminish fever, while strengthening somewhat the heart, through diminution of local hyperæmia of the lungs, promotion of absorption of the fibrino-corpuscular exudation into the alveoli, and a possible antiseptic action on the blood itself.

As to the use of cold sponging, the ice coil, cold pack, or cool baths for the purpose of reducing temperature, he has come to the conclusion that they do not act in this manner with any special efficacy, as they are usually employed. In this country, at least, treatment of croupous pneumonia with cold baths has not yet become frequent. Occasionally, when the temperature passes beyond 104° F., and is accompanied with delirium, rapid and feeble pulse, frequent respiration, and other

evidences of intense poisoning or adynamia, the tub bath at a temperature of 80° or 90° F. may be usefully employed. Not that the temperature always falls much after the use of these baths, but, combined with continuous frictions during the bath, they certainly quiet delirium, awaken latent nervous energy, and stimulate capillary circulation over the surface of the body.

While these effects are customary, according to those who have made frequent use of cold tub-baths in the treatment of croupous pneumonia, until lately the author has been very doubtful as to their beneficial action. More than once he has seen bad rather than good results follow immersion. The patient has become more cyanosed, dyspnoea more marked, and, if anything, the pulmonary congestion more intense. He is inclined to believe that sponging is a decidedly wiser method than the tub-baths in many cases, if it be combined, too, with friction to help improve the patient's condition through its combined action in lowering the temperature slightly and in increasing nervous energy.

At St. Luke's Hospital the writer has had the opportunity to observe and carefully inquire into the use of aconitine when given at this stage, and often at a later period, with respect to its action on the temperature and pulse. After many trials of this drug, he has been led to believe that its use by itself may often be injurious by diminishing the energy of cardiac contractions, so that they are with some difficulty again strengthened. Even when combined in its use with digitalin, or digitalin and strychnine, it is not free at times from grave objections. Aconite or aconitine seems to act mainly by reducing the tension of the radial pulse and lessening the number of heart-beats, while it diminishes their strength by its paralyzing effect on the ganglia and nerves controlling cardiac contractions. This poisonous effect of aconite upon the heart through its motor ganglia may be shown by direct applications of the drug. As a result of these, the heart is slowed in a very threatening manner, and may stop in diastole.

The author has never seen any drug act as well in this stage of pneumonia as small repeated doses of antimony. The salt he has given most frequently is not tartar emetic, but kermes mineral, or the oxysulphuret of antimony. He has given it in a mixture with syrup of gum and orange-flower water, usually in doses of  $\frac{1}{2}$  grain every two hours, or every hour for a while; employed in this manner, fever and pulmonary congestion diminish at times in a very obvious manner. Expectora-

either paints the parts to be operated upon with a solution of antipyrin (2 parts), cocaine (1 part), and water to 10 parts; or, better still, paints with a ten-per-cent. cocaine solution, and injects a few minutes after in two or three places, under the mucous membrane in each place, 2 minims of a fifty-per-cent. antipyrin solution. Wroblowski was able to remove in this way, painlessly, lamellæ of a deviated nasal septum, operations which lasted half an hour; and the author confirms Wroblowski's statement that not only tonsils and adenoid vegetations may in this way be removed without pain, but that there is no pain afterwards. Wroblowski applies these solutions with similar good results in removal of the lingual tonsil,—a very painful procedure,—and after injecting a few drops of the antipyrin solution under the mucosa with a Heryng's laryngeal syringe, he is able to do painlessly prolonged laryngeal operations. The same application he has made in cases of tubercular ulceration of the larynx where deglutition has become painful and for solid substances impossible. In a patient of this sort, who had not been able to take solid food for about six months, one hour after the injection of a fifty-per-cent. antipyrin solution into the region of each arytenoid body (one division of a Heryng's syringe, equal to  $1\frac{1}{2}$  grains of antipyrin, being applied in each place), the patient was able to eat a beefsteak. Soon after the injection a slight burning sensation is felt. This lasts about fifteen minutes; then the local anæsthesia commences, and the loss of sensation lasts from six to twelve hours. The ulcerative tubercular process itself seemed to be favorably influenced by these injections. The author is applying at present, with similar favorable results, a paint (ten per cent. cocaine and thirty per cent. of antipyrin) twice a day to the larynx of a tubercular patient, in whom the deglutition of the saliva even had become extremely painful, and who is now able to take food and to swallow for six to eight hours after each application.

The local application of strong solutions of antipyrin to mucous membranes deserves, therefore, a much wider trial.

Where general anæsthesia is indicated for the removal of adenoids, attention might also again be drawn to bromide of ethyl, so ardently recommended by Hollaender at the Berlin International Medical Congress. This fluid,  $C_2H_5Br$ , has its boiling-point at  $105^\circ F.$ ; it therefore evaporates quickly; its odor is similar to chloroform. It was first used as a general anæsthetic by Thomas Nunneley, of Leeds, in 1869, who for some time did all his eye opera-

tions at the Leeds Infirmary with this anæsthetic. Since then it has been extensively used both in America and in France, mostly for dental operations. Unfortunately, several deaths have been recorded, but Hollaender and others ascribe these to the use of an impure preparation, as until recently it was somewhat difficult to obtain the pure drug, "ethyl bromide,"  $C_2H_5Br$ , owing to the frequent admixture of ethylene bromide,  $C_2H_4Br_2$ , a very poisonous drug. Hollaender administers ethyl bromide with an Esmarch chloroform inhaler, holding it closely over the mouth and nose to exclude air, and continually dropping the fluid on until anæsthesia is established, which takes place in thirty to forty seconds, and frequently in ten to twenty seconds. The anæsthesia so obtained is not complete, but is sufficient for small operations. The cornea reflex is not abolished, and it is not advisable to wait for its abolition, but only until the uplifted arm falls powerlessly down. Hollaender then at once proceeds to operate; the anæsthesia lasts two to three minutes, and the patient is in another minute fully awake. The pulse remains unaltered; it sometimes becomes even fuller; the pupils are not influenced; vomiting, a stage of excitement, headache, and other bad effects are said to be rare. From 1 to 3 drachms (3 to 10 grammes) of the drug are usually sufficient for an administration. A slow or continued administration of large doses causes considerable excitation and prevents a narcosis altogether. Though bromide of ethyl is said not to influence the heart, it should not be administered to patients with heart-disease. Schmidt also recommends this drug for anæsthesia in removal of adenoids and tonsils, but he finds that he usually requires a larger quantity of the anæsthetic. He has never seen any serious after-effects; but vomiting, he says, takes place occasionally. He therefore prefers to operate early in the morning, and not to give solid food previous to the operation. Schmidt also mentions that frequently the mouth is tightly closed, through contraction of the masseter muscles, so that a gag becomes requisite.

#### THE MANAGEMENT OF FACE PRESENTATION.

DAVIS, of the Jefferson College, in the *Medical News* of July 14, 1894, tells us that the treatment best adapted to secure spontaneous labor in face presentations consists in retaining the membranes unbroken until the time of spontaneous rupture; in sustaining the patient's

strength and conserving her energies by suitable feeding, stimulation, and anodynes, and in placing the patient in such a posture as to favor the rotation of the chin anteriorly. When the face looks towards the left side of the mother's pelvis, she should lie upon the left side, her thighs flexed, and the uterus brought as nearly as possible with its long axis corresponding to the axis of her body during labor-pains. Should the foetal face look towards the right side of her pelvis, she should lie upon her right side. The relation of cause and effect that has been found to exist between obliquity of the uterus in the mother's abdomen and face presentation renders the maintenance of the uterus in a favorable posture during this complication a matter of considerable moment. It is quite possible in such cases for a face presentation to be spontaneously changed into an occipital one, and for the occiput even to rotate spontaneously to the front, if these precautions are observed. The administration of such substances as tend to maintain efficient uterine contractions is certainly indicated in these cases before the membranes rupture. As soon as dilatation is complete, the obstetrician is to choose between radical interference by version, or an effort by the methods of Badelocque and Schatz to correct the face presentation by converting it into an occipital one. His choice in this decision should depend upon the size and shape of the mother's pelvis, the comparative size of the foetal head, and the condition of the pelvic floor. When no disproportion exists between the head and the pelvis, and when the pelvic floor, although elastic and resistant, offers no undue obstacle to the mechanism of labor, it is certainly proper to allow the head, under good labor-pains and with good extension, to come down upon the pelvic floor in face presentation, and thus an opportunity be given for the mechanism of labor to proceed spontaneously. When, however, there is a disproportion between the head and the pelvis, as evidenced by pelvic proportions less than the average, ascertained by pelvimetry or a large foetal head, as ascertained by palpation and a thorough vaginal examination under an anæsthetic, the case becomes quite different.

The results of forcible delivery in face presentations under these conditions are anything but satisfactory and encouraging. The literature of the subject abounds in illustrations of difficult deliveries by forceps, craniotomy, and, in some cases, by version, in which the life of the child has been lost and the mother seriously injured. In the light of our present knowledge,

the duty of the obstetrician lies in completely changing the presentation, if the pelvis be roomy, by podalic version under anæsthesia by chloroform, or in so enlarging the pelvis that the mechanism of labor in face presentation can continue.

Podalic version for face presentation is familiar as an expedient, and is, in well-selected cases, a prompt and efficient method of treatment. Symphyseotomy is a procedure of too recent date to occupy an established place in these cases in the resources of obstetric art. His resources for considering this a rational procedure are as follows: Personal observation in four symphyseotomies done for disproportion between the head and the pelvis has led him to remark the decided increase of the oblique diameters of the pelvis that follows the separation of the pubic joint. In three of the four cases the foetal head presented in an occipito-posterior position, in two cases the right occipito-posterior, in one the left. In one of these cases the head presented by the right parietal bone before the pelvis was opened. Remembering the observation by many obstetricians that face presentations are often developed out of occipito-posterior positions, it seems to the author rational that any surgical procedure which should enlarge the oblique diameters of the pelvis, and which naturally favors the descent of the occiput in the arc of the pelvic curve lying between the sacro-iliac joint and the spine of the pubes, would afford rectification of this abnormal presentation. The three cases of occipito-posterior position following symphyseotomy were readily delivered without injury to mother or child.

Obstetricians are familiar with the facility with which faulty presentations of the head and shoulders may be remedied when two conditions are present: first, complete anæsthesia of the mother; and, second, a pelvis of good size in its oblique diameters. Reasoning from the author's experience in the cases cited, these conditions are present after symphyseotomy; and were the spontaneous progress of labor in this presentation to fail, he should much prefer, if the pelvis were of good size and the head not impacted, to perform podalic version; or, if the head were impacted and disproportion existed between the head and the pelvis sufficient to occasion difficulty in labor, the face presentation persisting, the writer should hope for a favorable result from symphyseotomy, converting the face presentation into a vertex presentation, and delivering the occiput in the manner most easily available after the pubic joint had been opened.

## TREATMENT OF TYPHOID FEVER.

In the *Medical News* for July 14, 1894, FISK, of Denver, describes his treatment as follows; he has certainly obtained very good results:

Absolute rest. If the patient is seen early in the attack, as gauged by the absence of rose spots and other constitutional symptoms, the writer gives 5 grains of calomel at night, and follows it with a Seidlitz powder or some saline in the morning, and this is the only administration of calomel during the progress of the disease. He then puts the patient on an absolute milk diet, giving a tumblerful every three hours. As a rule, the writer is not influenced by the patient's ideas that it is impossible to take milk, but determines that by his own observation. When he finds this to be true, he has the milk peptonized, and sometimes changes to buttermilk. Extractive matters in the way of broths and extracts are not used, as they always seem to be harmful.

The turpentine mixture used is becoming well known in our hospitals and is meeting with great favor. It is constituted as follows:

R Ol. terebinthinæ, fʒii;  
Ol. ricini, fʒii;  
Bismuth subnit., ʒiii;  
Mucil. acaciæ, q. s. ad fʒiv. M.

This must be shaken well, and a teaspoonful given in a little water twenty minutes after the goblet of milk.

The turpentine in this formula seems to be sufficient to keep the tongue moist and to stimulate the bowels; the castor oil keeps up the secretions, and the bismuth acts, as is well known, as a dressing to the inflamed mucous surface; the last also has a constipating effect, which is overcome by the administration of castor oil (from a dessertspoonful to a table-spoonful) every other morning. For the restlessness of the first few days, which is especially marked at night, he uses either 5 grains of Dover's powder, to be repeated once or twice during the night, or 10 drops of McMunn's elixir of opium, to be repeated once or twice, if needed. Water, iced, if preferred, is given freely; lemonade, not too sweet, is allowed, but not to conflict with the taking of the milk. Antipyretics, like antipyrin, antifebrin, acetanilid, phenacetin, and even quinine (for its antipyretic effects), are absolutely forbidden. Stimulation he reserves for necessity, as indicated by marked nervousness, a rapid and feeble pulse, and for the stage of convalescence. In both instances whiskey is preferred, care being taken to secure a good quality. Of heart-tonics, strophanthus is given rather a preference, and at times he resorts to hypo-

dermic injections of strychnine. He has never used the cold baths of Brand; at the utmost, sponging with tepid water seems to be sufficient, though not often employed.

He believes that great care must be taken in feeding a patient in the stage of convalescence. He thinks it is well to keep him on the milk diet indicated, increasing, however, the amount, if needed, for a week after the temperature has come to the normal. He then begins to feed very gradually, preferring animal to starchy diet.

It will be seen that the methods employed are quite different from those advocated by others. The strict adherence to a milk diet is, of course, nothing new, and as far back as 1866 we find Dr. Cotting, of Roxbury, Mass., reporting in the London *Lancet* three hundred and seven cases of typhoid fever treated without drugs of any kind and a mortality of only ten per cent.

Professor Osler, in his recent publication, says, "Milk is the staple article of diet, of which from 3 to 4 pints are given in the twenty-four hours." This is about the amount the writer used.

Dr. Hutchinson says, "Milk as an article of diet is unquestionably to be preferred to all others in typhoid fever."

The administration of turpentine was advocated by the late Professor George B. Wood and indorsed by Dr. Hutchinson, though the dose employed was greatly in excess of that found in the turpentine mixture.

## THE COLD POULTICE AS AN ANTI-PYRETIC IN HIGH GRADES OF FEVER.

BEDFORD BROWN, in the *Virginia Medical Monthly* for September, 1894, advises the use of the cold poultice. He orders that a sufficient quantity of flaxseed meal to prepare a poultice of suitable dimensions be placed in a common earthen bowl, and over this is poured boiling water, while the meal is constantly stirred with a large spoon until cooked to the consistency of soft mush. This material is then spread on a piece of soft cotton cloth, for an adult, about eighteen inches long and twelve or fourteen wide, or sufficiently long to cover the entire abdomen, from the pubis upward, extending at least half-way up the chest, well over the cardiac region, so as to fully cover the heart and half of the chest. This poultice is now covered with another piece of cotton of corresponding dimensions. After being spread and covered, the entire surface to be applied

to the person is frequently besprinkled with ice-water until its temperature goes down to 68° or 70° F., when it is ready for application. At this point the author suggests that the poultice be not spread too thick, as in that case it would prove oppressive to the patient.

The poultice as thus prepared is applied over the chest, from above the cardiac region to the pubis. In the writer's experience with it, which dates back fifteen years, he has never known it produce shock to the nervous system or discomfort to the patient. On the contrary, patients with high fever, who have learned its advantages, will often request it when they feel sensations of rise of temperature. Its work, different from that of the cold bath, is accomplished slowly, gradually, gently, and effectually. The cold poultice applied in this way is a good substitute for the cold bath, without its many disadvantages, dangers, and difficulties of application.

In cases of fever, with a dangerous degree of hyperpyrexia, say 106° or 106.5° F., with delirium, insomnia, constant restlessness, contracted pupil, scanty, high-colored urine, these symptoms clearly indicate that this intense degree of temperature is exerting a destructive influence on the great nervous centres,—the brain and spinal cord; and if prompt measures are not taken to reduce this hyperpyrexia to a safe degree, the brain and spinal cord will be overwhelmed in hopeless ruin. This can only be accomplished either by the cold bath, internal antipyretics, or the cold poultice. In certain cases in the author's practice the latter measure, applied over the entire spinal column, from the cervical vertebrae to the sacrum, with these symptoms, has exerted a marvellous effect in relieving the nervous system, in subduing inordinate nervous erethism, relieving delirium and restlessness, and in promoting sleep.

In a case of this kind, during a relapse from a four weeks' illness, where the temperature approached 106° F., pulse 130, utter sleeplessness, and constant restlessness, a long poultice, at 70° F., was applied from above the cardiac region to the pubis; another, at the same temperature, ten inches wide, was applied over the nucha to the sacrum, and the head having been shaved, an ice-bag was applied over the head. In two hours there was a reduction of two degrees; in twelve hours a reduction of five degrees, with copious warm perspiration, with the result of refreshing sleep, nervous composure, relief of delirium; and reduction of the pulse to 100. On one or two occasions subsequently, when there was manifested a disposition of these symptoms to return, the same remedies were applied, with identical

results, and under the usual treatment the case terminated in recovery.

In the treatment of acute peritonitis the powers of the cold poultice have not been tested by him as an antipyretic and antiphlogistic. He believes that in this class of cases poultices, at a temperature of 70° F., applied systematically at intervals of one hour, would exert a beneficial influence.

There is a certain degree of art to be observed in the preparation of these poultices. They should not be spread so thick and heavy as to weight down the patient and cause a sense of oppression; not over a quarter of an inch in thickness, and then reduced to a uniform temperature, as tested by the clinical thermometer. In cases of temperature not exceeding 102° F., Brown often orders a cold poultice at first made with hot water, and then permitted to cool either by the atmosphere or application of ordinary hydrant- or pump-water, and obtains excellent results.

#### SOME POINTS IN THE TREATMENT OF TYPHOID FEVER.

In the *Medical Press and Circular* for August 22, 1894, BROADBENT writes on this topic. In intestinal hemorrhage the treatment on which the author has come to rely is the placing of a large ice bag over the right iliac fossa, the administration of a full dose of some liquid preparation of opium, and the subcutaneous injection of ergotin. 10 or 15 minims of turpentine may also be given every three or four hours. The object of the opium is to paralyze the bowel. The blood poured out into the intestinal canal excites peristalsis, and the peristalsis, in turn, tends to prevent the formation of clot on the bleeding surface, which might seal up the vessels. It must, therefore, be arrested; and it is because opium given by the mouth appears to effect this better than morphine hypodermically that this method of administration is preferred. ½ drachm of laudanum, or its equivalent of liquor opii, may be given at once. Opium, again, seems to have a certain sustaining power. Astringents, supposed to act directly on the bleeding vessels, are useless; long before they have traversed the twelve or sixteen feet of bowel to reach the ulcers they will have expended their power of coagulating blood or astringing tissues. When the medical man lives at a distance from the patient, the nurses should be provided with an ice bag, laudanum, and hypodermic pellets of ergotin, and have instructions to employ them immediately on the occurrence of serious hemorrhage.

threatened from peritonitis, the important point is careful cleansing of the entire peritoneum. The operation should be performed at the earliest possible moment,—that is, as soon as primary shock has passed off. The incision should always be in the middle line. The main efforts of the surgeon should be concentrated on cleansing the peritoneum. This is best accomplished by flushing. Normal saline solution or common salt, one drachm to the pint, affords the best medium; next to that is boiled water, to be used at 110° to 112° F. The flushing must be systematic; no time or care must be spared to make this flushing absolutely thorough; it is the essential vital step in the whole operation, the one upon which success or failure hinges. Where practicable, the hole in the stomach should be sewed up, Lembert's sutures being so passed as to invert the floor of the ulcer and a part of the surrounding walls. There appears to be no advantage in excising the ulcer or paring its edges. Should the ulcer be so placed that sutures cannot be placed efficiently, or if its edges are so widely infiltrated that they cannot be enfolded, the surgeon must choose between making a gastric fistula and simple drainage of the stomach; the latter is usually preferable,—i.e., pass one end of a tube into the ulcer and bring its other end out of the wound, and then pack it well round with iodoform gauze. Drainage should always be employed when peritonitis is well marked at the time of operating, the tube being placed in a separate wound above the pubes. Where there is any doubt as to the security of the gastric sutures, a large drain should also be placed with one end close to the ulcer.

When collapse occurs, and hot irrigations do not relieve it, intravenous injections of saline solution are indicated. Up to the present seven successful cases have been reported.

As to the subphrenic abscess, operation should be postponed until the abscess can be distinctly localized. Many of these ulcers run a chronic course, with no distinct indication of their exact position. It is better to wait until the position of the abscess is defined by swelling, or altered percussion-note, or other sign, when a free posterior opening should be made, if it is at all practicable.

Gould next took up the subject of perforation from typhoid ulceration of the intestine. Of seventeen reported cases there is one recovery. The details of operations are like those for perforative gastric ulcer. Perforation occurs most frequently in the third week of the disease, is usually single, and situated in

the ileum. Moreover, this complication may occur in the mildest cases, and causes twenty per cent. of the deaths in this disease. Symptoms may be fulminant or latent. Life is rarely prolonged beyond two days.

VAN HOOK's conclusions, which have appeared in a previous number of this journal, are quoted.

MACLAREN reported three cases of perforation of the stomach treated by operation, one successfully. He holds that it is not worth while to spend much time in washing out the stomach in these cases. He also emphasizes the importance of thorough cleansing of the abdominal cavity. This should be gone over systematically, and with a large, continuous stream. He begins in the neighborhood of the rupture, washes it thoroughly, then follows the course of the colon towards the cæcum, especially washing out below the liver. Next, beginning at the ulcer, the great bowel is followed to the rectum. The lumbar and pelvic hollows should receive special care. Finally, the douche is directed among the folds of the mesenteric attachments of the small intestines. It often happens that when all seems clear a fresh turn of the instrument will empty some unexpected pocket. The abdomen should be dried with sponges in the usual way. Feeding should be per rectum for a week.

MORRISON reported a case operated on by Aitchison. The ulcer was in the posterior wall. The patient died on the ninth day, of peritonitis limited to the pelvis.

BARLING reported three cases of perforation from gastric ulcer; two perished. The successful case was opened three weeks after operation for a circumscribed collection of pus in the left hypochondrium.

COUSINS incised and drained two cases with successful results.

HARRISON reported two cases of typhoid perforation. The first two perforations were found and closed; the patient perished in seventeen hours. The second case was not one of perforation, the symptoms having been caused by kink of the small intestine. The case recovered, although operated on in the acute stage of typhoid.

#### REVOLVER WOUND OF SKULL.

This case, reported by SCHWARZ (*Arch. de Laryngol.*, etc., July, August, 1894), was one of attempted suicide by means of two shots in the right fronto-temporal region. No apertures of exit were found. There was complete

consciousness, paralysis of the right abducens nerve, blindness of the right eye, and copious epistaxis. The man left the hospital in eleven days in good condition, but with a continuance of the ocular abnormalities. Six months later he returned, having had severe epistaxis at long intervals, and having become extremely anæmic. A severe epistaxis occurred, being most marked from the left nostril. The left external carotid was tied, and for some days there was no hemorrhage. Bleeding returned, however, most severely from the right nostril, and the right external carotid was ligatured. Two days later epistaxis returned as severely as ever. Schwarz felt sure that the blood came from the internal carotid artery, and determined to explore the cavity of the nose, which he exposed by Ollier's operation of turning this organ down. He was then able to pass his index finger into both sphenoidal sinuses, which communicated, where he found clots of blood. He plugged the sinuses with iodoform gauze, which he left for a fortnight. He then removed the plugs, and in less than another fortnight dismissed the patient free from his trouble. He made a good recovery.—*British Medical Journal*, October 6, 1894.

#### STERILIZATION OF CATGUT.

EASTMAN (*Annals of Surgery*, vol. xx., No. 1, 1894) sterilizes catgut by heating it to  $212^{\circ}$  F. for three hours in olive oil. He claims that a strong, smooth, absolutely sterile catgut is thus prepared.

#### CRANIECTOMY IN MICROCEPHALUS.

BECK (*Journal of the American Medical Association*, November 3, 1894) concludes a very thorough statistical study upon the subject of craniectomy in microcephalus as follows:

Craniectomy is a justifiable operation and apt to be successful in the treatment of microcephaly with idiocy.

The success depends on the kind of microcephaly and the degree of idiocy.

Acquired and late forms give a better prognosis than congenital forms.

The danger of the operation is not very great.

The operation ought to be quite extensive,—that is, the incision in the skull large enough to permit dilatation,—and the circular method of Gersuny ought to be given a trial.

The patients must be given a thorough pedagogic treatment afterwards.

The single cases ought to be followed up for years and reported from time to time.

The mortality in seventy-two reported cases is seventeen per cent. The dangers of operation are shock, hemorrhage, and infection. As a means of lessening shock, chisel and hammer should be discarded. The operation should be pushed as rapidly as possible, and hot applications to the head are advisable. Hemorrhage may be serious, but is rarely so. Bleeding from the skull can be checked by an Esmarch rubber band fastened tightly around the head. Should the dura be injured it must be sewed.

Of the twelve fatal cases, death was due in six to shock, one to heart failure, one to loss of blood, two to infection, and in two no cause was assigned.

#### OPERATION IN PERITONEAL ADHESIONS.

NICAISE (*Rev. de Chir.*, August, 1894) states that the use of antiseptic methods and the consequent development of antiseptic surgery have made surgeons better acquainted with peritoneal adhesions, and have led to their successful treatment by operation. These adhesions may give trouble by disturbing the functions of implicated organs and by exciting pain. The painful sensations vary in character and intensity in different cases. They may be caused by displacement of the organs to which the adhesive bands are attached, or by constriction of the intestinal canal. The pains in the latter condition are often very severe, and of a similar nature to those of hepatic and renal colic. The diagnosis of peritoneal adhesions is often very difficult; in some cases their existence can be assumed only by a process of exclusion, whilst in others, certainty as to their presence or absence cannot be attained except by an exploratory laparotomy. The author is of opinion, however, that a diagnosis may be made in many cases by close inquiry concerning such details as the previous occurrence of abdominal inflammation, the seat of the pain, and the relation of such seat to that of old inflammatory attacks; the time when the pain comes on with regard to the taking of food, and, in females, to the periods of menstruation. As many peritoneal adhesions become longer and thinner, and have a tendency to disappear, there should be no hurry in having recourse to operative treatment. When, however, they cause very severe and frequently renewed pain, although the

compression of an abdominal belt or bandage or massage may give relief, the only method of dealing effectually with such trouble is the performance of laparotomy and the destruction of the adhesions. The cure that may be thus effected will be complete and permanent; but, it is pointed out, as laparotomy is a serious operation, unless practised under very strict antiseptic conditions, it ought not to be applied in cases of peritoneal adhesions unless these cause intolerable pain.—*British Medical Journal*, October 20, 1894.

---

## Reviews.

---

PRACTICAL URINALYSIS. By Charles W. Purdy, M.D. Illustrated.

Philadelphia: The F. A. Davis Company, 1894.

Dr. Purdy is very well known to many members of the profession for his valuable contribution to the study of diabetes and to some extent for his work in urinary analysis. The present volume, while it adds nothing of very great note to the subject of which it treats, is a well written, accurate contribution to the literature of the subject.

We can heartily recommend the book to those of our readers who wish a complete manual and who desire a volume which will aid them in their microscopical studies by reason of the many illustrations which it contains, quite a number of which are colored.

THE PHYSICIAN'S VISITING-LIST FOR 1895. Forty-fourth year of its publication.

Philadelphia: P. Blakiston, Son & Co., 1895.

When a visiting-list has obtained the popularity of Blakiston's, nothing more is necessary at the beginning of each season than the announcement that the publishers have continued its issuance as in previous years. While maintaining all the advantages which it has possessed in the past, nothing new has been added to the present issue which is worthy of notice, and the words of praise which we gave last year's issue are entirely applicable to the publication for 1895.

ESSENTIALS OF DISEASES OF THE SKIN. By Henry W. Stelwagon, M.D., Ph.D. Third edition, revised and enlarged.

Philadelphia: W. B. Saunders, 1894.

If there is any subject which lends itself readily to the form of questions and answers, it is probably dermatology, and Dr. Stelwagon

has utilized the possibilities of this form of book-making to the highest degree in preparing his little manual. The half-tone illustrations which have been introduced into this edition very materially increase its value, while the clear and concise descriptions concerning the diagnosis and treatment of various skin-affections, endorsed as they are by the author's wide experience, render any advice he may give reliable and accurate. We doubt not that Dr. Stelwagon's book will continue to grow in popularity.

A SYNOPSIS OF THE PRACTICE OF MEDICINE. By William Blair Stewart, A.M., M.D.

New York: E. B. Treat & Co., 1894.

We regret that we cannot review this book as favorably as we would like to do. It gives evidence of crudity in style and expression which condemns it as a book for the student, and in many places is so imperfect in its description of the diagnosis and treatment of disease as to convey an erroneous idea to the mind of the reader. Thus, under the head of Parotitis, the only point named under diagnosis is the eating of a sour pickle or lemon. Under Tetanus, we are told that it is *probably* due to a micro-organism, which is hardly the present view of the case.

We are surprised to find under the same character of head as is found at the top of the description of each disease, the word Tuberculin, which might, therefore, be considered by the tyro as a disease and not as a remedy.

TEXT-BOOK OF MEDICAL CHEMISTRY FOR MEDICAL AND PHARMACEUTICAL STUDENTS AND PRACTITIONERS. By Elias H. Bartley, B.S., M.D. Third edition, revised and enlarged. Illustrated.

Philadelphia: P. Blakiston, Son & Co., 1894.

The student of medicine often finds in medical chemistry much that is difficult to understand, especially if his knowledge of general chemistry is limited.

The arrangement of a book, the definitions, etc., add much to its value. Many books contain much that is valuable, but the subject-matter is presented in such a manner as to confuse instead of making clear to the student the subject discussed. In this book the author has not only demonstrated his thorough knowledge of the subject, but has written in a manner which clearly shows him to be a teacher as well as a writer, by placing that which is essential in such a manner as to at once arrest the attention of the student.

The greater part of this book is necessarily a compilation, differing only in individuality in

presentation from other works, yet much has been added which is new and of practical value. The book is arranged to cover the more extended course now given in most medical colleges.

The chapter on physiological and clinical chemistry is the most valuable addition in this edition, especially that portion devoted to the examination of urine. The appendix contains many valuable and useful tables. In this third edition the author deserves the same support of the profession which his previous editions have merited.

D. B. K.

**ESSENTIALS OF CHEMISTRY AND TOXICOLOGY.** By R. A. Witthaus, A.M., M.D. Twelfth edition. New York: William Wood & Co., 1894.

In sixteen years twelve editions of this very diminutive little quiz-book, which is arranged in the form of questions and answers, have been called for. Just small enough to fit a pocket, we can readily understand how medical students have pored over its pages in brief moments of leisure when they wished to refresh their memories as to some major point which had slipped from them in the hurry of their other work. Professor Witthaus is too successful a teacher to wish his students to depend upon so small and incomplete a book for their chemical knowledge, and has, as is well known, prepared a larger volume, which, in popularity, has almost equalled the minute one we are now noticing.

**A MANUAL OF HUMAN PHYSIOLOGY. PREPARED FOR STUDENTS OF MEDICINE.** By Joseph H. Raymond, A.M., M.D. Illustrated. Philadelphia: W. B. Saunders, 1894.

The author of this little octavo volume of less than four hundred pages tells us in his preface that a long experience with medical students has brought him to the conclusion that some very thorough and brief work upon physiology would be of particular value to them. He has therefore attempted to cover this important subject in the brief space which we have named.

The volume is larger than a quiz-book and far smaller than a complete text-book, and we do not think that for these and other reasons it can be recommended either to the student or graduate, as the statements which it contains are so exceeding concise as to be imperfect, and its character is too elementary for the student of medicine to obtain a sufficiently deep knowledge of this fundamental subject in medical study. We doubt not that it may prove useful to classes in physiology in high schools or similar institutions.

**A CLINICAL MANUAL AND GUIDE TO THE PRACTICAL EXAMINATION OF THE EXCRETIONS AND SECRETIONS AND OF THE BLOOD. FOR THE USE OF PHYSICIANS AND STUDENTS.** By Andrew MacFarlane, A.M., M.D. New York: G. P. Putnam's Sons, 1894.

This book, which is a small octavo and contains less than one hundred and fifty pages, is, we think, one of the best brief summaries of clinical diagnosis that has been published for some years. It is copiously illustrated, and describes carefully the most recent means employed in urinary and other examinations, as, for example, the employment of the centrifuge. The various well-recognized tests in clinical analysis are carefully but briefly given, and a sufficient number of illustrations, colored and otherwise, are introduced to properly elucidate the text. Whenever there is a possible source of error in the tests which are suggested these possibilities are carefully pointed out.

We can heartily recommend the book to the busy, active practitioner, as giving him in a nutshell the necessary points in clinical diagnosis which he needs in daily practice.

**PRESCRIBING AND TREATMENT IN THE DISEASES OF INFANTS AND CHILDREN.** By Philip E. Muskett. Third edition.

Edinburgh: Young K. Pentland, 1894.

After looking over this book and the numerous polypharmaceutical prescriptions which it contains, we cannot avoid calling attention to the author's name and its similarity with what is known as the "shot-gun prescription." In many instances, however, the compiler has obtained from the writings of recognized authorities upon pediatrics very valuable diagnostic and therapeutic points, and the book is therefore not as bad in its influence as might be imagined by a brief glance at its pages. We doubt very much whether it will prove of much value or interest to the American practitioner.

The first half of the book is taken up with the various drugs and other applications to children's diseases and the second half to the treatment of disease in infants and children, while the end, which is known as Part III., perhaps forms the most valuable portion of the brochure, giving a number of recipes.

**LOCAL ANÆSTHETICS AND COCAINE ANALGESIA: THEIR USES AND LIMITATION.** By Thomas H. Manley, A.M., M.D.

St. Louis: J. H. Chambers & Co., 1894.

Dr. Manley is such an enthusiastic worker in surgery that we regret having to adversely criticize his contribution to this important subject. In his dedication he tells us that the book is a "hurriedly written contribution," which is an admission of a fact which any one who reads

the pages speedily discovers, and his remark in his preface, that the age is one of "lightning progress," should, we think, have caused him, in writing upon so new a subject, to do as St. Paul did, "cast four anchors out of the stern and pray for the day." That care should be exercised in writing a book dealing with so important a topic is evident to every one, and the neglect of such care fails to render medicine the service which Dr. Manley is so well capable of rendering.

We hope that, should the book ever come to a second edition, Dr. Manley will go over its pages and carefully revise them from the point of view of the surgeon and *littérateur*.

A COMPEND OF THE PRACTICE OF MEDICINE, CONTAINING A SECTION ON SKIN-DISEASES AND ONE UPON MENTAL DISEASES. By Daniel E. Hughes, M.D. Fifth edition, thoroughly revised and enlarged.

Philadelphia: P. Blakiston, Son & Co., 1895.

This book has now been before the profession for some twelve or thirteen years, and has, as our heading indicates, been revised a number of times by its author, who has endeavored to compass the difficult task of putting in all the new things in medicine without increasing the size of the book to the dimensions of a text-book. He has also changed its character somewhat from that of a compilation of the views of others, in that he has included in many instances the results of his own personal experience, which has naturally been rich, because of the opportunities which he has had as the chief resident physician in one of the largest hospitals in the world. The volume, which is a small octavo of five hundred and sixty-eight pages, is the best of its kind with which we are acquainted, and we heartily recommend its use by the student, provided he will also employ as his chief source of learning the lectures upon the practice of medicine which he is supposed to attend and the large and complete text-books on practice which all good medical institutions recommend to their classes.

TEXT-BOOK OF HYGIENE. By George H. Rohé M.D. Third edition, thoroughly revised and largely rewritten. Illustrated.

Philadelphia: The F. A. Davis Company, 1894.

The third edition of Dr. Rohé's book on Hygiene has been enriched by a new chapter on Quarantine by Surgeon-General Wyman and Dr. Geddings, of the United States Marine Hospital Service, while Dr. Gihon, of the navy, has revised his original chapter upon Marine Hygiene, and Dr. Egbert, of Philadelphia, that upon Vital Statistics.

Up to the time of the publication of the

book on Hygiene by Coplin and Bevan, which was published about a year ago, there was no volume published in this country which in character and price made it suitable to use as a text-book in a medical school. We now have two contributions by American authors of which the profession in this country may be proud. The present volume contains about five hundred and fifty pages, and is printed in unusually large type on good paper.

---

## Notes and Queries.

---

### DIPHTHERIA ANTITOXINE.

We are glad to be able to announce that Parke, Davis & Co., of Detroit, are engaged in the preparation of diphtheria antitoxine. As it requires a considerable length of time to prepare the serum, they are unable to provide it at once, but expect to be able to supply the profession very shortly.

---

### THE INDEX MEDICUS.

The *Index Medicus* will cease to be published with the February number, owing to lack of support and the fact that a large number of its subscribers are delinquent, *unless an effort is made to continue it*.

The value of this publication to those who do any work at all in connection with medical literature is so great that it should receive the hearty support of the profession, and it is hoped that a sufficient number of persons will become subscribers to permit of its continuance.

This is particularly necessary, owing to the fact that, after the completion of the supplementary volumes of "The Index Catalogue of the Surgeon-General's Library," there will be no record of contemporary medical literature, and he who desires to keep pace with it, or who wishes to study a particular subject, will have to resort to the laborious task of seeking in various journals that which he desires, if the publication of the *Index Medicus* ceases.

It will be possible to continue the *Index Medicus* if only five hundred new subscribers are obtained, and as the use of the *Index* is world-wide, this should be readily accomplished. The subscription price is ten dollars per annum, which should be sent to Mr. George S. Davis, publisher of the *Index Medicus*, Box 470, Detroit, Michigan, U.S.A.,
